## CHAPTER 1 INTRODUCTION

---

### 1.1 Objectives

The objectives of the survey had been previously agreed upon with the Director of the Instituto de Investigação Pesqueira (IIP). These can be summarized as follows:

- To map the distribution and estimate the abundance of the commercially important pelagic and semi-pelagic fish species in Angolan waters, north of Benguela, including the two sardinella species *Sardinella aurita* and *S. maderensis*, the Cunene horse mackerel *Trachurus trecae* and other pelagic species, mainly carangids.
- To estimate the biological condition of sardinella and Cunene horse mackerel, length weight relationships and reproductive stages.
- Describe the distribution, composition and abundance of major demersal species, with special emphasis on sea breams (Sparidae), Benguela hake (*Merluccius polli*) and deep-water shrimps (*Parapenaeus longirostris* and *Aristeus varidens*), from Cabinda to Benguela by a swept-area trawl programme.
- Perform comparative trawling with RV 'Goa' on the shelf.
- Collect stomach samples of Benguela hake for later quantitative laboratory analysis of the contents, with special emphasis on economically important shrimps (this study will be carried out by an Angolan student now participating in a M. Phil. course at the University of Bergen).
- Map the general hydrographic regime by using a CTD-sonde on all trawl stations all over the survey area and monitor the temperature, salt and oxygen on IIP standard profiles for hydrographical studies.
- Conduct current measurements with current meter mooring and ADCP system.
- On-the-job training for the Angolan participants on the main survey routines would be imparted, including collection and processing of raw data, species identification, utilization of the programme package NAN-SIS and general methodology in oceanographic research.

The northern region, from Cabinda to Luanda, would be covered by a combined acoustic and bottom trawl survey, since low concentrations of pelagic fish are expected at this time of the year in the northern region. The central area, from Luanda to Benguela would be covered twice, by an acoustic coverage (Luanda-Benguela) and by a demersal survey (Benguela-Luanda) of the shelf and of the upper slope.

## 1.2 Participation

The scientific staff consisted of:

From IIP, Angola:

Geraldina Assunçaõ, Bomba Bazica, António Buco, Lourenço Constança, Ana de Sousa, Pedro Panzo, Domingos Pedro (from 26 February to 9 March); Isabel Araújo, Tomatima Bengui, Manuel Domingos, Kumbi Kilombo, Eusébio dos Santos, Agostinho Duarte, Fernando Gombo, Filomena Vas Valho (from 11 March to 2 April).

From IMR, Bergen:

Oddgeir Alvheim (from 26 February to 24 March), Jarle Kristiansen, Bjarte Kvingle, Diana Zaera (from 26 February to 2 April); Guillermo Burgos (from 26 February to 9 March); Gabriella Bianchi and Tor Gammelsrød (from 11 March to 2 April).

## 1.3 Narrative

The vessel left Luanda in the morning of 26 February and steamed northwards to Cabinda. The sampling programme commenced north of the Congo River outside the closed oil-drilling area with course tracks approximately 20 nm apart, covering the inner, middle and the outer shelf and the slope to 800 m depth. Semi-random swept-area hauls were carried out on the shelf during daytime and on the slope deeper than 400 m during dark hours. CTD-stations were taken at almost all trawl stations. The standard profiles (Cabinda, Pta. da Moita Seca and N'Zeto) coincided with the corresponding survey transects. When shoals of pelagic fish were observed, the distance between the transects was decreased to obtain a better coverage. On 4 March we met RV 'Goa' near N'Zeto in order to perform comparative trawling. Unfortunately these trials had to be disrupted due to breakdown of a generator onboard the RV 'Goa'.

The vessel called at Luanda on 9 March for change of crew. On 11 March the second part of the survey started with an acoustic coverage of the pelagic resources between Luanda and Benguela. The course track consisted of systematic triangular transects, their endpoints about 10 nautical miles apart. This distance was however smaller (to about 5 nautical miles) in correspondence with narrower parts of the shelf. In areas where high concentrations of pelagic fish were detected, surveying was conducted both during daytime and nighttime. CTD (Conductivity-Temperature-Depth) and ADCP (Acoustic Doppler Current Profiler) measurements were taken at every trawl station. From 18 to 19 March, a current meter mooring was deployed at 11° 44' S and 13° 26' E.

The pelagic survey terminated on 21 March off Benguela where the second coverage of the shelf and upper slope area of the central region started the same day. The course track was changed to transects perpendicular to the coast, about 15 nautical miles apart, running from about 20 to 800 m depth. A call was made in Lobito to disembark a member of the Norwegian crew on March 24. The survey was resumed immediately and ended on 2 April with the arrival in Luanda.

#### 1.4 Survey effort

Figures 1a-c show the cruise tracks with fishing stations and the hydrographic profiles and Table 1 the number of hydrographic, pelagic and bottom trawl stations, successful swept-area hauls by area and depth interval.

Table 1 Number of hydrographic (CTD), pelagic (PT), bottom (BT) trawl stations, successful swept-area hauls and distance surveyed (nm) by area.

Area	CTD	PT	BT	Swept-area hauls			Distance surveyed
				0-200m	200-400m	400-800m	
Cabinda-Luanda	78	10	77	37	19	19	1 400
Luanda-Benguela	65	40	7	—	—	—	1 620

## CHAPTER 2 METHODS

---

### 2.1 Hydrographic sampling

A Seabird 911 CTD plus was used to obtain vertical profiles of temperature, salinity and oxygen. Real time plotting and logging was done using the Seabird Seasave software installed on a PC. The profiles were taken down to a few metres above the bottom. Two Niskin bottles were triggered for water samples on each station, one near the bottom and one near the surface (3 m depth). The samples were analysed for salinity using a Guildline Portasal salinometer, and the oxygen content was determined using the Winkler method. These laboratory values were used for calibration of the CTD after removing obvious outliers.

Using 173 points for the salinity calibration a standard error of 0.029 resulted, without any adjustment of the CTD values. This was accepted. It should be noted that a better calibration may be obtained using only the bottom samples, where the gradients in T and S are usually smaller.

For oxygen 64 samples were accepted for the calibration. A linear regression gave the following formula for correcting the oxygen values:

$$O_f = O_{2ctd} * 1.329 + 0.207$$

Applying this formula a standard error of 0.141 was obtained.

### *Current meter mooring*

A current meter rig consisting of 3 Aanderaa RCM7 current metres and a WLR8 pressure gauge was deployed for about 24 hours. Each current meter was equipped with pressure, temperature and conductivity sensors, thus allowing to calculate salinity. Furthermore, they also included a data Storing Unit, where data were stored with a 10 min. interval. The Data Storing Units were read by a DSU reader using a PC and the P3059 software supplied by Aanderaa Instruments.

### *ADCP current measurements*

A ship born Acoustic Doppler Current Profiler (ADCP) from RD Instruments was activated on every trawl and CTD station where bottom tracking was obtained, i.e. bottom depths less than about 400 m. The ADCP was set to ping every 8 seconds, the depth cell was chosen to 8 m and the number of cells to 50. As a routine the data were averaged over 300 seconds for analyses onboard. Both the raw and averaged data were stored on files. The data were analysed by the PC software UMS (Underway Mapping System), supported by the Sea Fisheries Research Institute, Cape Town, South Africa (Zauner, 1993).

### *Meteorological observations*

Wind (direction and speed), air temperature, global radiation and sea surface temperature (5 m depth) were logged automatically every nautical mile using an Aanderaa meteorological station.

### *Observations of internal waves*

The echograms from the acoustic instruments for fish sampling were occasionally used to identify internal waves. Simultaneously CTD stations and visual observations of surface slicks were performed, such that the characteristics of the waves could be identified and compared with the theory.

## **2.2 Fish sampling**

### 2.2.1 Acoustic survey

#### *Abundance estimation*

The catches were sampled for species composition, by weight and numbers. Biological samples, i.e. length and weight compositions were taken for the target species. Records of fishing stations are presented in Annex I.

A description of the acoustic instruments and their standard settings is given in Annex II. This also includes a description of the fishing gear used.

The following target strength (TS) function was applied to convert  $S_A$ -values (mean integrator value for a given area) to number of fish (pilchard, sardinella and Cunene horse mackerel):

$$TS = 20 \log L - 72 \text{ dB} \quad (1)$$

or in the form  $C_F = 1.26 \cdot 10^6 \cdot L^{-2}$  (2)

where  $L$  is total length and  $C_F$  is the fish conversion factor. The following formula was used to calculate the number of fish in length groups (cm) for each fish concentration:

$$N_i = A \cdot S_A \cdot \frac{p_i}{\sum_{i=1}^n \frac{p_i}{C_{Fi}}} \quad (3)$$

where

- $N_i$  = number of fish in length group i
- $A$  = area (naut.miles<sup>2</sup>) of fish concentration
- $S_A$  = mean integrator value in area (A)
- $p_i$  = proportion of fish in length group i in samples from the area
- $C_{fi}$  = fish conversion factor for length group i

The number per length group ( $N_i$ ) was then summed and the total number of fish obtained:

$$N = \sum_{i=1}^n N_i \quad (4)$$

The length distribution of a given species within an area was computed by weighting the length frequencies obtained in each trawl sample within the area by the average  $S_A$  value attributed to that species in the 5 mile where the sample was taken.

In the case of cooccurrence of *Sardinella aurita* and *S. maderensis* (these species cannot be separated in the echo traces), the respective contribution to the  $S_A$  value attributed to the 'sardinella' category was split using a factor obtained from their length frequency distributions and their CPUE in numbers. The biomass of fish per length group ( $B_i$ ) was calculated by applying observed mean weights per length group ( $W_i$ ) multiplied by number of fish in the same length

groups ( $N_i$ ). The total biomass in each area was obtained by summing the biomass of each length group:

$$B = \sum_{i=1}^n N_i \bar{W}_i \quad (5)$$

The number and biomass per length group in each concentration were at last summed to obtain the totals for each region.

The mean integrator values in each sampling unit ( $S_A$ -values) were divided between the following categories of fish on the basis of trawl catches and characteristics of the echo traces:

- sardinella (*S. aurita* and *S. maderensis*)
- Cunene horse mackerel
- P2 (carangids, scombrids, barracudas and hairtails)
- Big eye grunt (*Brachydeuterus auritus*)
- other demersal fish
- plankton

#### *Biological sampling*

Total length and body weight were recorded for sardinella and horse mackerel to the nearest  $\frac{1}{2}$  cm or 1 g below, respectively. Sex and reproductive stages were described by macroscopic examination, scoring each individually sampled fish according to the following categories:

- |   |               |
|---|---------------|
| 1 | Juvenile      |
| 2 | Inactive      |
| 3 | Active        |
| 4 | Ripe          |
| 5 | Running/Spent |

Table 2 Areas used in the swept-area biomass estimates ( $\text{nm}^2$ ).

Depth stratum (m)	Cabinda-Luanda	Luanda-Benguela
0-50	3 023	1 850
50-100	2 693	1 730
100-200	2 085	1 252
200-300	755	500
300-400	660	350
400-500	540	445
500-600	880	450
600-800	1 500	900

#### 2.2.2 Bottom trawl survey

The catches were sampled for species composition by weight and numbers. Length distributions (total length for fish and carapace length for shrimp) were taken for the main species. Biological samples, i.e. length weight, sex and maturity stages, were taken for Benguela hake in connection with stomach

sampling. The records of fishing stations are presented in Annex I. Pooled length frequency distributions (weighted by the catch) of selected species by area, are shown in Annex II. Table 2 shows the areas used in the swept-area biomass estimates.

A stratified random design was used, with depth and main geographic regions (northern and central areas) as stratifying variables. The allocation of trawl stations was approximately proportional to the stratum size. Biomass estimates by species were obtained by summing the estimates calculated for each depth stratum. Confidence intervals were calculated for deep-water shrimp species only. For these species, the stratified variance was calculated as:

$$Var(\bar{y}_{st}) \approx \sum_{h=1}^L W_h^2 \left( \frac{s_h^2}{n_h^2} \right) \quad \text{where:} \quad W_h = \frac{A_h}{A}$$

where  $n_h$  is the number of hauls in stratum  $h$ ,  $s_h^2$  is the sample variance in stratum  $h$ ,  $W_h$  is the stratum weight for stratum  $h$  (ratio between area of stratum  $h$  ( $A_h$ ) to the total survey area ( $A$ )) and  $L$  is the total number of strata.

The bottom trawl has a headline of 31m (float line), footrope 47 m, estimated headline height 5 m and distance between wings during towing about 18 m. During trawling a 9.5 m long rope was fastened between the wires 150 m in front of the doors giving a constant distance between the doors of 49-50 m. All trawl hauls were monitored by SCANMAR trawl sensors (bottom contact, headline height and distance between the doors) and the actual time the trawl was fishing on the bottom was determined with improved accuracy. For conversion of catch rates to fish densities the area between the wings is assumed to be the effective fishing area i.e. the catch ability coefficient  $q$  is equal to 1. The footrope was equipped with a tickler chain which improves the catch ability of bottom living and borrowing species.

A more detailed description of the fishing gear, the acoustic instruments and their standard settings is given in Annex IV.

## CHAPTER 3 OCEANOGRAPHIC CONDITIONS

---

Anomalous oceanographic conditions were found along the whole Angolan coast. The upper 10 to 50 m were dominated by a warm ( $T \sim 29^{\circ}\text{C}$ ) and brackish ( $S \sim 30\text{psu}$ ) water mass. The static stability in the surface layer was therefore very high, and put an effective lid on top of the water column, thus inhibiting vertical circulation and upward transports of nutrients. The present situation is therefore not favourable for biological production and may have a detrimental effect on pelagic fish. It has happened before that the surface layers in Angolan waters have been dominated by a warm and brackish water mass. However, conditions as extreme as observed on the present cruise have, to our knowledge, never been observed before. There is no doubt that this situation will be much discussed in the future, and might be recorded as "The 1995 Benguela el Niño".

