CRUISE REPORTS "DR. FRIDTJOF NANSEN"

SURVEYS OF THE FISH RESOURCES OF NAMIBIA

Cruise Report No 1/96

Surveys of the hake stocks
12 Jan. - 19 Feb. 1996

Ministry of Fisheries & Marine Resources
Swakopmund
Republic of Namibia

Institute of Marine Research
Bergen
Norway

The DR FRIDTJOF NANSEN RESEARCH PROGRAMME is sponsored by the Norwegian Agency for Development Cooperation (NORAD), the Food and Agriculture Organization of the United Nations (FAO), and the United Nations Development Programme (UNDP). The programme in Namibia is organized and planned under agreements between NORAD, Namibian authorities and the Institute of Marine Research, Norway. Its execution is the responsibility of the Institute of Marine Research, Bergen in cooperation with the Ministry of Fisheries & Marine Resources of Namibia. The programme has comprised the following surveys:

Survey	1/90	25 January to 19 March 1990
"	2/90	27 May to 20 June 1990
"	3/90	11 September to 6 October 1990
"	1/91	25 January to 23 March 1991
"	2/91	23 October to 16 December 1991
"	1/92	23 April to 21 June 1992
"	2/92	20 October to 16 December 1992
"	1/93	20 January to 19 March 1993
"	2/93	21 April to 25 May 1993
"	1/94	19 January to 21 February 1994*
"	2/94	26 April to 24 June 1994
"	3/94	19 October to 24 November 1994
"	1/95	16 January to 19 February 1995
"	2/95	22 April to 21 June 1995
"	3/95	27 September to 7 October 1995

* First survey with the new R/V 'Dr. Fridtjof Nansen'.

CHAPTER 1 INTRODUCTION

1.1 GENERAL OBJECTIVES

Following an offer from NORAD extended through FAO and UNDP, an agreement was reached in Windhoek in January 1990 between the UNDP Resident Representative and Namibian authorities for the execution of a programme of surveys of the fish resources of the Namibian shelf with the RV 'Dr. Fridtjof Nansen'.

The main objectives were agreed as follows:

To describe the distribution, composition and abundance of the most important fish resources. Small pelagic fish, including horse mackerel, pilchard and anchovy would be investigated by the acoustic integration method combined with sampling with mid-water and bottom trawls. A swept area trawl survey programme would be used for the demersal stocks. All catches would be sampled by species, weight and numbers, including biological sampling of the commercially important stocks.

To carry out environmental studies including recording of surface temperature on a continuous basis and hydrographic sampling on a series of fixed profiles.

1.2 OBJECTIVES OF SURVEY 1/1996

The main objectives were to continue to monitor the abundance, geographic distribution and size composition of the hake stocks within the Namibian EEZ and to describe the trends in development of the hake stocks within the programme perspective of support to rebuilding of the hake stocks since independence. These objectives are in line with the national priorities set in the Government White paper of 1990. As secondary objectives, the lesser abundant, but commercial important species as monk, sole and kingklip would be studied in detail as these species form a natural bycatch of a hake survey in Namibia. As part of the hake research, environment parameters were continuously recorded in order to improve knowledge on the influence of the environment on the distribution and natural mortality of the hake stocks.

The acoustic system was used to observe possible mid-water occurrences of the hakes. The survey design for the swept-area trawl programme was based on a semi-random distribution of hauls along regular transects perpendicular to the coast. The transect distance was normally between 20 and 30 nm. On the slope the stations were laid out to cover the depth ranges of the two hake species. The on-shelf stations were laid out 10 to 15 nm apart until the zero line of hake distribution was found. Information from the acoustic system was also used in this process. Biomass estimates of hake were based on post stratification by depth and density aggregations.

A part objective was also to carry out comparative fishing with R/V "Africana" in order to find possible correction factors to facilitate harmonization between The Republic of South Africa and Namibia on the assessment of hakes.

1.3 PARTICIPATION

The scientific staff consisted of:

From Namibia:

Filimon DAUSAB, Michael EVENSON (12-31/1), Johnny GAMATHAN, Hashali HAMUKUAYA (12-31/1), Heinrich LESCH, Lima MAARTENS (31/1-19/2), Malakia SHIMANDA, Shaun WELLS (31/1-19/2).

