

Reports on Surveys with the
R/V Dr Fridtjof Nansen

A Joint Programme NORAD and UNDP/FAO GLO/82/001

SURVEY OF THE ABUNDANCE AND DISTRIBUTION OF THE
FISH RESOURCES OF CONGO AND GABON

REPORT OF CRUISE NO.2

30 MAY TO 12 JUNE

1985

August 1985

1. INTRODUCTION

Under an agreement between the Governments of Congo and Gabon, the United Nations Food and Agricultural Organisation (FAO) and the Norwegian Agency for Development Aid (NORAD) the fishery research vessel DR FRIDTJOF NANSEN will conduct a series of surveys of the fish resources of Congo and Gabon. This work forms part of the UNDP/FAO programme GLO/82/001.

This cruise report is the second of a series of interim reports to be issued upon the completion of each individual survey. The surveys will be further analysed in investigational reports.

The following scientific personell participated:

From IMR Bergen:

O. Haldorson (cruise leader), K. Pittman, H. Ullebust
T. Haugland (instrument chief), E. Molvær

From Congo:

Prosper Mfina, Francois Bileko

From Gabon:

Leon Mba Nguema, Jean Alhogo Nang

From Zaire:

Enganya Mpia Wango

2. NARRATIVE

The vessel departed pointe Noire on 30 May at 1700 hours. The shelf was covered northwards with an acoustic survey grid with approximately 10 nm between the transects. Semi random bottom trawl stations were laid out along the cruise track during daylight to assess the demersal biomass by the so called swept-area method. The area just south of Cape Lopez is restricted due to heavy oil drilling activities. This area was not surveyed as no permit to navigate there had been received. A call was made on Owendo on 11 June where the Gaboneese scientists disembarked. Thereafter the cruise continued to the northern Gaboneese border. The vessel arrived Port Gentile on 12 June to disembark crew and remaining scientists and for layup. Fishing stations included 49 bottom trawl stations and 22 pelagic trawl stations. The total distance surveyed was 2000 nm.

3.HYDROGRAPHY

The positions of the three hydrographic transects taken off the Congo Gabon coast are shown in Figure 1. Figure 2 shows the distribution of temperature, salinity and oxygen in each section. The surface temperature increased northwards, lowest off Pointe Noire, 20 C and highest on Equator (27 C). The termocline for all the hydrographical sections lay between 30 and 50 m. The sharpest termocline was observed on Equator, but off Pointe Noire and Pte Milango the temperature decreased more gradually with depth. As shown in the figures, the oxygen content decreases with depth, however values below 1 ml/l are found only beyond the continental shelf and should thus not limit the fish distribution on the shelf.

4. FISH DISTRIBUTION AND ABUNDANCE.

The acoustic data from the echo sounders and integrators are processed

and classified in a procedure based on experience of the types of echo recordings produced by various forms of organisms and on the information gained from the fishing experiments. Three categories are usually distinguished:

1. Pelagic fish type I : Clupeids e.g. sardinellas, sardines, anchovies.
2. Pelagic fish type II: Other schooling pelagic fish such as horse mackerel, other carangids, scombrids, hairtails, barracudas etc.
3. Demersal fish : Other than pelagic schooling fish such as hakes, sparids, sciaenids, catfishes, snappers etc.

In addition signals caused by plankton and by mesopelagic fish such as myctophids are recorded, but no further processing is being made of these data.

Assessment of the abundance of fish resources based on acoustic observations combined with experimental fishing is a method which especially lends itself to fish found in schools or other aggregations in mid water. Fish close to the bottom will not be detected by the echosounder, nor will fish in the very surface layer, but schools may be detected by horizontal ranging sonar. For navigational reasons the work with the R/V "Dr. Fridtjof Nansen" is limited to waters deeper than about 15m. The effects of any of these factors on the acoustic assessment will be towards an underestimate of the actual resources.

A common feature during the survey was the presence of very dense registrations of plankton which screened the faint traces of the fish resources. This will effect the precision of the acoustic estimates and makes the trawl survey assessment useful for comparison.