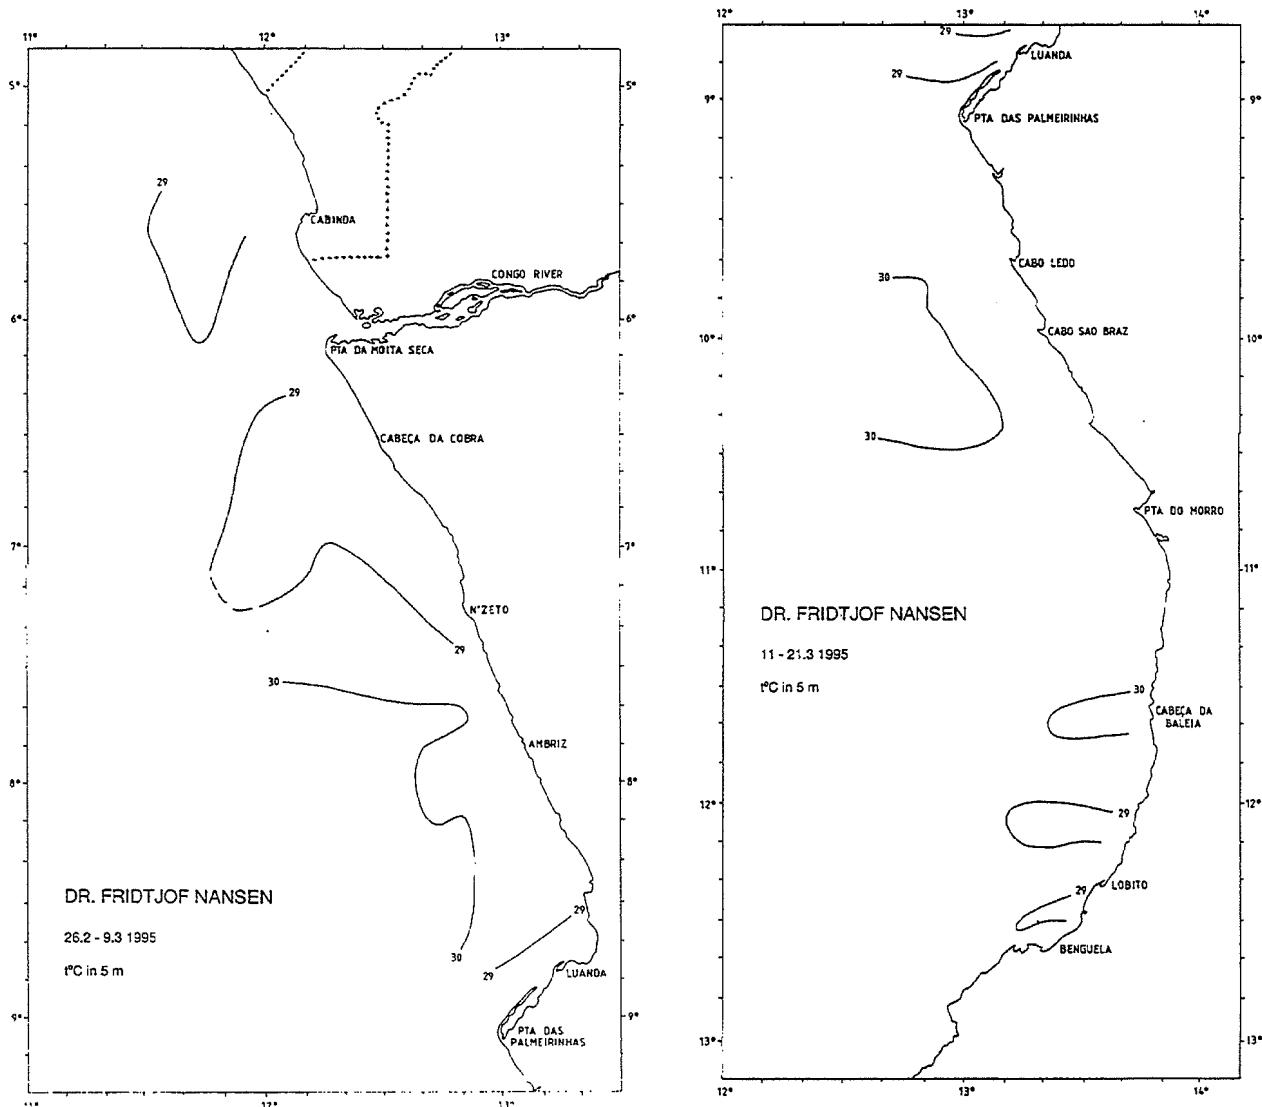

Figure 2 Horizontal distribution of surface (5m) temperature. Cabinda-Luanda and Luanda-Benguela.

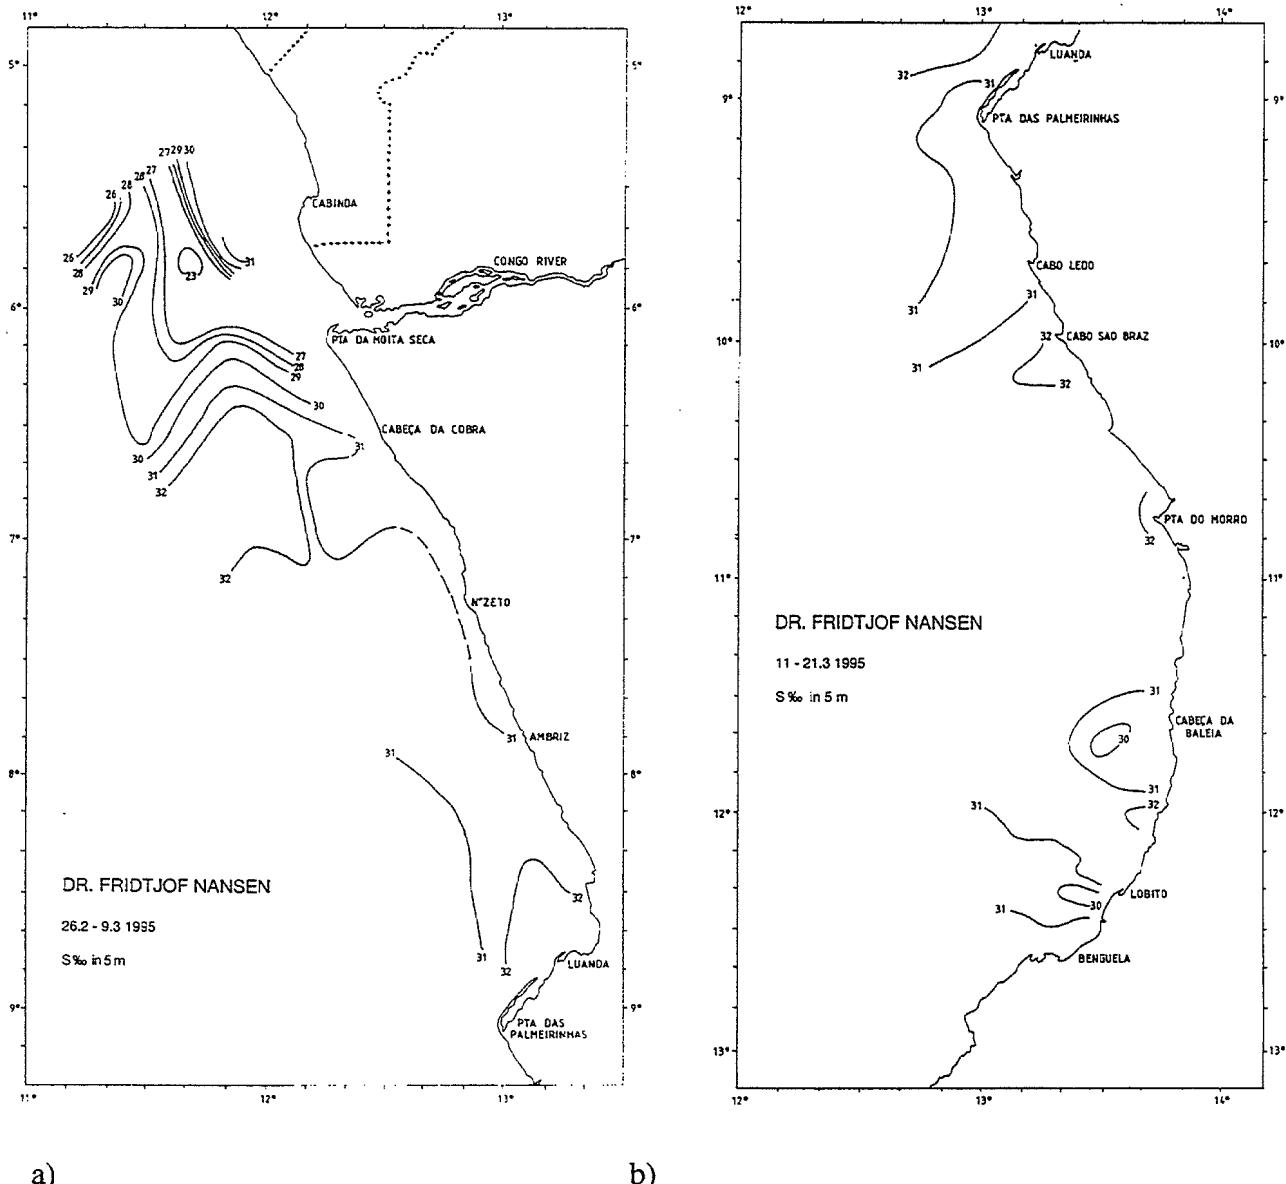

Figure 3 Horizontal distribution of surface (5m) salinity. Cabinda-Luanda and Luanda-Benguela.

#### Surface distribution

The temperature at the surface (5 m depth) is shown in Fig 2 (a and b), and the salinity distribution in Fig. 3 (a and B). Note the flat structure of the temperature distribution with temperatures between 29 °C and 30°C. The salinity distribution is also flat except for the obvious influence from the Congo River. Usually there is a weak upwelling along the coast at this time of the year evidenced by lower temperatures or higher salinities adjacent to the coast. These conditions were never observed in the course of this survey.

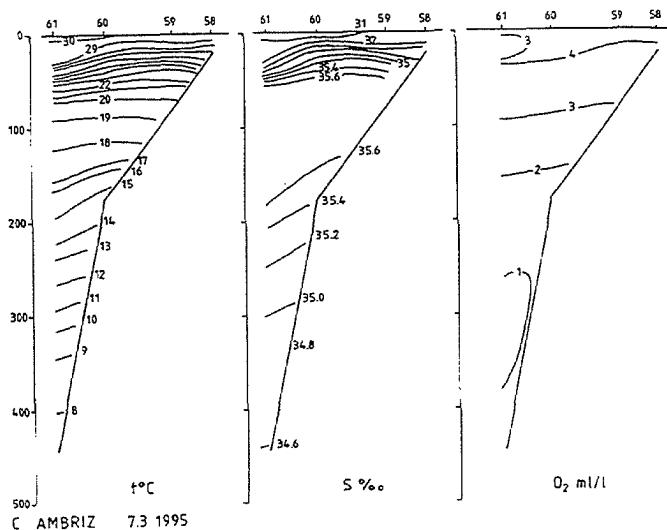

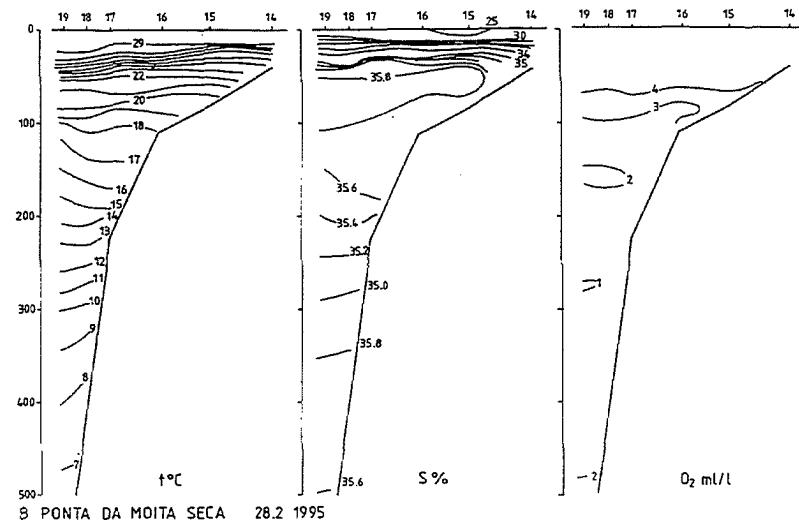

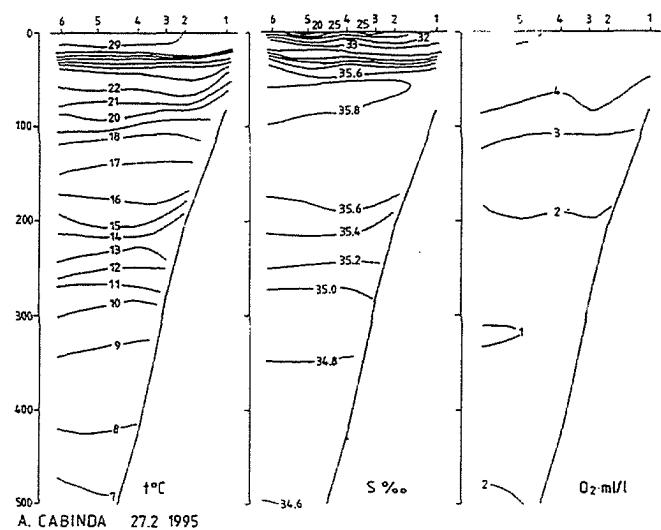

Figure 4 Vertical sections of temperature, salinity and oxygen.