From IDFP, Chile:

Sergio LILLO VEGA (31/1-19/2).

From Norway:

Oddgeir ALVHEIM, Terje HAUGLAND, Ingvar HUSE (12-31/1), Jarle KRISTIANSEN, Tore STRØMME (31/1-19/2).

1.4 NARRATIVE

The course tracks with the positions of the fishing and hydrographic stations are shown in Figures 1 a-c.

The vessel left Walvis Bay on the afternoon of 12 January and steamed south to commence the work between Lüderitz and Orange River. Trawling inshore of 300 m was mainly carried out during daylight hours, but the deeper stations on the slope were sometimes carried out during dark. CTD-stations were taken on every trawl station in order to map the environment conditions in relation to fish distribution. On 15 January the vessel met with R/V "Africana" for a three day trawl intercalibration exercise. After that the ship called on Lüderitz to exchange chief engineers, whereupon the survey work was commenced again from Orange River. On 30 January the ship called at Walvis Bay for crew change, having covered the area south of Walvis Bay.

The vessel left for the last leg of the survey on 1 February, and the work continued northwards following the standard grid pattern. The northern border was reached on 15 February and on the way south extra sampling was conducted in shallow areas where high aggregations of young hake had been observed, in order to map the inner limit of these distributions more accurately. Arrival in Walvis Bay was on 18 February.

The weather conditions were in periods rough during the southern leg but it was not necessary to interrupt the work. On the northern leg the weather conditions were mostly favourable.