During this survey the abundance of the pelagic resources was very low and it was not considered meaningful to separate the pelagic recordings into Pelagic I and Pelagic II as introduced above.

Figure 3 shows the distribution of pelagic fish while Figure 4 shows the demersal resources recorded by the acoustic system. Where pelagic resources were found they were generally of low level and no true fish schools were located which could form basis for large scale fisheries. The only exception from the very scattered registrations was a few Sardinella aurita schools off Madingo. In the area from Pointe Noire to Sette Cama the pelagic resources in shallow waters consisted of Chloroscombrus chrysurus, Ilisha africana, Sphyraena gauchancho and Selene dorsalis, while Trachurus trecae and Decapterus rhonchus dominated the outer shelf. In the area from Cape Lopez to the northern Gaboneese border, the triggerfish, Balistes capriscus was the most dominant species within the pelagic group. In shallow waters north of Sette Cama to just north of Iguela small juveniles of Brachydeuterus auritus, Sardinella maderensis, S. aurita and Decapterus sp. were located. Small juveniles of these species were also located in a small area just north of Port Gentil. As for the pelagic resources, the demersal registrations were very poor. In the area from Pointe Noire to Sette Cama the bigeye grunt (Brachydeuterus auritus) and croakers (Pseudotholithes spp.) dominated the shallow waters, while the seabreams (Dentex spp., Sparus spp., and Pagellus bellottii) and groupers (Epinephelus aenus) dominated the outer shelf. North of Cape Lopez in deeper waters the bigeye (Priacanthus arenatus) was common.

Rounded figures of the estimated biomass from the two surveys are:(thousand tonnes):

	Congo			Gabon			Both		
	Pel	Dem	Tot	Pel	Dem	Tot	Pel	Dem	Tot
Survey 2-15 March	30	5	35	70	25	95	100	30	130
Survey 30 may- 12 June	50	10	60	40	25	65	90	35	125

A moderate increase in the biomass of small pelagic fish has taken place in Congo. This could be fish migrating in from Cabinda or from north from Gabon. The unsurveyed oil drilling area south of Cape Lopez makes it difficult to see if variations in biomass in Gabon are due to growth/mortality causes or due to migration in/out of the restricted area.

As a general picture the resources for Gabon-Congo seems relatively constant in the period between the two surveys. Any major migration of pelagic fish from south had not taken place. It is likely that a migration will be monitored during the next coverage, in September.

As already mentioned above the demersal resources are likely underestimated by the acoustic method, and the swept area method is more reliable for assessing the demersal fish. During the last survey 43 semi-random trawl stations were carried out. From this a biomass of 160 thousand tonnes were estimated while the corresponding figures from the March survey was 125 thousand tonnes. During the last survey one extraordinary big catch raised the mean and the variance of the data series considerably. We therefore again assume that no real changes has taken place in the biomass since the first survey.

Records of fishing stations and catch of dominant species are shown in Appendix II.

APPENDIX I

INSTRUMENTS AND FISHING GEAR USED

Acoustic instruments

SIMRAD echo sounder EK 400, 38 kHz was used during the survey for estimation of fish density.

Instrument settings:

	EK400/38
Range	0-100 m
Transmitter	High (5000 W nom.)
Bandwidth	3.3 kHz
Pulse length	1 ms
TVG	20 log R
Attenuator	20 dB
Recorder gain	7
Transducer	Ceramic ($8^{\circ} \times 8^{\circ}$)

EK 400/38 was coupled to the digital integrator QD and to one analog integrator QM.

QD settings:	Gain	30 dB
	Threshold	25 mV
QM settings:	Gain	20 dB x 10
	Threshold	10

An ST sonar was used to detect fish schools close to the surface. Recorder range: 0-250 m.