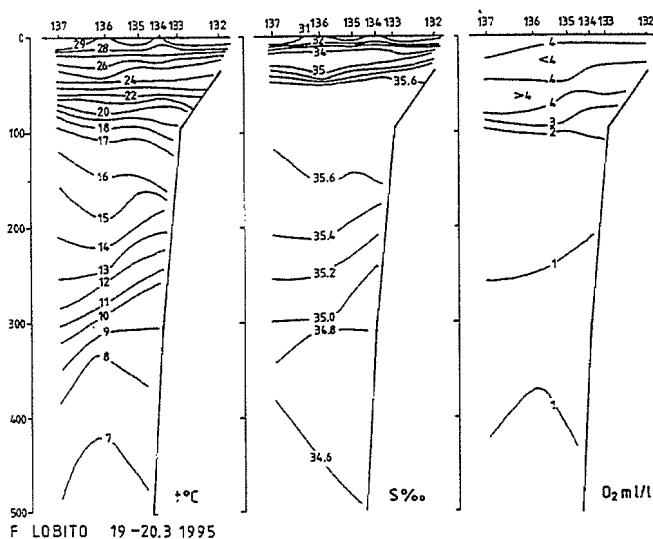

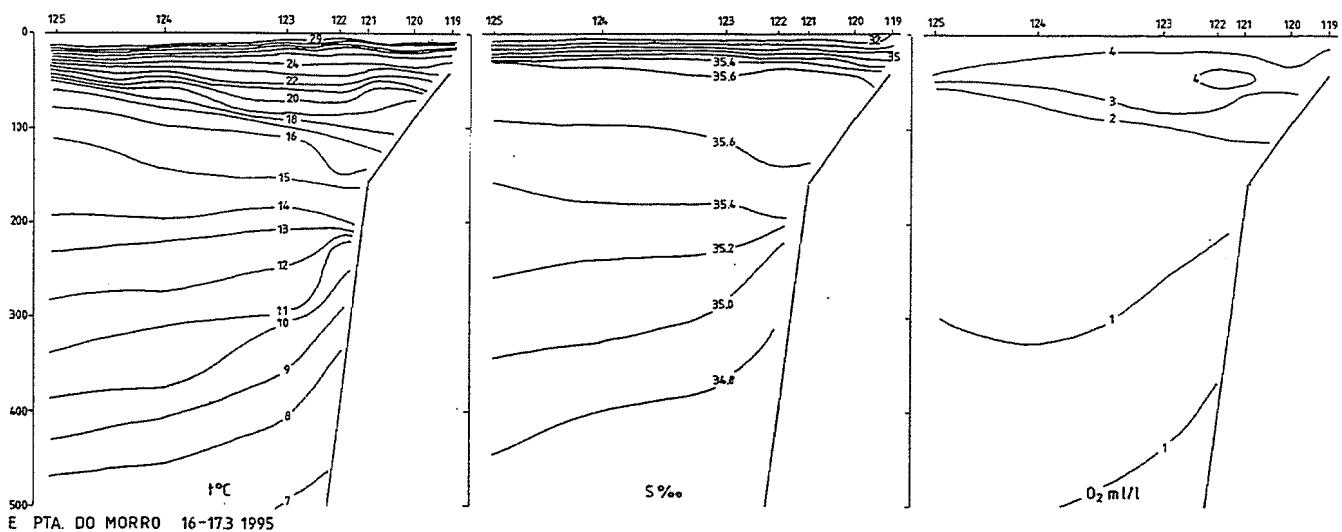

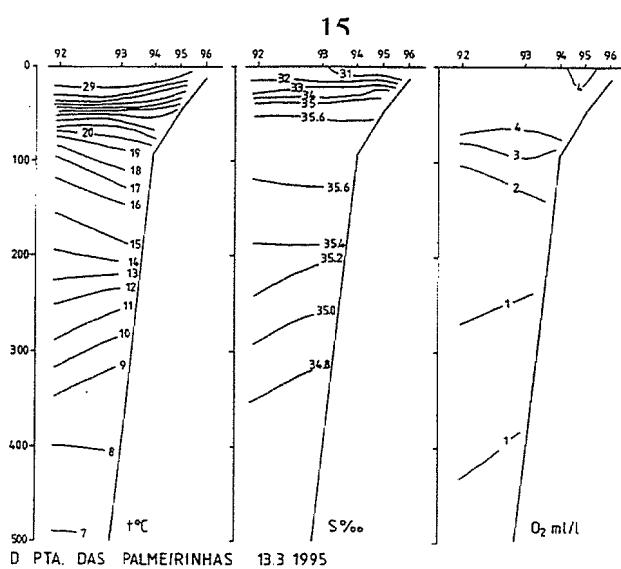

Figure 4 (cont.) Vertical sections of temperature, salinity and oxygen.

### *Vertical sections*

The vertical distributions of temperature, salinity and oxygen along the standard sections are shown in Figures 4 a-e. The most striking feature is the warm and fresh upper layer all the way south to Lobito. The thermocline and halocline are found between 25 and 50 m. We prolonged the sections at Pta.. do Morro (Fig. 4) and Ponta das Palmeirinhas to more than 100 nautical miles from the coast, and even here the fresh, warm layer dominated. Thus we have not been able to map neither the western nor the southern limits of this extreme water mass.

The oxygen distribution is more or less as usually observed, but the surface layer seems to be a little depleted in oxygen, especially in the southern part (Pta.. das Palmeirinhas and southwards) were the oxygen concentration is usually about 1 ml/l higher.

### *Comparison with last year situation*

To illustrate how different the present situation is from the normal condition, we have compared CTD station 93 in the Pta. da Palmeirinhas section (see map Fig.1) obtained at about 200m depth with a corresponding station last year, which was quite "normal". The results are shown in Fig. 5. We note the upper 100 m are dominated by warmer water in 1995, with a maximum difference of more than 8°C between 25 and 35 m depth. Taken into consideration the vast area influenced by this warm water, this is a significant climate signal as the increase of 8°C over a 10m water column corresponds to a heating of the whole atmospheric column of more than 30°C!

Above 50 m depth the salinity difference starts to become noticeable, and the maximum difference of about 4 psu is found in the surface layer. The excess fresh water content may be calculated as follows.

Assuming that an amount of fresh water ( $\Delta h$ ) is distributed over a water column H, the salinity balance equation reads:

$$\int_{-H}^0 \rho_{94} S_{94}(z) dz = \int_{-H}^{\Delta h} \rho_{95} S_{95}(z) dz$$

where  $\rho$  is the density and S is salinity, indexes indicate years. Neglecting the variation in the density and splitting up the integral on the right hand side and re-arranging gives the following expression for the increase in fresh water content (precipitation) in the water column:

$$\Delta h = \frac{1}{S_{95}(0)} \int_{-H}^0 S_{94}(z) - S_{95}(z) dz$$

where  $S_{95}(0)$  is the surface salinity from the present cruise. A numerical integration of this equation down to depths where the salinity differences are small (at least 40m) gives an increase in the fresh water content corresponding to about 3000 mm precipitation. These conditions are comparable to those found in areas of the Gulf of Guinea characterized by similar average precipitation and surface salinities.

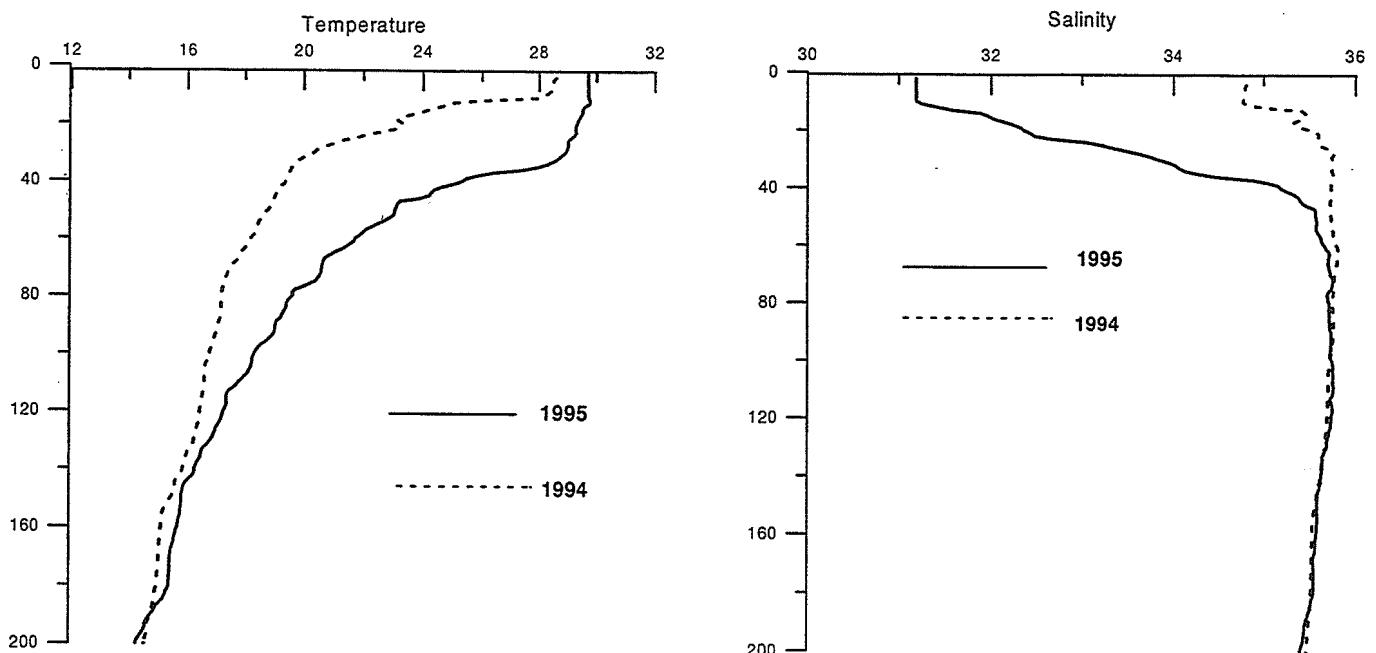

Figure 5 Temperature and salinity profiles from CTD st. 93 in the Ponta das Palmeirinhas section (see Figs 1 and 4), and the corresponding profiles from the March 1994 survey.

#### *Current measurements from an anchored mooring*

The current meter rig was anchored at 80 metres water depth outside Rio Eval in position 11°44'S, 13°26'E, (Fig.1). The registrations started the 18th of March and lasted for about 24 hours. The results are shown in Fig. 6. Full moon occurred on March 17th, so our observations are taken shortly after the spring tides. A semidiurnal tidal signal is clearly seen in the water level registration, and we note that the amplitude, which is about 1 meter, shows a decreasing tendency.

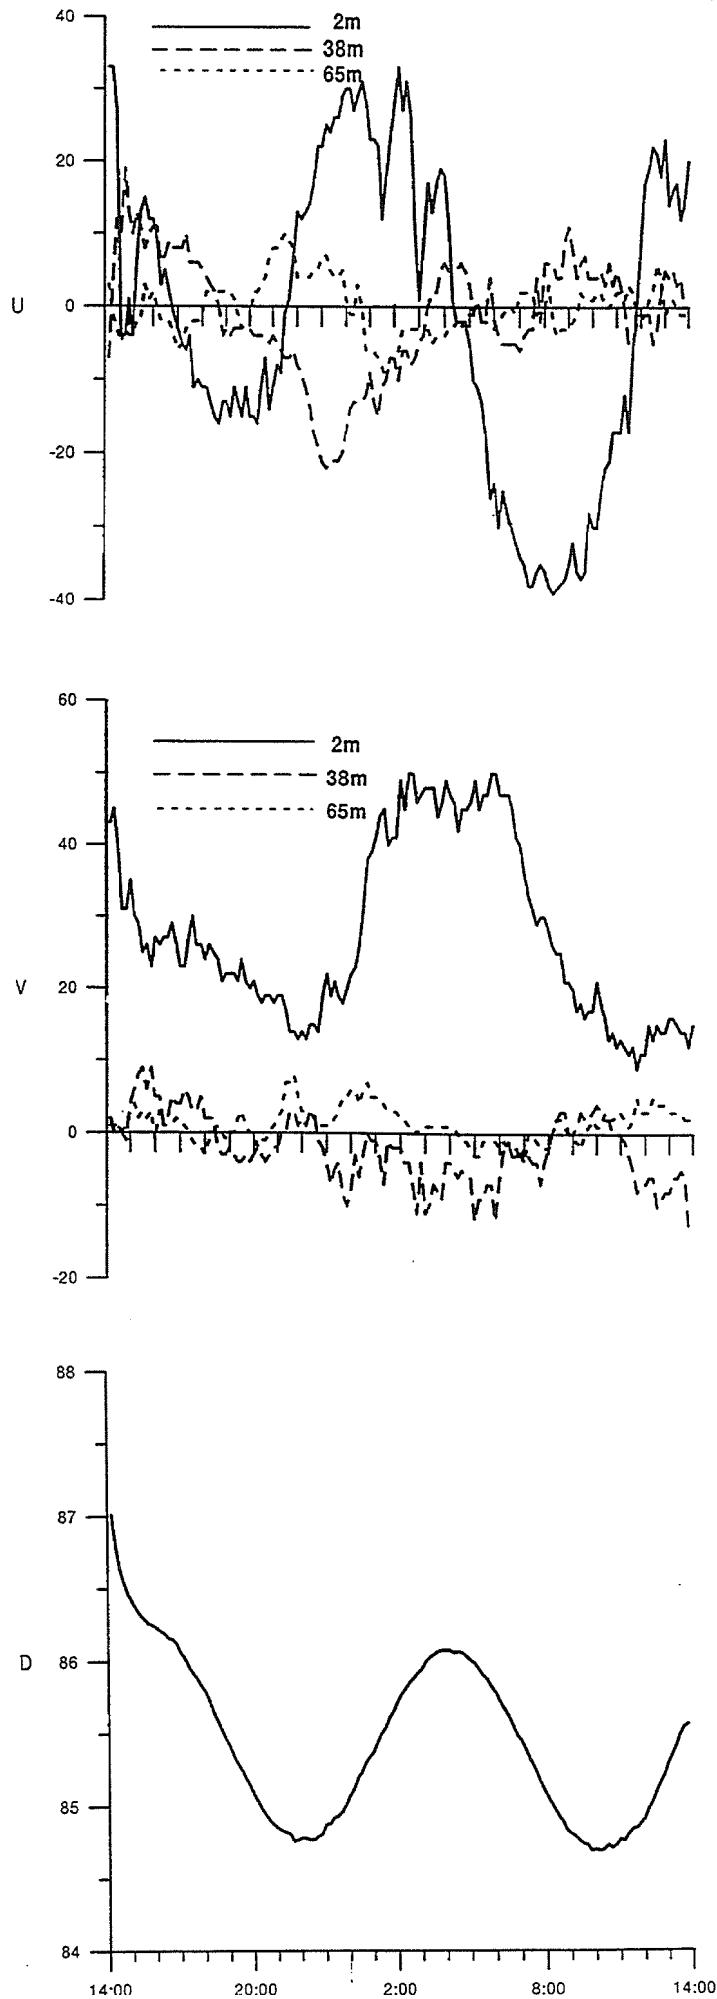

Figure 6 Current measurements at 2m, 38m and 65m obtained from the mooring. Upper panel: east component (U); central panel: north component (V), and lower panel: water level registrations in metres.