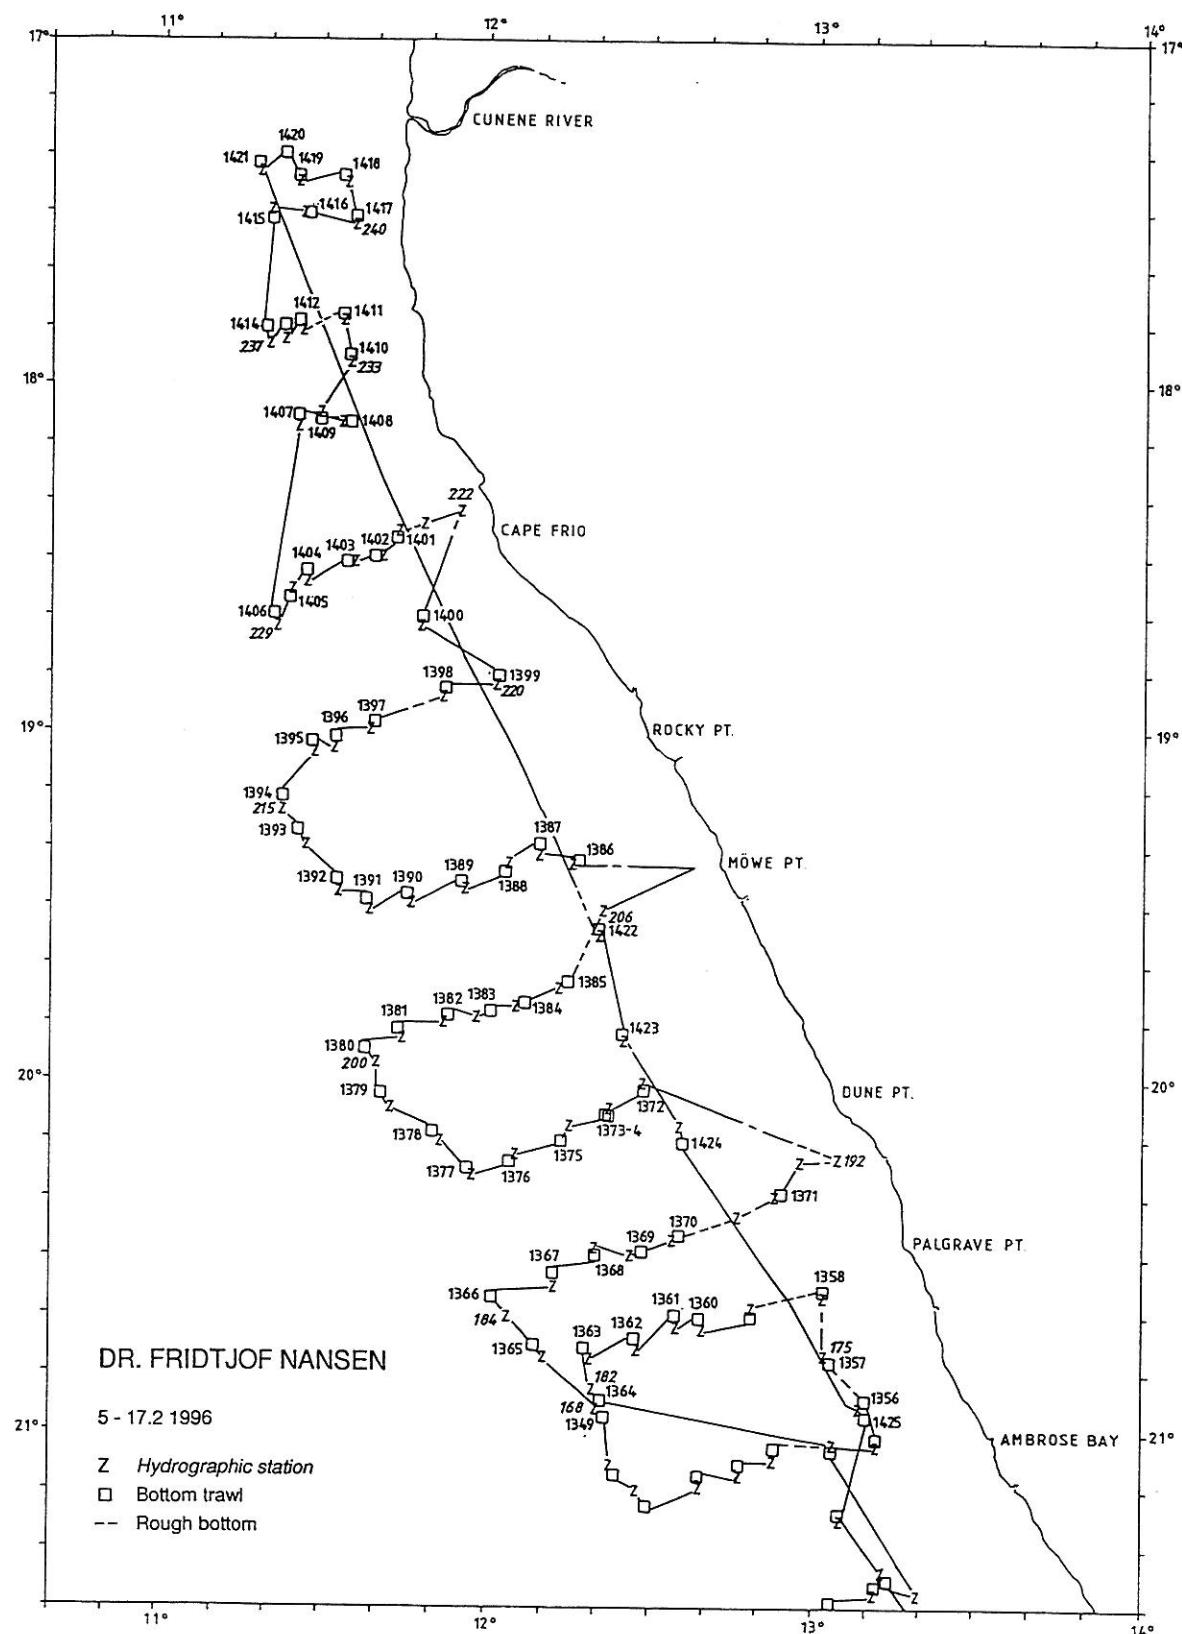

Figure 1c

Northern Region (Ambrose Bay to Cunene River). Course tracks, fishing stations and hydrographic stations.

CHAPTER 2 HYDROGRAPHY

Strong southern winds prevailed during the first part of the survey until Cape Cross, whereafter a calm period occurred. The wind conditions along the survey track are shown in Figures 2a-c

Sea temperature at 5m depth was recorded continuously along the cruise track and is shown in Figures 3a-c. Six hydrographic sections were collected at the standard locations and are shown in Figures 4a-c. The surface temperature shows two upwelling cells with centres off Lüderitz and Walvis Bay, and a smaller and perhaps weaker cell around Cape Frio.