Calibration on standard target (Baia dos Tigres, 28.4.1985)

EK 400/38 : SL + VR = 140.8 dB (Cu 60)

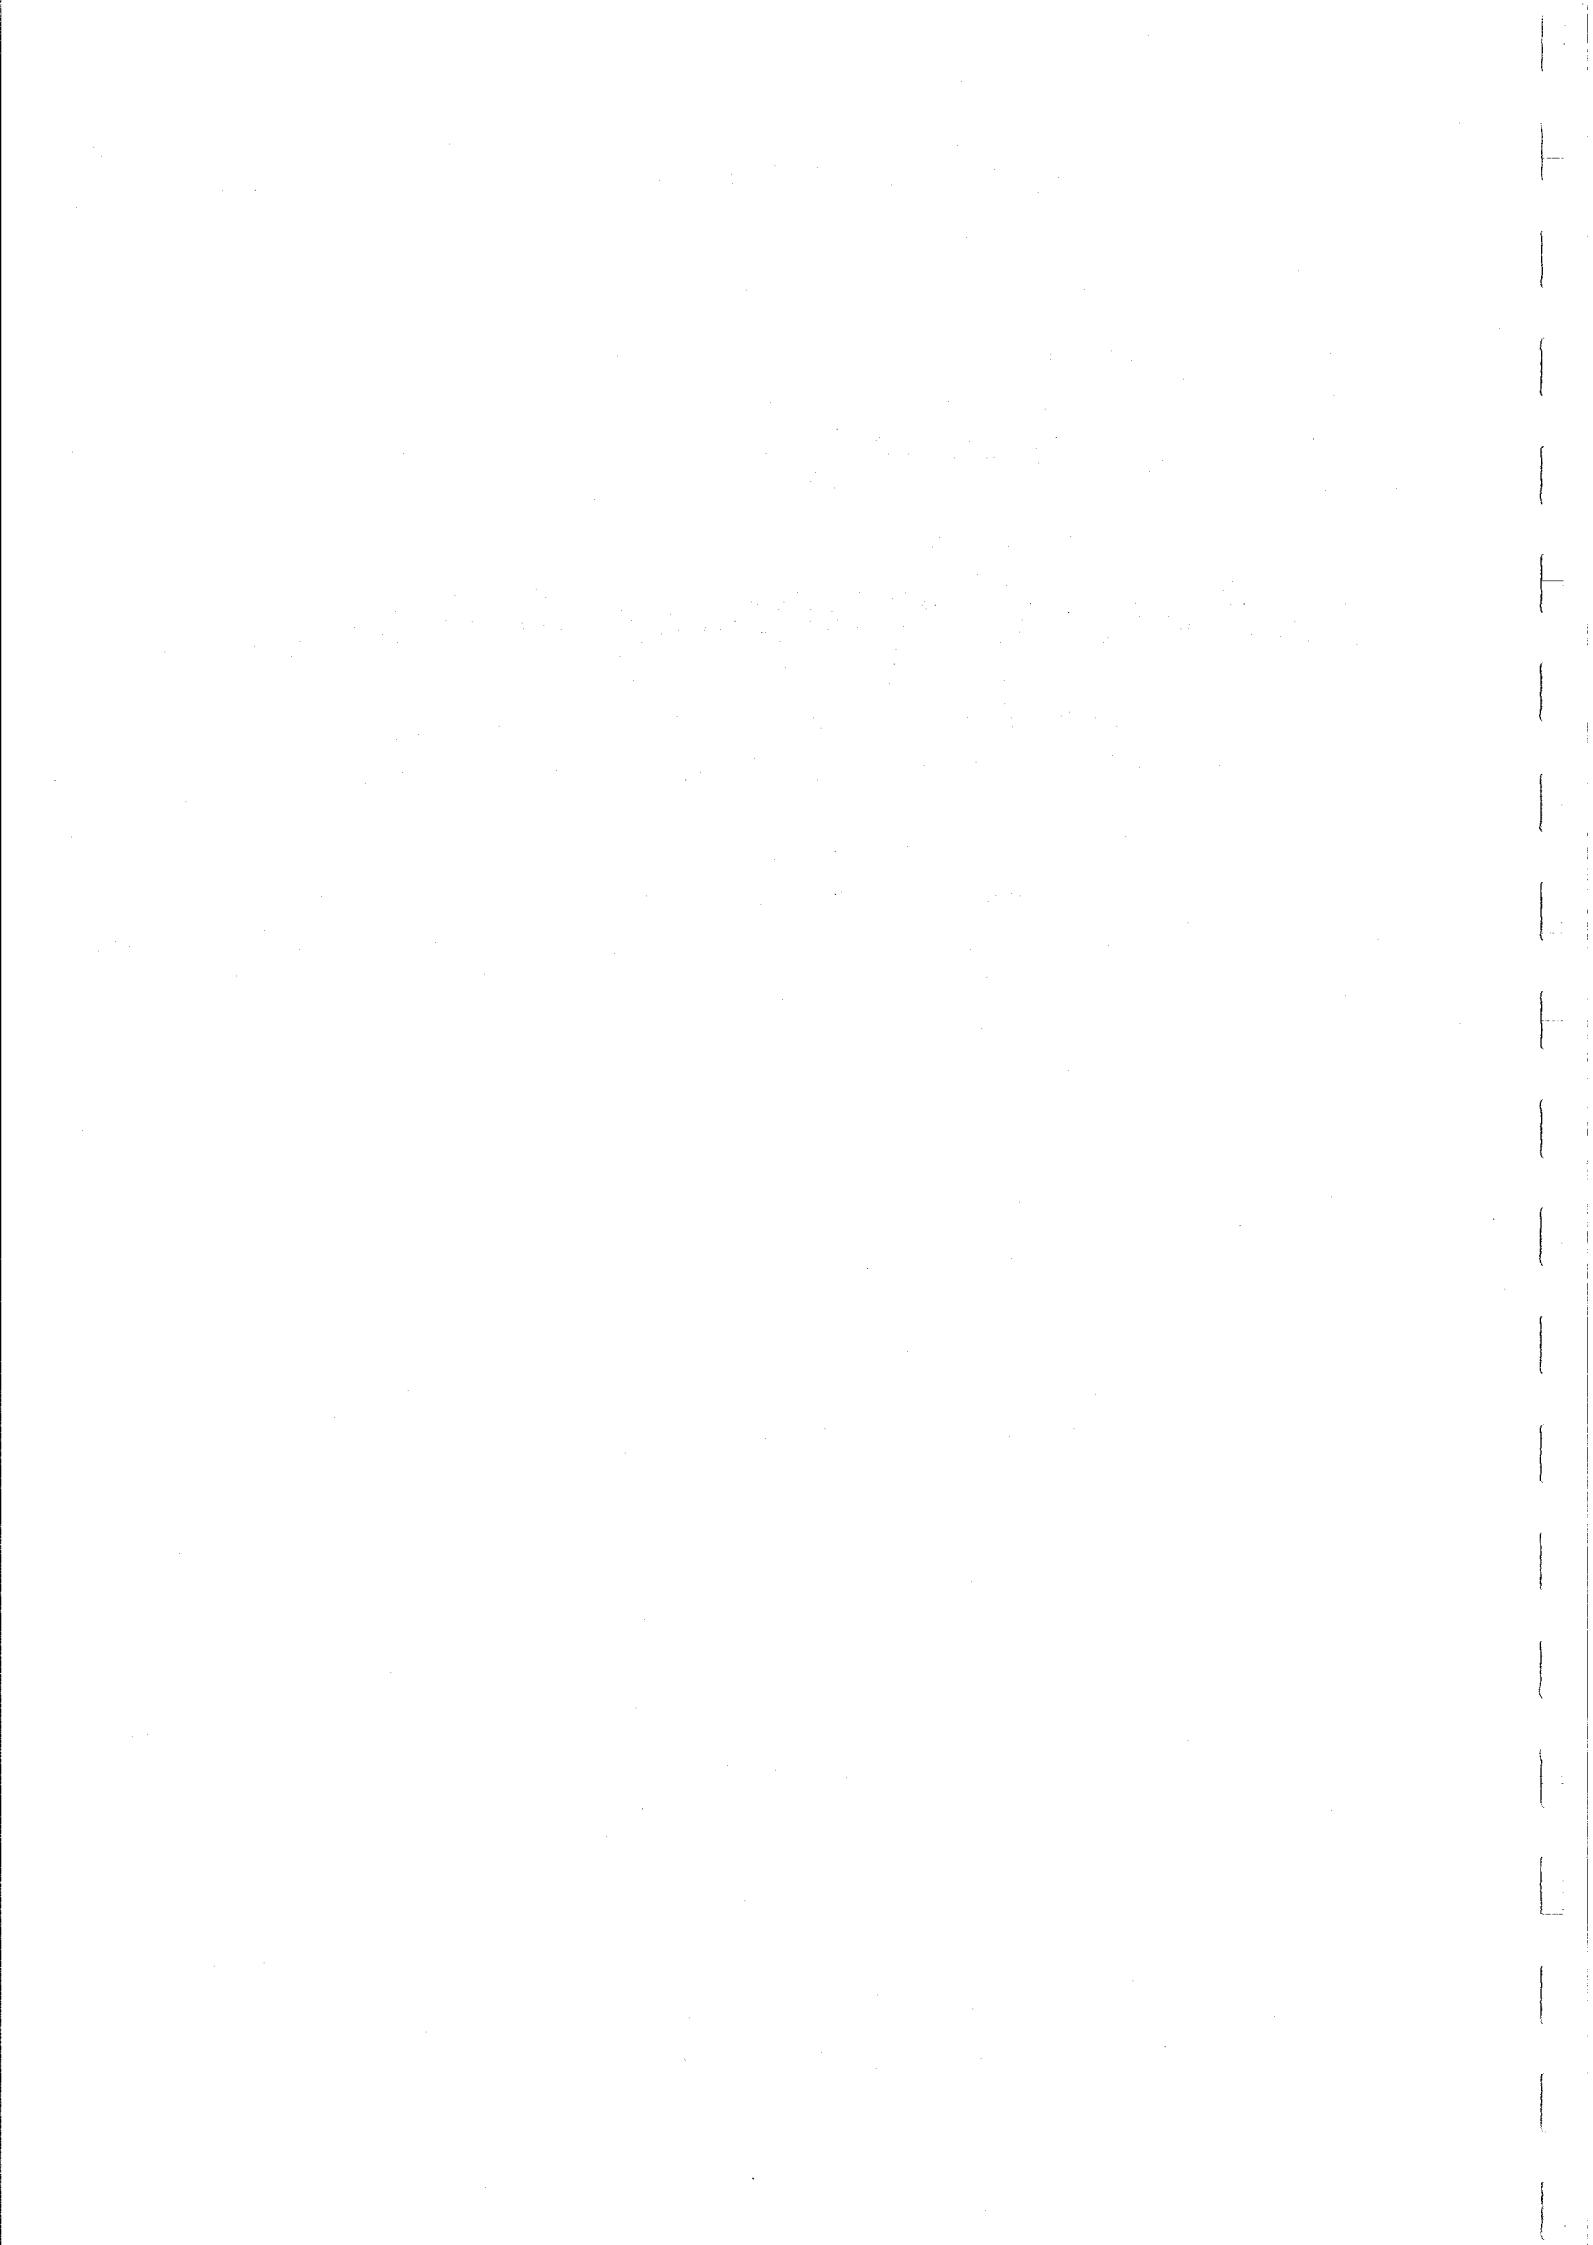

Hydrography

Temperature, salinity and oxygen content were sampled at standard depths with Nansen bottles. Oxygen was measured with the Winkler method and salinity determined with an inductive salinometer. Surface temperature was recorded at 4 m depth with thermograph.

Fishing gear

Bottom trawl: High opening shrimp and fish trawl with rubber bobbins gear, headline 31 m, headline height during trawling about 6 m.

Pelagic trawls: Type "Harstadtrawl", width about 30 m, vertical opening 14-16 m. Type modified "Bastrawl", width about 25 m, vertical opening about 25 m. All trawls with fine meshed inner lining in cod ends.

APPENDIX II

Record of fishing stations with dominant species.

BT: Bottom trawl

PT: Pelagic trawl