The currents are presented as easterly (U) and northerly (V) components at the various depths in Fig. 6. The current is much stronger in the surface layer (2 m) than deeper down (38 m and 65 m). The surface current is mainly northwards with a maximum current of about  $\frac{1}{2}$  m/s coinciding with high tide. The surface V-component is the only component which never crossed the zero line, its minimum value was about 0.1 m/s, which means that the brackish surface layer is moving steadily and rather fast northwards.

The tidal signal in the surface U component is about twice as big (amplitude 0.35 m/s) than in the V component, which means that the tidal ellipse probably has its main axis oriented perpendicular to the coast. In the deeper layers the currents are much weaker, and no conclusion can be drawn on average currents from such a short series. At 38 m depth the currents seem to be  $180^\circ$  out of phase with the surface current, while a higher frequency seems to dominate the bottom current.

#### *ADCP current registrations*

The Acoustic Doppler Current Profiler was activated on every trawl and CTD stations where bottom tracking was possible (less than about  $\sim 400$  m depth). As this instrument is rather new to us, and there is some doubt about the alignment of the transducers, we have chosen not to present the data yet. However, the general impression is a southbound flow at all levels below 35m with speeds up to  $\frac{1}{2}$  m/s. The signals are noisy, though, and further analysis and some smoothing should be performed before publishing these data.

#### *Internal waves*

Fig. 7 shows an echogram where the undulating signal from the phytoplankton in the halocline at about 20 m (see CTD station 190 inserted) is clearly seen. Simultaneously surface slicks were observed to move perpendicular to the ship heading coinciding with the wave crests at the echogram. Thus the frequency of the internal waves may be read directly from Fig. 7, and indicate a period (T) of about 5 min. As indicated on the echogram the ship was turning 90 degrees, speeding up and heading into the propagating waves. As the ship was moving with 9 knots and we now know the frequency of the waves, the wavelength ( $\lambda$ ) may be estimated from the last part of the echogram, which gives  $\lambda \sim 150$  metres. This indicates a phase speed  $C = \lambda/T$  of about 0.5 m/s. Assuming a two layer model, with a density difference of  $3 \text{ kg/m}^3$ , an upper layer of 20 m and a lower layer of 60 m, the reduced gravity model for internal waves yields a phase speed  $C = 0.54$  m/s, which is close to the observed estimate. Dedicated experiments should be set up to study these waves in detail, as they may play a significant role in upper layer mixing as they break, thus

transporting nutrients to the surface layer. This mechanism has been characterized in other part of the world ocean as a "nutrient pump at work".

#### *On-the-job training*

The Oceanographers, Fernando Gombo and Isabel Araujo took care of the water sampling from the CTD-rosette sampler. They analysed for Oxygen content using the Winkler method, and the salinity was determined using the Guildline Portasal Salinometer. The vertical sections and the horizontal distribution maps were mainly prepared by them.

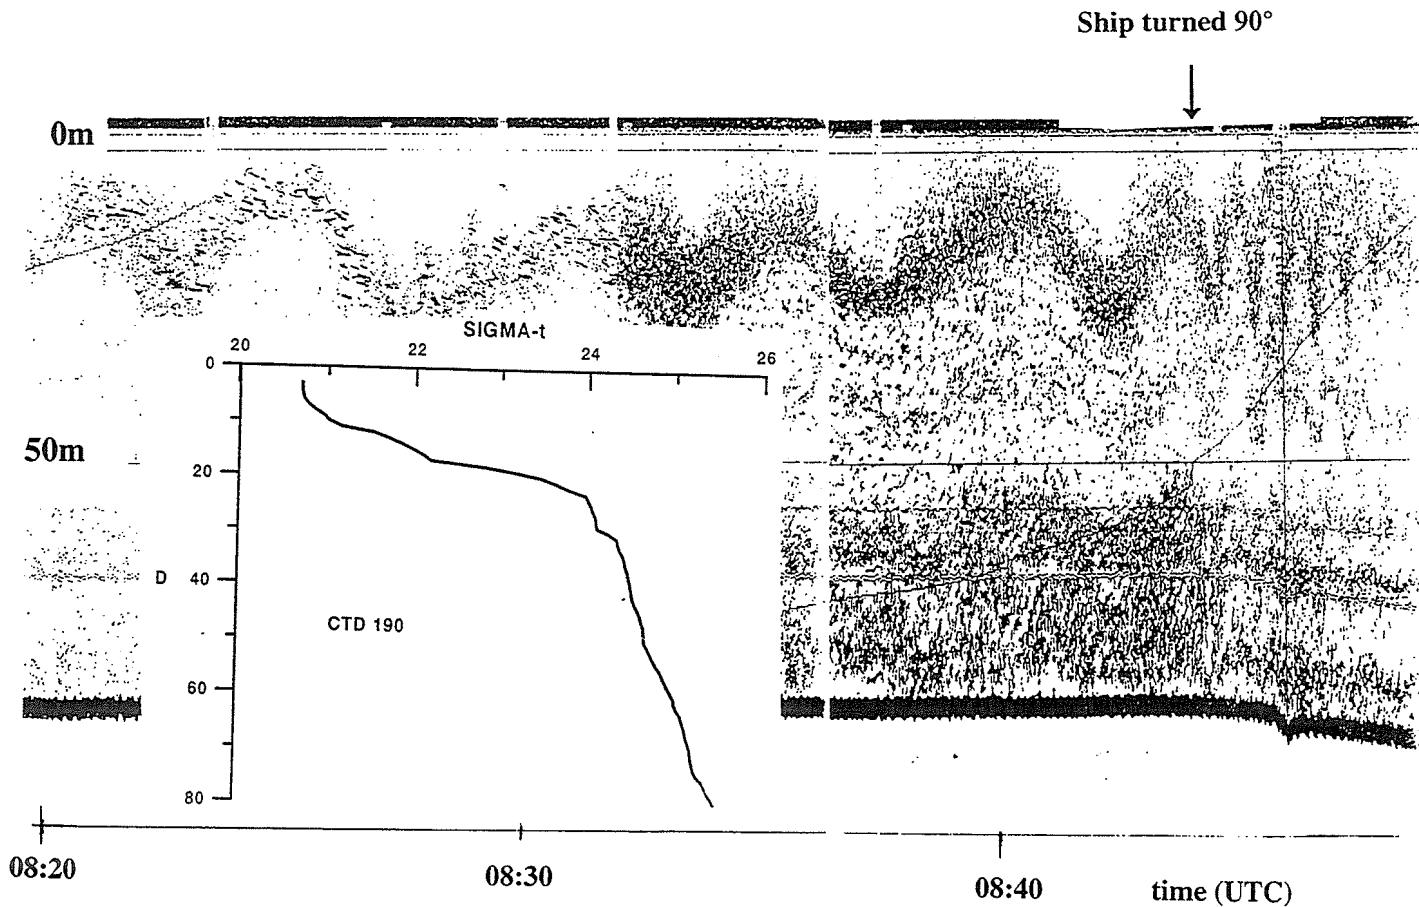

Figure 7 Echogram taken on March 30 at about 8:20 to 8:50 UTC in position 09°34 S 12°58 E. The undulating structure between 0 and 30 m is due to reflection from phytoplankton in the halocline. After about 20 minutes when the ship was moving parallel to the wave crests, the ship turned 90 degrees left heading into the waves. The corresponding shift in the frequency is clearly seen.

## CHAPTER 4 DISTRIBUTION, COMPOSITION AND BIOMASS ESTIMATES OF PELAGIC FISH

---

The acoustic coverage of the northern region (Cabinda-Luanda) was combined with the demersal survey because low densities of pelagic fish were expected there. According to the results obtained in previous surveys, there is in fact a tendency for pelagic fish (at least sardinella and horse mackerel) to move to the central part of the area (Luanda to Benguela) during the warm summer season. They become more abundant in the north in the course of the upwelling season (July to September). A double coverage was therefore planned for the central region, where higher concentrations of pelagic fish were expected at this time of the year. As in the March 1994 survey, the inshore area about 10 nm width north of Ambriz and the restricted area off Cabinda were not covered because of security reasons and oil extraction activities, respectively.

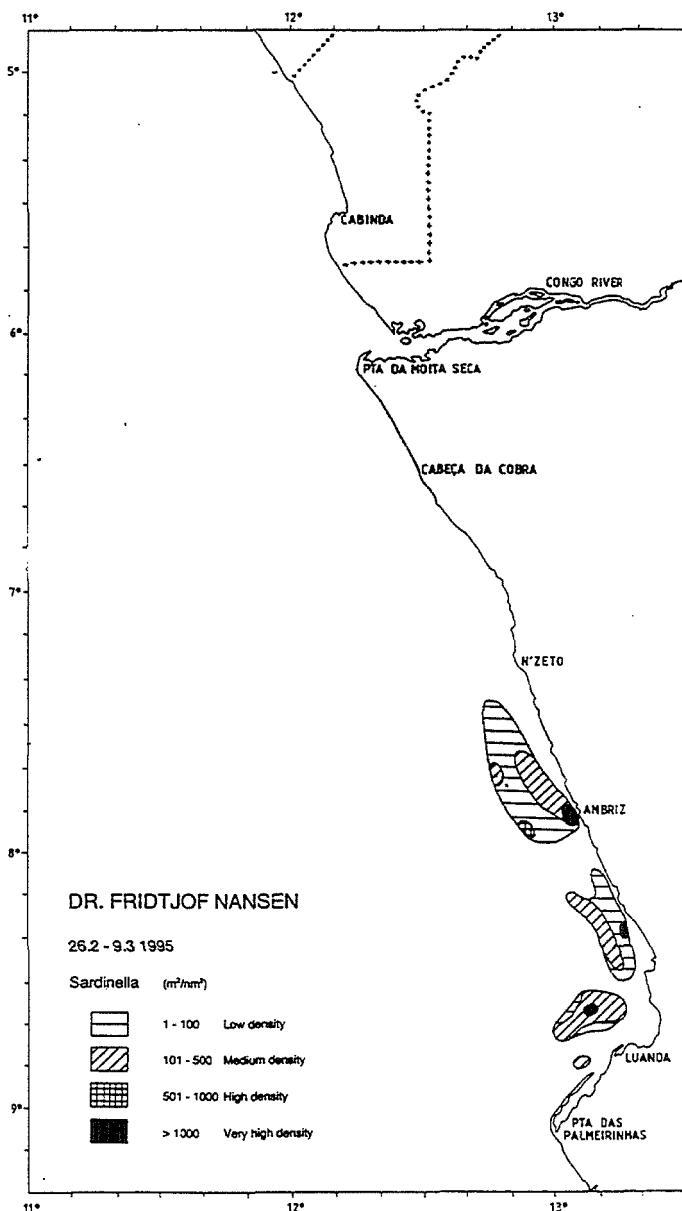

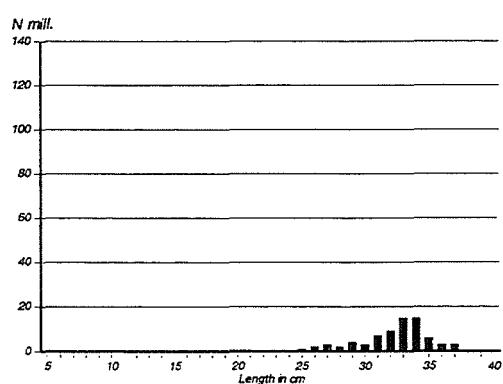

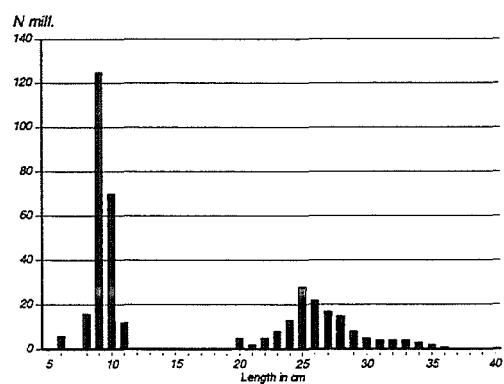

### 4.1 Cabinda-Luanda

#### 4.1.1 Sardinella

Figure 8 shows the distribution of both sardinellas in the northern region, including the varying degree of their concentrations as average acoustic integrator values for each area. *Sardinella* was detected in shelf waters south of N'Zeto to Luanda. *Sardinella maderensis* was more widespread, while *S. aurita* appeared mostly concentrated in a small but dense patch off Ambriz.

The length frequency distribution of *S. maderensis* shows the presence of three cohorts, of modal lengths of 9, 25 and 33 cm respectively (Fig. 9 a). Only large specimens of *S. aurita* were represented in the catches and the length frequency distribution showed a modal length of 34 cm (Fig. 9 b).

The biomass estimate for the two species combined totalled about 24 000 tonnes, divided between the two species in equal proportions.

Figure 8 Distribution of *Sardinella* spp. Cabinda-Luanda.

a)

b)

Figure 9 Total length distribution of a) flat sardinella (*Sardinella maderensis*) and b) round sardinella (*S. aurita*). Cabinda-Luanda.