Bottom oxygen level was recorded at all fishing stations (Figures 5a-c), to monitor its effect on the hake distribution. Low oxygen conditions defined as $O_2 < 0.5\text{ ml}$ characterize the shelf environment beyond 200 m bottom depth between Lüderitz and Cape Frio, extending down to 500m off Easter Point, Dune Point and Rocky Point. During the preceding 13 surveys a seasonal pattern has been observed in the build up and flush out of oxygen deficient waters on the Namibian shelf with maximum buildup after the summer growth season and usually flush out during April-May. In the May 1994 survey there was not a normal flush out due to unfavourable oceanographic conditions and the oxygen depleted waters could accumulate over two years. In May 1995 that the 0.5 oxycline again had moved shorewards indicating a previous flush out. During the recent survey that the oxygen deficient waters had build up to the level of January 1995 and perhaps even more.

As during previous surveys, the oxygen maps are overlaid with the distribution maps of the Cape hake, Figures 6a-c. They show that only minor fractions of the hake distributions are found in waters of less than 0.25 ml O_2/l , while the fish seems to sustain levels just beyond that limit.

CHAPTER 3 RESULTS OF THE ACOUSTIC AND TRAWL SURVEY

3.1 DISCUSSION OF METHODS

In the trawl survey programme all catches were sampled for composition in weight and numbers by species. The bottom trawl has a headline of 31 m (float line), a footrope of 47 m, headline height of 5-6 m and a distance between the wings during towing of about 21 m. All trawl hauls were monitored by SCANMAR trawl sensors (trawl depth, headline height and distance between the doors). This technology allows to determine with improved accuracy the actual time the trawl is on the bottom. For conversion of catch rates to fish densities the area between the wings is assumed to be equal to the effective fishing area and the retention factor q is equal to 1. With the new vessel, starting from January 1994, a new trawl gear was introduced with smaller bobbins. This gear is expected to give better bottom contact and higher catch rates for bottom dwelling species like monk and sole. For the hake species the new gear is assumed to have no difference in performance. The trawl doors are Thyborøen 7.9 m², but the net, warp and wire dimensions are as with the former vessel (see Annex IV). The length of a haul over bottom, recorded as distance trawled, was measured by log pulses from the GPS, and checked against the lengths of the traces of the hauls on the GPS plotter system.

The problem of mid-water occurrence of hake and its effect on the swept area assessments has been discussed in earlier cruise reports. As in previous

Table 1 Hakes. Frequency of observations of hake in mid-water during trawling. No. of trawl stations with swept area densities and no. of stations with observations of hake above 5 m from bottom with acoustic density estimate (tonnes/nm²).

investigations off-bottom hake in mid-water constituted only a minor problem in the south and in the central area. In the north it made up an average 9% addition to the demersal biomass in the day hauls. In a more limited number of night hauls the average correction were 56, 33 and 43% (Table 1).

Fish abundance (in weight and number) by length groups or by cohorts are found by combining the total abundance obtained from catch records with the length distributions of the species. Length distributions in fish aggregations are obtained by pooling the length frequencies from trawl stations using the catch rates as weighting factor, and regional length based estimates are obtained through pooling the length frequencies from these areas with the biomass of the aggregations as weighting factor.

3.2 SOUTHERN REGION, ORANGE RIVER TO ST. FRANCIS BAY

The complete record of the fishing stations is shown in Annex III. Table 2 shows the catch rates of the main commercial species standardized to kg/hour for the shelf and the slope separately. For the hakes the mean catch rates on the shelf are about the same level as during the previous survey in May 1996, while on the slope there is an increase of almost 50% which can be explained by seasonal migration from the south. Monk and kingklip show low catchrates on the shelf (50-259m) while there is a considerable increase in the catchrates, about 300% for both species in the deeper waters. The late summer season is known to be the best for fishing monk and the increased catchrates could be associated with seasonal behaviour, making it more vulnerable to the trawl.

Table 2 Southern Region. Catch rates in kg/hour by main groups by swept area bottom trawl for the shelf and the slope.