#### 4.1.2 Cunene horse mackerel

Figure 10 shows the distribution of Cunene horse mackerel for the region Cabinda-Luanda. No acoustic recordings were attributed to this species in the northern part of this region. A small concentration was identified off Ambriz and estimated to 300 tonnes. It consisted of young specimens, with modal lengths of 14 and 19 cm. A second concentration was located off Luanda and evaluated to about 8 800 tonnes, consisting of very large specimens with modal length of 39 cm. The most important was however located just outside Luanda and to Pta. das Palmeirinhas, at depths of 100 to 150 m and estimated to 75 000 tonnes. This consisted mainly of large horse mackerel, with a modal length of 37 cm. Smaller cohorts were however also represented, with modal lengths of 14, 19 and 29 cm respectively. Figure 11 shows the length distribution of horse mackerel for the whole region. The total biomass of horse mackerel in this region was estimated to 84 000 tonnes.

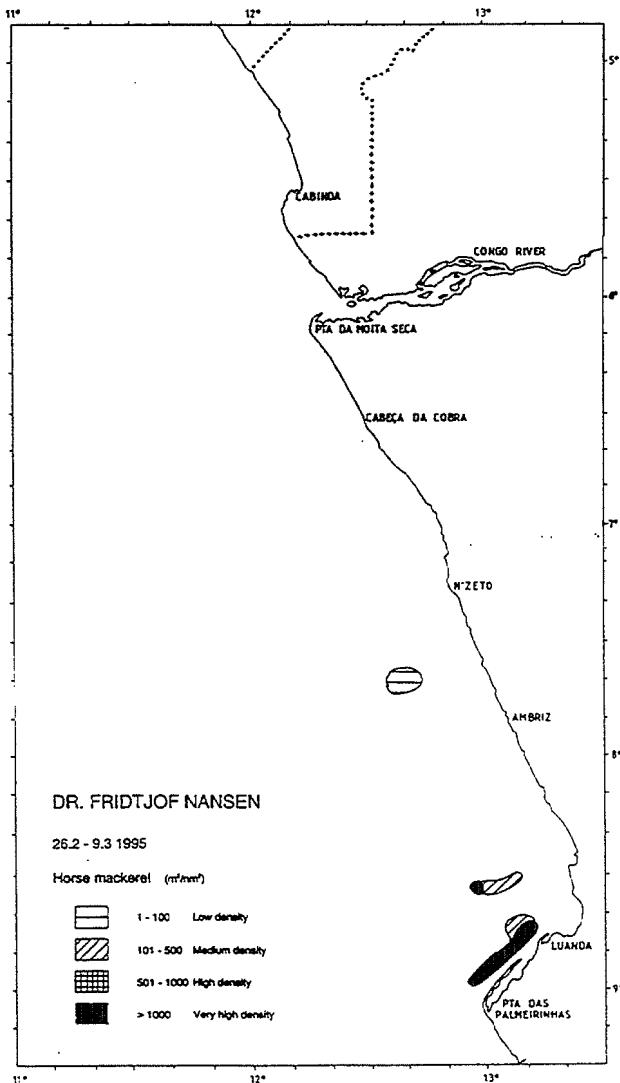

Figure 10 Distribution of horse mackerel (*Trachurus trecae*). Cabinda-Luanda.

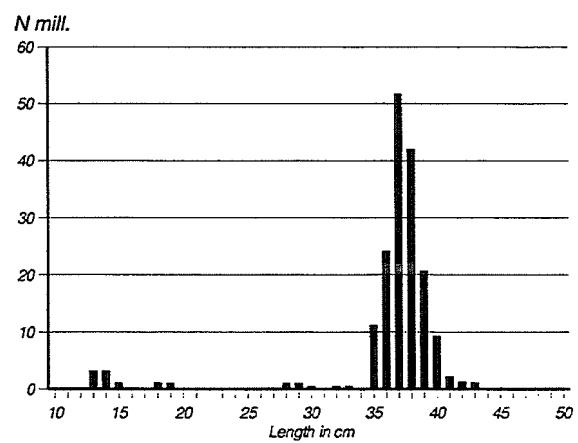

Figure 11 Total length distribution of Cunene horse mackerel (*Trachurus trecae*). Cabinda-Luanda.

#### 4.1.3 Other pelagic species

Figure 12 shows the distribution of pelagic fish type 2 for the region Cabinda-Luanda. This category includes various pelagic groups: carangids (other than horse mackerel), barracudas, scombrids and hairtails. Highest concentrations were detected in the region between Ambriz and Luanda. The biomass estimate was obtained by using an overall average length (about 31 cm) for this area and resulted in a value of about 70 000 tonnes. The composition in the catches shows a dominance of the Atlantic bumper *Chloroscombrus chrysurus* (82 %), followed by the lookdown *Selene dorsalis* (10%). The above estimate and relative abundance of the various groups are obviously very rough but still useful to give an idea of the order of magnitude of the resources and to indicate whether important changes have occurred. As compared with earlier surveys with the RV 'Dr. Fridtjof Nansen', the value obtained for this area is consistent with the average values obtained in 1985-86 (65 000 tonnes).

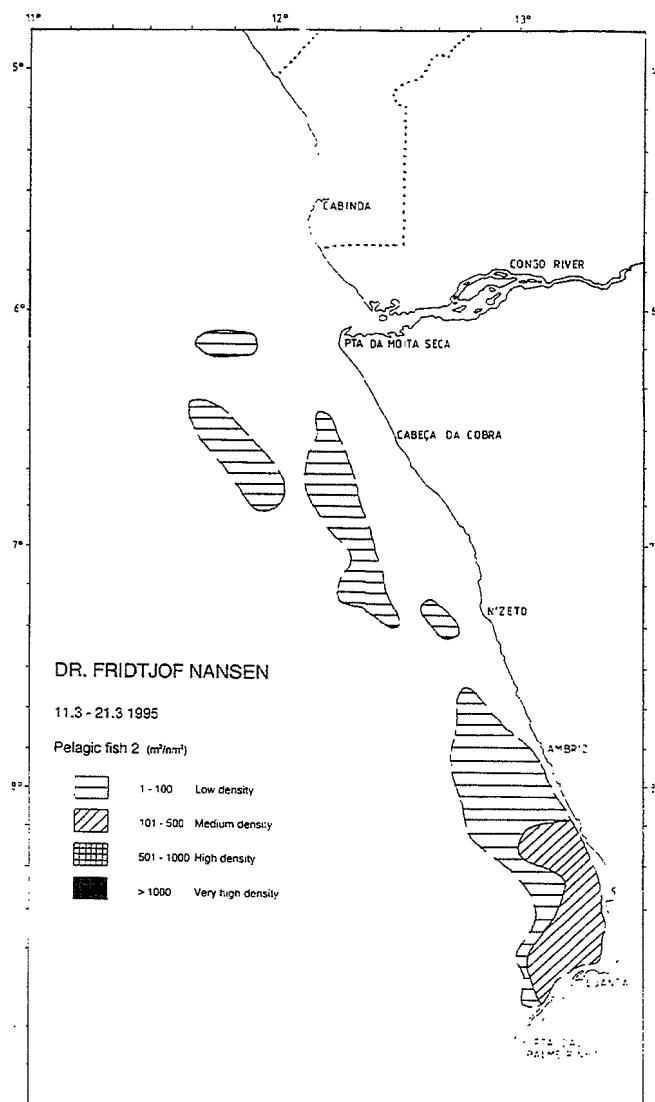

Figure 12 Distribution of pelagic fish type 2. Cabinda-Luanda.

## 4.2 Luanda-Benguela

### 4.2.1 Sardinella

Two coverages are available for this region: a first one from Luanda to Benguela which consisted of a purely acoustic survey and a second one, combined with the bottom-trawl survey. The former is characterized by a more intensive sampling on the shelf and biological sampling with the pelagic trawl, while the second followed the pattern of the bottom trawl survey, i.e. parallel tracks extending from shallow coastal waters to 800 m depth.

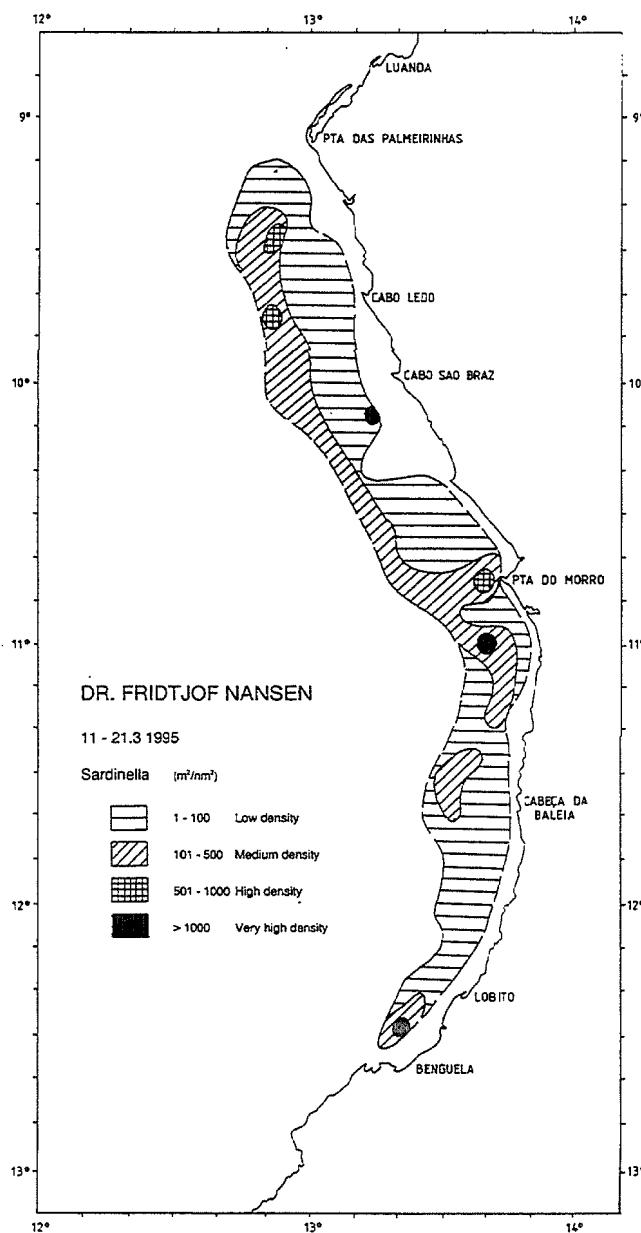

Figure 13 Distribution of *Sardinella* spp.  
Luanda-Benguela.

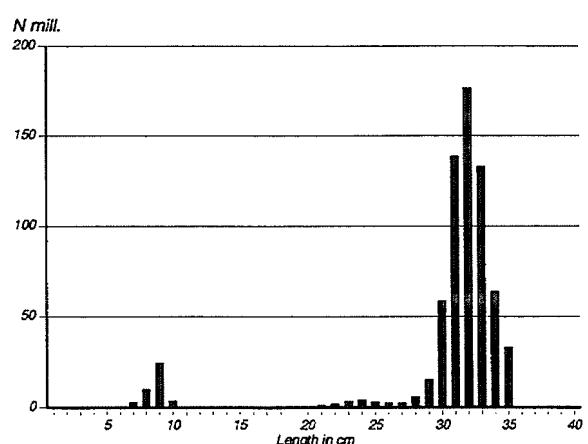

Figure 14

Total length distribution of flat sardinella (*S. maderensis*). Luanda-Benguela.

This latter coverage allowed the detection of sardinella well beyond the continental shelf edge. During nighttime it could hardly be detected from the echotraces, where it appeared dispersed in the upper thick layer of plankton. Pelagic trawling at the surface usually yielded sardinella together with hairtails and small tunas or carangids (i.e. *Trachinotus*). During daytime , it would form loose concentrations but this pattern was not regular .

Also on the shelf (Fig. 13) sardinella did not show a typical schooling behaviour. Dense schools were found only in small areas just south of Cabo Sao Braz, Punta do Morro and between Lobito and Benguela. Most of the samples included large sardinella (modal length 32 cm, Fig. 14). Juveniles (modal length 9 cm) were found in the area between Pta. do Morro and Cabeça da Baleia as well as between Lobito and Benguela, together with juveniles of other species. These seem to be important nursery areas along the Angolan coast. The biomass on the shelf was estimated to about 150 000 tonnes. This figure does not however include the 'offshore sardinella' found on the second coverage.

#### 4.2.2 Cunene horse mackerel

Apart from the very large concentration found off Punta das Palmeirinhias (already reported in section 4.1.1), horse mackerel was almost absent pelagically. It was caught, usually in small quantities, in the bottom trawl during the second coverage of this area. An acoustic estimate was not attempted because of the extremely scarce occurrence.

#### 4.2.3 Other pelagic species

Figure 15 shows that pelagic species type 2 were widely distributed in this region from shallow coastal waters, with a predominance of lookdown and Atlantic bumper, to beyond the edge of the continental shelf where scombrids and hairtails were most common. Areas of largest concentrations correspond to some of the main capes: south of Ponta das Palmeirinhias, off Punta do Morro and Cabeça da Baleia. The average length, including all the families classified in this group, was about 35 cm. The resulting biomass totalled about 100 000 tonnes. The relative abundance of the various groups in the pelagic trawl catches showed the dominance of scombrids (55 %) followed by the lookdown (22 %). However, the high abundance of scombrids is based on a single very large catch. If this is discarded, then the lookdown becomes the most important species of the group.

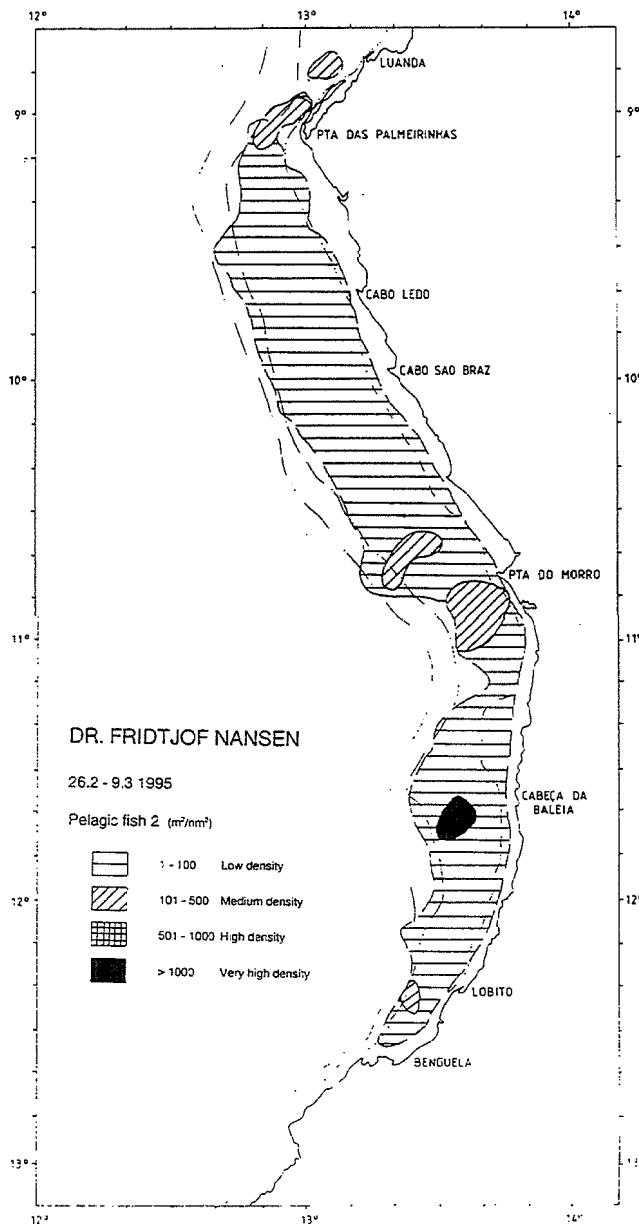

Figure 15 Distribution of pelagic fish type 2. Luanda-Benguela.

#### 4.3 Review of survey results

The present survey has resulted in unexpectedly low estimates of both sardinella and horse mackerel (Tables 3 and 4). While low biomass estimates are typical of this season in the northern region (see August 1994 survey report), the low values obtained in the central region are well below the average for the season and the lowest ever recorded by the 'RV Dr. Fridtjof Nansen'

in this region. This result is surprising considering the consistent increase in the biomass of both species observed since 1989 and reaching a total of more than 500 000 and 250 000 tonnes for sardinella and horse mackerel respectively.

\* not surveyed

This result may be put in relation with the abnormal climatic conditions found at the time of the survey discussed under Chapter 3, and in particular the thick layer of low salinity and warm

(around 29 °C) surface waters found throughout the survey area. Two main aspects can explain the low biomass estimates obtained: a possible southward migration beyond the area covered by the survey (i.e. south of Benguela) or/and a difference in schooling behaviour such as sardinella was less available to the acoustic integration system. These two aspects will be further discussed below.

### *Migration*

North-South migrations along the coast of Angola are reported for both sardinella species (Ghéno and de Campos Rosado, 1972), with a southward displacement of the adults as far south as Baía dos Tigres for the round sardinella and to Lobito for the flat sardinella during the warm season. Similar migrations were observed through the surveys of the RV 'Dr. Fridtjof Nansen' that systematically yielded higher estimates in the northern region during the southern winter period and in the central region during the warm season. The observations made last year during the February and August surveys of the pelagic resources was consistent with the above pattern. It should however be emphasized that the round sardinella was present in very small quantities. The flat sardinella, described as a more coastal and sedentary species seemed to be distributed also well offshore, beyond the continental shelf edge. The very low estimate obtained during the present survey might be due to a southward movement of the flat sardinella beyond the surveyed area. This rather massive migration would represent a previously undescribed event for this species, possibly occurred this year due to the exceptional climatic conditions. As regards the Cunene horse mackerel, its movements are not described, except from the observations made by the RV 'Dr. Fridtjof Nansen' pointing at north-south migrations between northern and central Angola. This species is most abundant off southern Angola (Benguela-Cunene) where it follows the displacements of the Benguela-Angola front. It is however possible that seasonal migration takes place including movements of the size of its area of distribution.

From the above it follows that future surveys should cover the whole Angolan coast, and possibly coordinated with a coverage off northern Namibia.

### *Methodological considerations and fish behaviour*

Acoustic sampling has the advantage of covering a resource in relative short time, i.e. to give a snapshot of abundance and distribution of pelagic species. The method suffers however of a series of bias and sources of variance that are difficult to evaluate and reduce. One of the main problems is the one related to fish behaviour, as day-night variations in school densities and in vessel

avoidance. As regards sardinella, it is common knowledge (Gerlotto, 1989) that its schooling behaviour presents important circadian differences: dense schools are typical of daytime while the opposite is true during nighttime, when schools dissolve and sardinella disperse in the upper water layers. Daytime estimates for this species are usually lower than during nighttime (Gerlotto, 1989), mainly because of vessel avoidance. For this reason, two coverages of areas with dense concentrations are advisable and this strategy was to be applied during this survey as well. During the present survey the behaviour of sardinella seemed to depart from the known pattern, with loose concentrations almost throughout the area both during day- and nighttime. We have no ground to really explain this difference, except may be for the abnormal environmental conditions encountered in the area in the course of the survey, i.e. an upper water layer about 30 m thick, with very low salinity and high temperatures. Sardinella was spread well beyond the edge of the continental shelf, over depths of more than 700 metres, usually loosely mixed with other pelagic species and within a thick layer of plankton. Under these conditions, it was very difficult to separate sardinella echos from those coming from the above layer during the scrutinizing process, possibly leading to underestimation of the biomass.

## CHAPTER 5 CATCH RATES, DISTRIBUTION, COMPOSITION AND BIOMASS ESTIMATES OF DEMERSAL FISH (SHELF)

---

The composition of the fish fauna in the catches was studied by dividing the shelf into two parts: an inner shelf, down to 70 m depth and an outer shelf, from 70 to 200 m. The positions of the trawl stations are shown in Fig. 1a-c. Records of fishing stations and catches are presented in Annex I, while pooled length distributions (weighted by the catch) of main species are shown in Annex II.

In the swept-area biomass estimates for the shelf down to 200 m, the depth strata 0-50 m, 50-100 m and 100-200 m have been applied. Mean densities by depth strata of main species, incidence and the catch distributions are shown in Annex III.

### 5.1 Cabinda-Luanda

In this region, 37 swept-area trawl stations were successfully performed on the shelf. As in the 1994 September survey, an area of about 10 nm width north of N'Zeto was not covered because of security reasons. This area includes depths to about 20 m, where demersal important groups as the croakers and grunts are usually found. These groups might therefore be under represented as compared with the results obtained in surveys carried out in the periods 1985-86, 1989, 1991 and 1992. Furthermore, the reader is reminded to consider the effect of the utilization of tickler chain on the footrope of the trawl net, already discussed in section 2.2.2.

Table 5 shows the catch rates by main species groups for the inner shelf (20 to 70 m) and outer shelf (71 to 200 m). "Demersal" comprises the commercially important families Sciaenidae, Haemulidae (=Pomadasytidae), Serranidae, Sparidae and Lutjanidae, while "Pelagic" includes, Clupeidae, Carangidae, Scombridae, Sphyraenidae and Trichiuridae (the latter family is actually mainly benthopelagic). The catch rates of both these groups were highest on the inner shelf. Here the proportion of the valuable demersal families was about 50 % of the total catch, while this proportion was about 34 % on the outer shelf. Of the remaining groups, shrimps (mainly *Penaeus notialis*) were only about 1.5 % of the catches on the inner shelf. This species was caught in the area between Luanda and Ambriz, between 20 and 30 m depth.

Table 5 Catch rates by main groups in swept area bottom trawl hauls on the shelf (kg/hour). CABINDA-LUANDA.

Comparison with the last bottom trawl survey carried out by the RV 'Dr. Fridtjof Nansen' in this area and at the same season, i.e. survey I/1989, shows that the catch rates obtained during the present survey are higher (about 80%) for both the pelagic and the demersal groups on the inner shelf. The comparison does not however take into account changes in the bottom trawl such as the use of larger doors and longer sweeps and the use of tickler chains, whose effects have not been evaluated yet. Experiments made at higher latitudes show for example that with the use of longer sweeps and larger doors the herding effect is enhanced so that the catchability coefficient increases. The higher catch rates might in fact be the result of this effect. In the deeper part of the

shelf (70 to 200 m) the catch rates were only 20% higher, while for the pelagic species this value was 50% lower.

Catch rates of pelagic groups broken down to families (Table 6) are presented just to give some indication of the forms present. On the inner shelf Carangids, specially *Chloroscombrus chrysurus* dominated while on the outer shelf hairtails (*Trichiurus lepturus*) showed the highest catch rates.

Table 6 Catch rates of main pelagic families in swept area bottom trawl hauls for the shelf(kg/hour. CABINDA-LUANDA.

Table 7 shows the catch rates of the most important demersal species grouped into families. On the inner shelf grunts and seabreams were the most abundant valuable groups while on the outer

shelf, the seabreams, and particularly *D. angolensis* were the most common. The mean catch rate of sparids was lower both in the inner and the outer shelves as compared with survey I/1989. This might in fact mean a general decrease taking into account the possible higher herding effect of the new doors.

Figure 16 shows the distribution of seabreams in the region Cabinda-Luanda. This coincides with the intermediate and deeper shelf sparid-community that largely occupies this region. *Pagellus* is also an important component of this community. Combined catch rates of the valuable sparid species (including the genera *Dentex*, *Sparus* and *Pagellus*) reached above 100 kg/hour in some areas between N'Zeto and Cabeça da Cobra and above 200 kg/hour trawling off Ambriz.

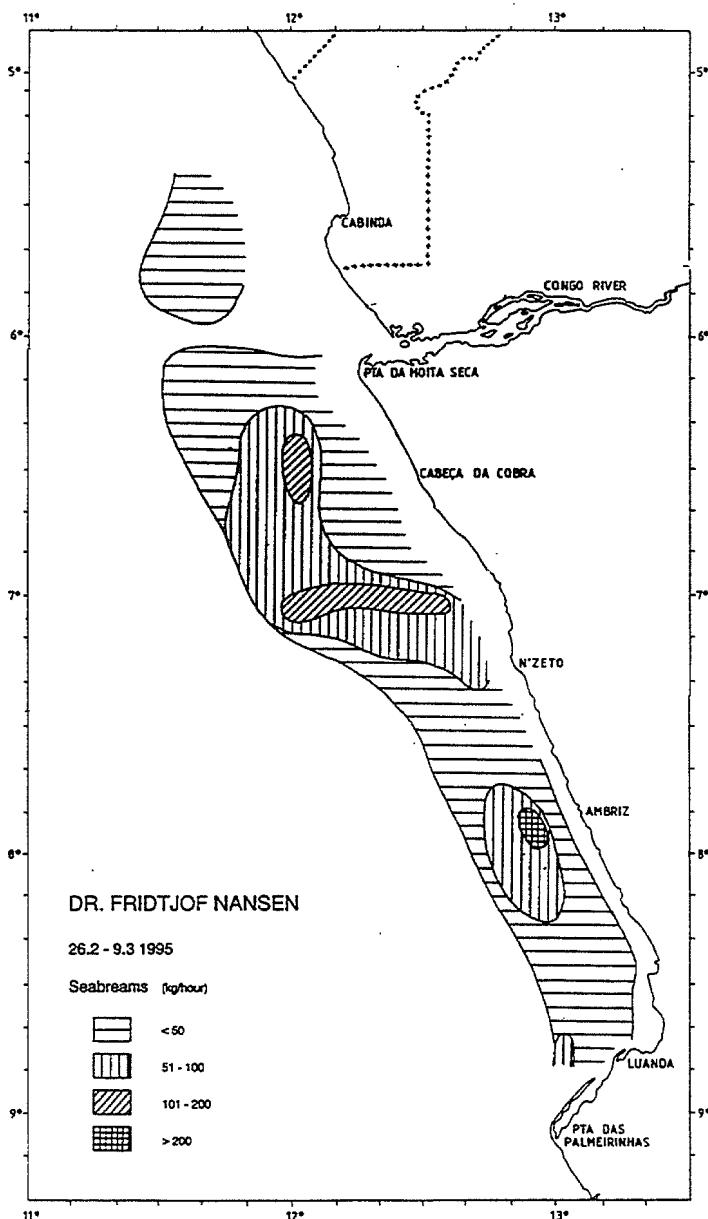

Figure 16 Distribution of seabreams (family Sparidae). Cabinda-Luanda.

Table 8 shows the biomass estimates for the main commercial groups and for other groups that occur in sizeable quantities.

\* excluding big-eye grunt

♀ summer season (February-March)

♦ winter season (July-September)

The present biomass estimate for the seabreams is consistent with the results obtained in the same period in previous years. Wintertime estimates are the highest and the last year estimate is particularly high. This estimate has been affected by the occurrence of a few very high catches of *Dentex barnardi*. One of the reasons of the differences between summer and winter periods is probably due to the higher catchability of these species during spawning that takes place in wintertime. This pattern is consistent for the sum of the important demersal families, where higher estimates were obtained in the winter surveys.

The second group, including mostly pelagic or semipelagic species that usually form an important part of the catches show large year to year variations as it might be expected considering their behaviour and the inappropriateness of bottom trawl to measure their abundance. Noteworthy is however the very low value of horse mackerel in the present survey that confirms the results obtained from the acoustic system.

## 5.2 Luanda-Benguela

The shelf area, from 20 to 200 m depth, was covered with 44 bottom trawl stations. Catch rates by station for the main groups are presented in Table 9. In tables 10 and 11, the pelagic and demersal groups respectively are further separated into the main taxa.

The families and species included under each group are as specified under section 5.1. The relative abundance of the main resources groups is very similar to what found in the northern region: on the inner shelf, about 50% of the catch rates consisted of demersal fish and 27% of pelagic species. The other groups (sharks, shrimps, and cephalopods) only represent a minor component of the catches. *Penaeus notialis* was less common than in the northern region while cephalopods, particular *Sepia officinalis* were more abundant. On the outer shelf (70-200 m) about 60% of the catch consisted of valuable demersal species, almost double as much as in the north.

Table 9 Catch rates by main groups in swept area bottom trawl hauls on the shelf (kg/hour). LUANDA-BENGUELA

Comparison with Survey I/1989 shows that caches of valuable demersal species are at similar levels (although differences in the gear used should be considered). The pelagic groups is however much reduced on the inner shelf, mainly due to a decrease in catches of the hairtails (Table 10).