The depth distribution of the two hake species based on the catch rates converted to densities is shown in Table 3. A comparison with the previous survey shows that the catch rates for the Cape hake has more than doubled from 540 to 1210 kg/hour in the 250-350 m depth zone, while for the deep water hake the increase has occurred in the 350-450m zone (from 580 to 960 kg/h) and in the 450-550m zone (from 360 to 610 kg/h). In the 250-350 m zone, the zone of increase for the Cape hake, the deep water hake has shown a reduction in the catch rates (from 430 to 310 kg/h).

Table 3 Southern Region. Depth distribution of the two hake species. Mean densities in tonnes/nm² and mean catch rates kg/hour.

	75-250m	250-350m	350-450m	450-550m	550-650m
Cape hake					
Density	4.7	40.3	1.1	0.04	
Catch rate	140	1210	35	1	
Deep w. hake					
Density	1.0	10.5	32.1	20.4	13.0
Catch rate	30	310	960	610	390
No. of hauls	21	16	18	11	5

The distribution of the two hake species based on plots of densities by fishing stations is shown in Figures 8 and 9. These include the acoustic estimates of fish present above the 5 m bottom channel during trawling as explained above. The main concentrations of both hakes are from Lüderitz and northwards. In addition, the deep water hake extends in a narrow band around 500m bottom depth southwards.

Biomass estimates based on a post-stratification of the densities as shown in Figures 8 and 9, give 169 000 tonnes for the Cape and 202 000 tonnes for the deep water hake (Table 4), an increase of 16% for the Cape hake and 44% for the two species combined since the previous survey. The 95% confidence limits give a range of $\pm 49\%$ on the estimate of the Cape hake and $\pm 35\%$ of the deep water hake. The wide confidence limits on the Cape hake is mainly caused by two very high catches on young hake on the shelf, and a separate analysis on the fishable part of the population would probably give more narrow ranges.

Table 4 Southern Region. Estimates of total biomass by surveys, 1 000 tonnes.

Year/Survey	Cape hake	Deep water hake
90/1	130	22
90/3	130	25
91/1	113	31
91/2	80	82
92/1	200	145
92/2	160	125
93/1	210	150
93/2	180	115
94/1	200	160