As regards composition of important demersal families (Table 11), most remarkable is the decrease in the catch rate of grunts on the inner shelf and the substantial increase of rates of

croakers (mainly *Umbrina canariensis*) on the outer shelf. The seabreams show a slight increasing trend.

Figure 17 shows the distribution of the catch rates of seabreams on the shelf and upper slope areas. The highest abundance was found in the area Cabeça da Baleia-Benguela, on the deeper shelf and upper slope areas, consisting mainly of *Dentex macrophthalmus*. This species is distributed and most abundant further south and a full coverage of the stock, possibly including

northern Namibia, is recommended. Areas of higher catch rates were also found off Pta. do Morro and Cabo Ledo to Cabo Sao Braz.

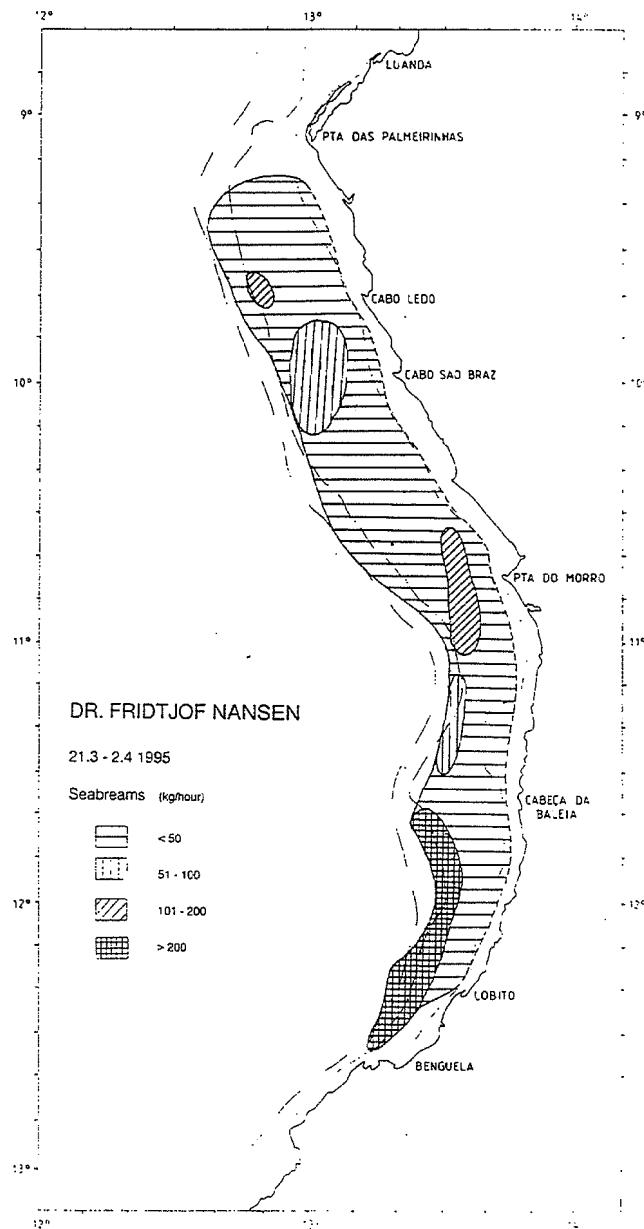

Figure 17 Distribution of seabreams (family Sparidae). Luanda-Benguela.

Table 12 shows the results from the swept-area analysis from the present and previous surveys. The total biomass of valuable demersal groups is at the same level as evaluated last year. However, comparison with the results obtained in surveys carried out in the same season shows a higher value. Again these results should be considered with care, until experiments are

performed to evaluate the differences in catchability with the new doors and the use of tickler chains.

\* no swept area hauls available

\*\* excluding big-eye grunt

⊗ summer season (February-March)

♦ winter season (July-September)

Of non-demersal groups, but usually abundant and well represented in the bottom trawl catches, the horse mackerel and the hairtails show both an important decrease. This however, at least for the horse mackerel, might be due to a southward migration caused by the 'particularly warm' environmental conditions.

## CHAPTER 6 CATCH RATES, DISTRIBUTION, COMPOSITION AND BIOMASS ESTIMATES OF DEEP-WATER SHRIMP AND HAKE

---

The slope off Cabinda-Luanda was covered with 38 hauls distributed as follows: 19 in the depth range 200-400 m and 19 in the range 400-800 m. The slope from Luanda to Benguela was covered with 43 hauls, with 20 in the range 200-400 m and 23 in 400-800 m. The results from the swept area analysis by depth intervals are presented in Annex III, C and D. Tables 13 and 14 show the composition of the catches by major groups. These tables provide information on bycatch composition in the commercial shrimp fisheries. The groups included under 'Demersal' are families of commercial interest (including the hake). The category 'Shrimps' includes all species caught.

Table 13 Catch rates (kg/hour) by main groups in swept area bottom trawl hauls on the slope. CABINDA-LUANDA.

Shrimps (including the non-commercial families) make up about 25 % of the total catches on the slope in the area Luanda-Cabinda, but only about 10% in the Luanda-Benguela region. The 'Pelagic category' consists mainly of hairtails. The substantial 'Others' group includes a wide variety of slope species of no commercial value. A comparison with the results from last year survey shows an increase in the catch rates of shrimp in the northern region, while the value for the Luanda-Benguela region is about the same.

Table 14 Catch rates (kg/hour) by main groups in swept-area trawl hauls on the slope.

## 6.1 Deep-water shrimp

The slope off Cabinda was covered with 24 stations where deep-water shrimps were caught in 22 stations (Table 13). Table 15 shows the catch rates of the rose shrimp (*P. longirostris*) and the striped red shrimp (*A. varidens*) by depths. The mean catch of *P. longirostris* was 12.1 kg/h and for *A. varidens* 3.8 kg/h.

Table 15 Catch rates of main shrimp and bycatch species in swept area bottom trawl hauls on the slope (kg/hour). CABINDA-LUANDA

As in the previous surveys the maximum catch rate for *P. longirostris* was observed in the 200-300 m depth stratum. Fig 18 shows the distribution of *P. longirostris*. It was found throughout the survey area, with highest concentration between Ambriz and N'zeto and north of Cabinda.

The highest concentration of *A. varidens* was recorded in the 400-500 m depth stratum. Fig. 19 shows the distribution area of *A. varidens*. The concentration throughout the area was constant (< 20 kg/h).

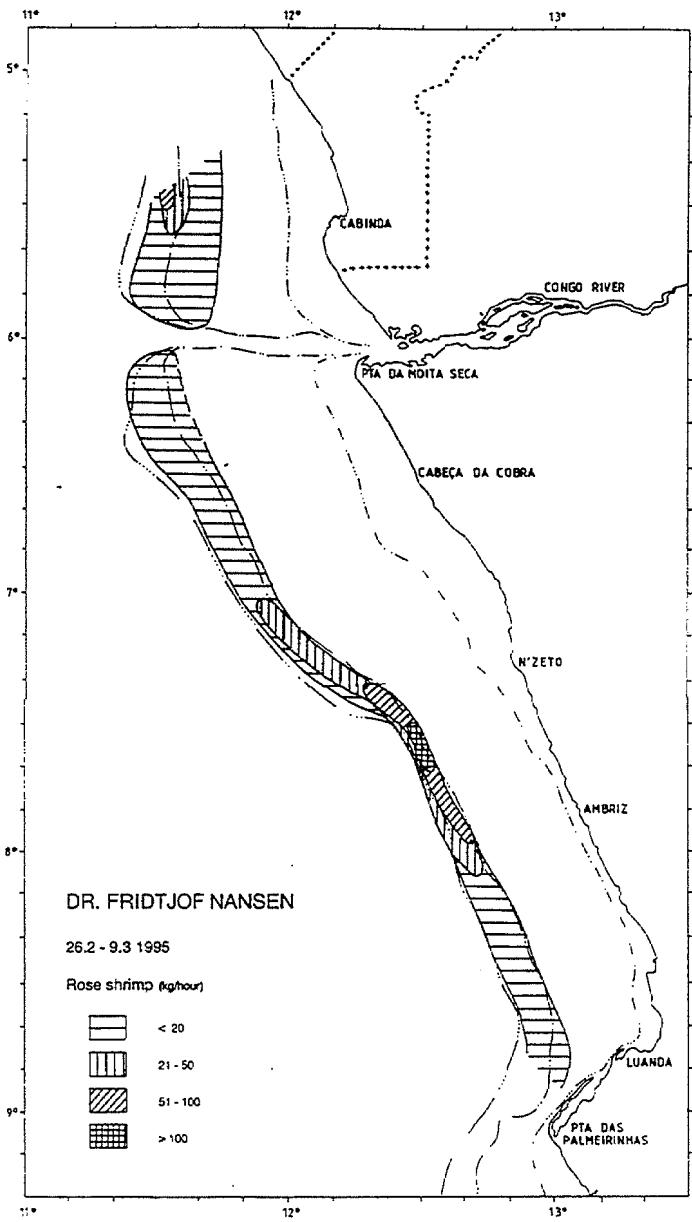

Figure 18 Distribution of rose shrimp (*Parapenaeus longirostris*). Cabinda-Luanda.

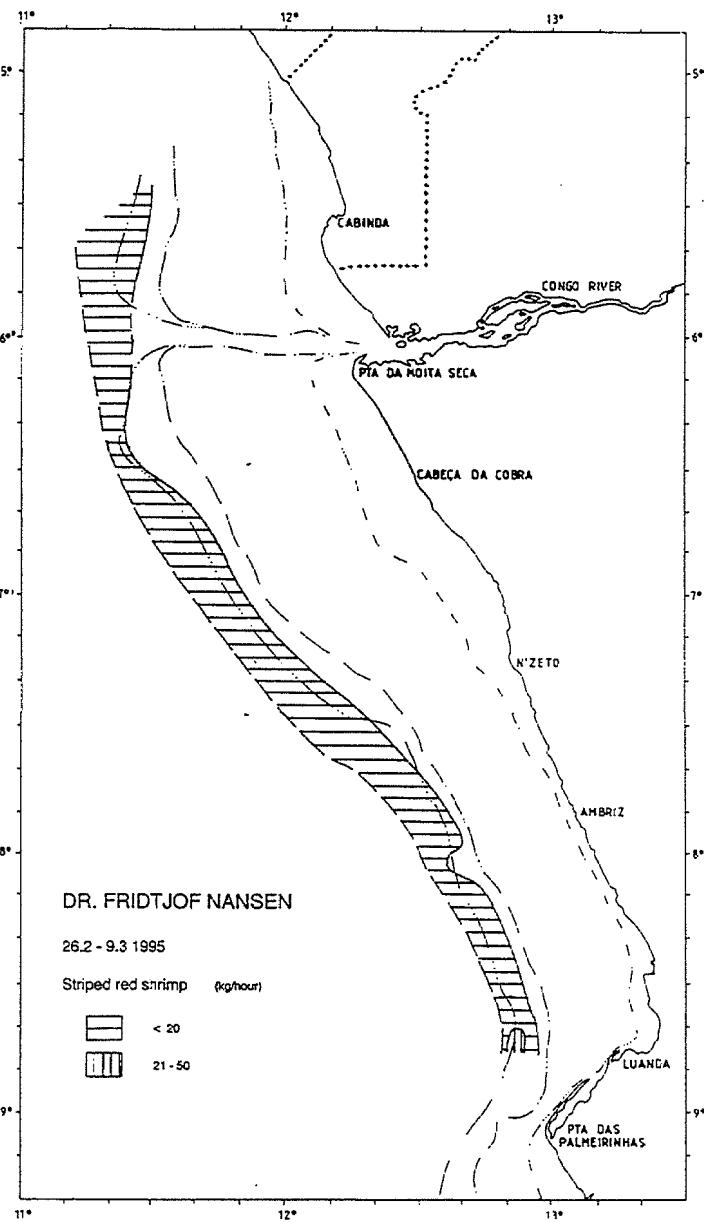

Figure 19 Distribution of striped red shrimp (*Aristeus varidens*). Cabinda-Luanda.

In the Luanda-Benguela region (Table 16) 43 stations were performed and shrimp was caught at 42 stations. Mean catches of rose shrimp were lower than in the northern region (7.9 kg/h) while the catches of striped red shrimp were higher (12 kg/h). These results are comparable with those obtained last year. This is however surprising considering the expected higher catches as a

consequence of the introduction of tickler chain on the bottom trawl. This might point to an actual decrease in the abundance of the above species. Figures 19 and 20 show the distribution of rose shrimp and striped shrimp respectively, in the Luanda-Benguela region. Catches were below 20 kg/h in most the distribution are of both species. The best fishing area for both species resulted the slope between Cabeça da Baleia and Benguela.

Table 16 Catch rates of main demersal families/species in swept area bottom trawl hauls for the slope (kg/hour). LUANDA-BENGUELA.

The mean catch rate of the rose shrimp was highest between 200 and 400 m (about 16 kg/h) while highest rates for striped red shrimp were obtained between 300 and 400 m (17 kg/h). The latter species had highest frequency of occurrence in the depths greater than 500 m, with catch rates of about 12 kg/h.