96/1	169	202

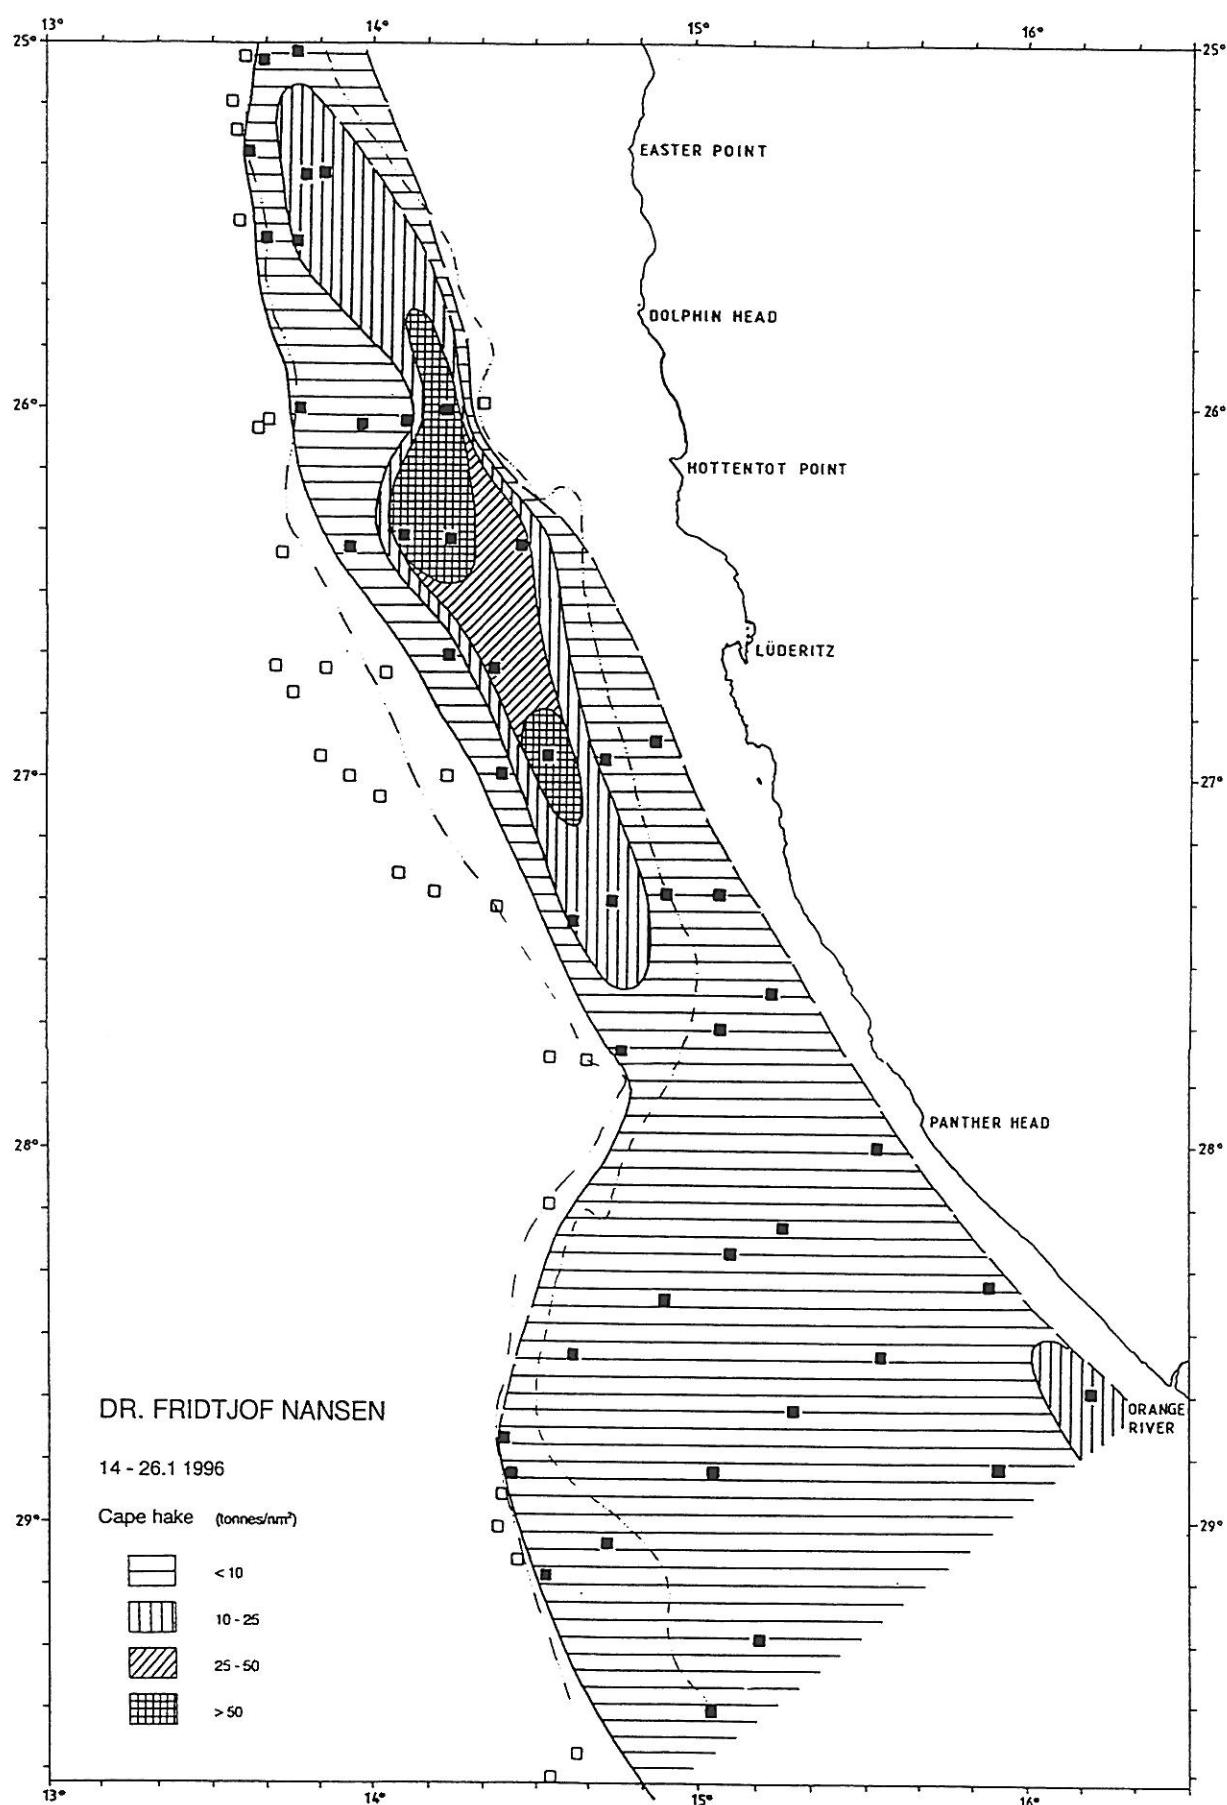

Figure 8 Orange River to Francis Bay. Distribution of Cape hake. Empty squares indicate stations where Cape hake was not caught.