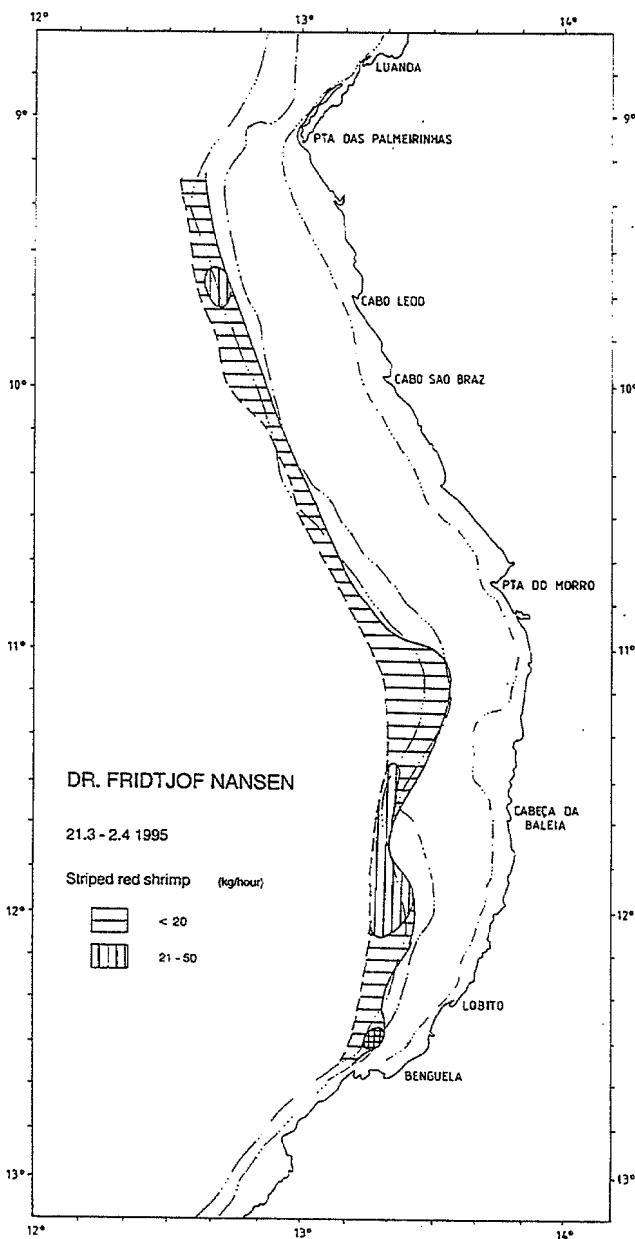

Figure 20 Distribution of rose shrimp (*Parapenaeus longirostris*). Luanda-Benguela.

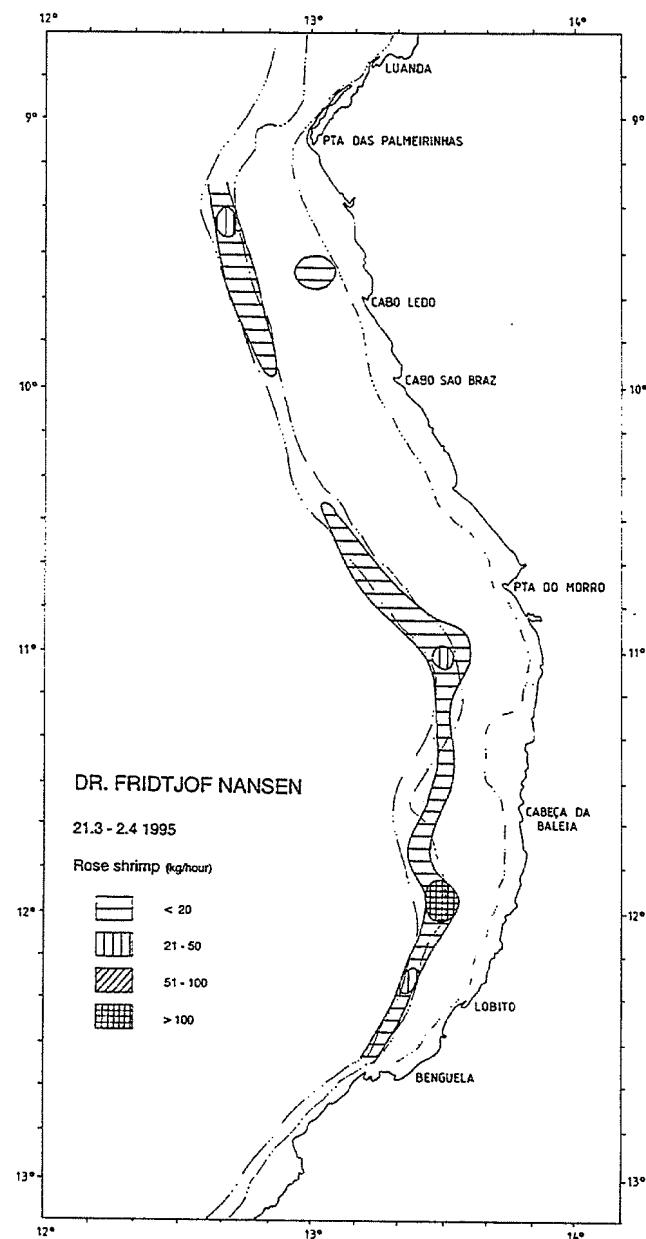

Figure 21 Distribution of striped red shrimp (*Aristeus varidens*). Luanda-Benguela

The biomass estimates for two species by area are given in table 17. Confidence intervals were calculated for the 1995 survey only and were about  $\pm 10\%$  for *P. longirostris* and  $\pm 7\%$  for *A. varidens*. In the northern region the biomass of *P. longirostris* has increased by 41% from the last year. This increase could be related to better gear performance. However, for *A. varidens* a decline of the biomass by 18% was observed. In the region Luanda-Benguela the trend appears to be opposite, with rose shrimp showing a decline of about 35 % and the striped red shrimp a slight increase. The total biomass of valuable shrimps is lower as compared to the results obtained in 1986, but appears to have maintained stable levels in later years. This apparent stability probably mask a real decline in the biomass because of the more efficient gear used in this year

survey. A more realistic evaluation of biomass trends will be possible after comparison in the change of efficiency with the introduction of tickler chains.

## 6.2 Benguela hake

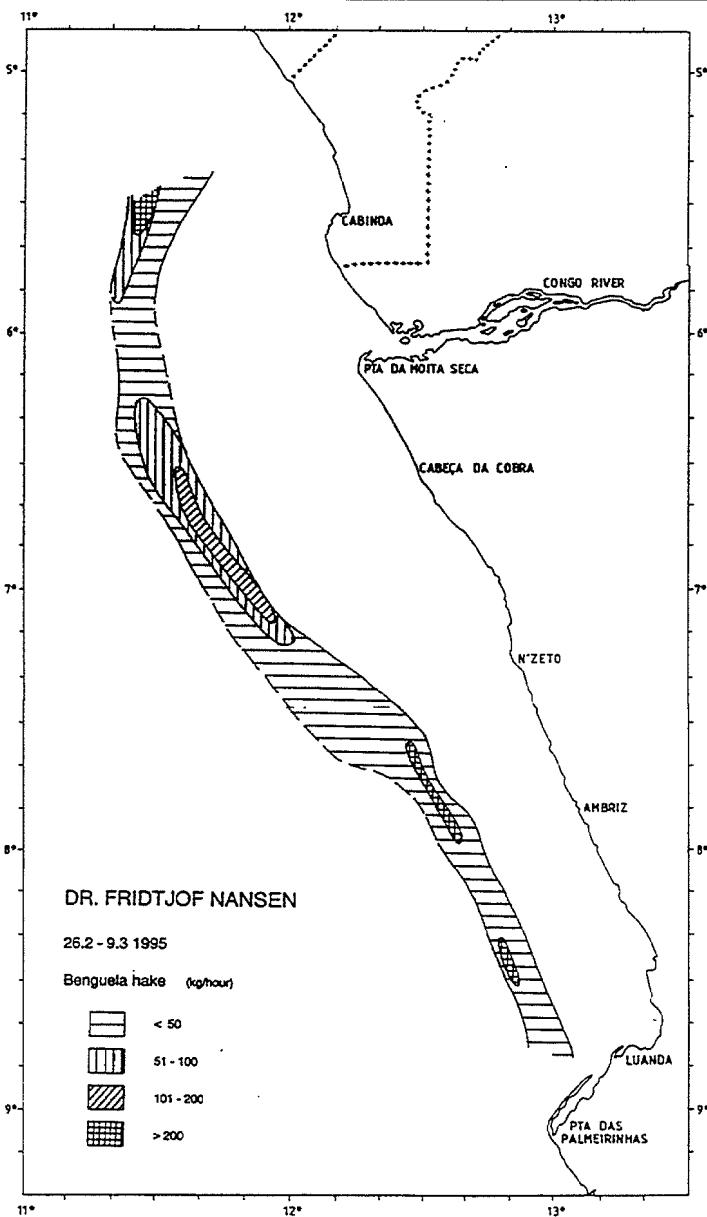

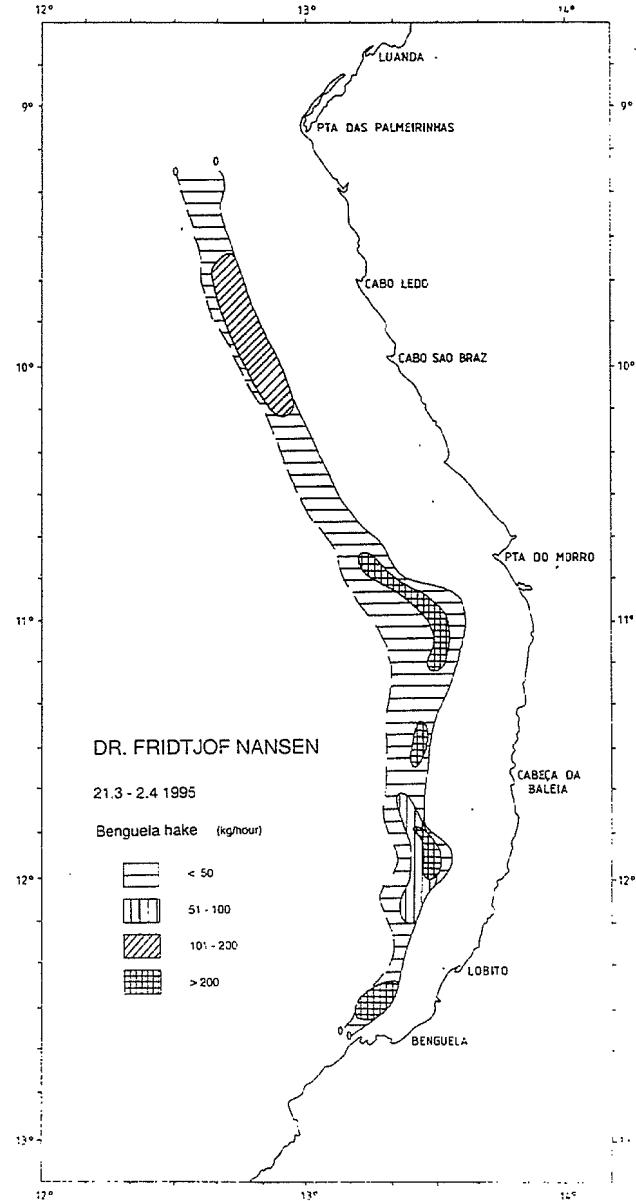

The catch rates of Benguela hake (*Merluccius polli*) are shown in tables 15 and 16 for Luanda-Cabinda and Luanda-Benguela respectively. Figures 22 and 23 show the distribution of catch rates in these two regions. Benguela hake showed a continuous distribution on the slope both in the northern and central regions. It was mainly found on the slope from about 300 to 600 m depth, with highest concentration (> 200 kg/h) observed in three areas; off Cabinda, between N'Zeto-Ambriz and off Ambriz -Luanda.

In the Luanda-Beguela region the highest catch rates (about 200 kg/h) were obtained in the depth range 300 to 400 m. Areas of high concentrations were encountered off Cabo-Ledo to Cabo Sao Braz, off Ponta do Morro and between Cabeça da Baleia and Benguela.

Biomass estimates of hake are presented in table 16. In the Luanda-Cabinda region there is an increase of about 30 % in the biomass estimate although this value still continue the low level trend noticed since 1986. In the Luanda-Benguela region there is a decline of about 25 %, consistent with the declining trend of previous years.

Table 18 Biomass estimates of hake by area and year/period of investigation (tonnes).

## **Annex IV Instruments and fishing gear used**

The Simrad EK-500/38kHz scientific sounder was used during the survey for fish abundance estimation. The Bergen Echo Integrator system (BEI) was used to scrutinize the acoustic records from the 38kHz echo sounder, and to allocate integrator values to fish species.

The details of the settings of the 38kHz echo sounder where as follows:

### **Tranceiver-1 menu (38 kHz lowering keel)**

Transducer depth	0.00 m
Absorbtion coeff.	10 dB/km
Pulse length	medium (1ms)
Bandwidth	wide
Max power	2000 Watt
2-way beam angle	-21.0 dB
SV transducer gain	28.0 dB
TS transducer gain	27.9 dB
Angle sensitivity	21.9
3 dB beamwidth	6.8 dg
Alongship offset	0.00 "
Athwardship offset	0.04 "

### **Display menu**

Echogram	1 (38 kHz)
Bottom range	15 m
Bottom range start	10 m
Sv colour min	-72 dB

### **Printer- menu**

Echogram	1 (38 kHz)
Range	100, 250 and 500 m
Range start	0
Bottom range	12 m
Bottom range start	10 m
Sv colour min	-72 dB
TVG	20 log R

**Bottom detection menu**      Minimum level -50 dB

## Fishing gear

The vessel has two different sized "Åkrahamn" pelagic trawls and one "Gisund super bottom trawl". All three trawls were used during the survey.

The bottom trawl has a headline of 31 m, footrope 47 m and 20 mm meshsize in the codend with an innernett of 10 mm meshsize. The estimated opening is 6 m (observed 5.7) and distance between wings during towing about 18 m. The sweeps are 40 m long. The trawl is equipped with a 12" rubber bobbins gear. The doors are of 'Thyborøn' combi type, 7.81 m<sup>2</sup>, 1670 kg, their distance while trawling about 46 m in average. This distance is kept constant at all depths by the use of a 9.5 m strap between the wires at 130 m distance from the doors (applied at depths greater than 60 m). A tickler chain (44 m in total) was attached at the footrope.

The SCANMAR system was used both on pelagic and bottom trawls. This equipment consists of sensors, a hydrophone, a receiver, a display unit and a battery charger. Communication between sensors and ship is based on acoustic transmission.

The doors are fitted with sensors to provide information on their distance.

A height sensor is fitted to the bottom trawl to measure the trawl opening and provide information on clearance.

The pelagic trawl is equipped with a trawleye that provides information on the trawl opening and the distance of the footrope to the bottom.