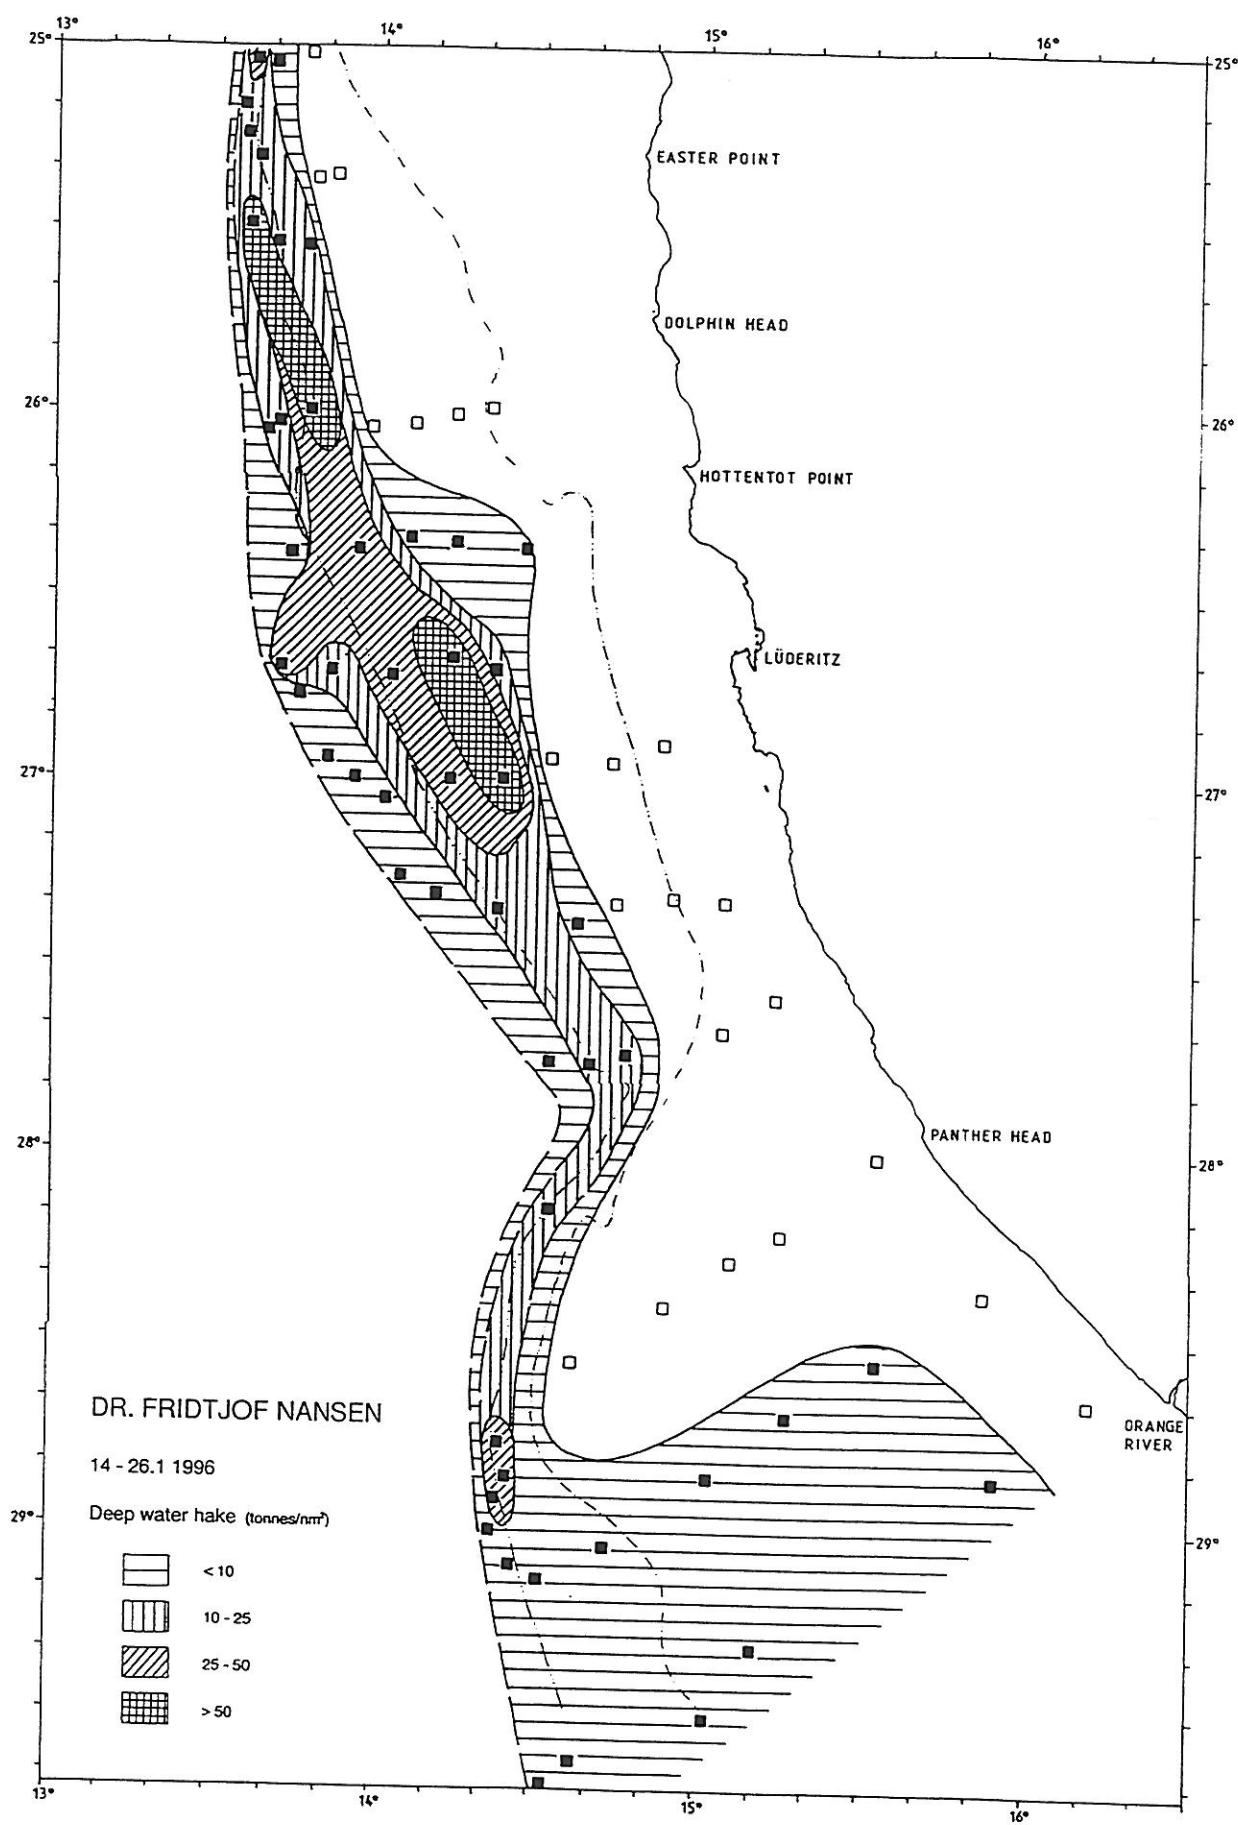

Figure 9 Orange River to St. Francis Bay. Distribution of deep water hake. Empty squares indicate stations where deep water hake was not caught.

The size compositions of the Cape hake from pooled samples weighted by catch rates are shown for each region by depth ranges in Annex I. There is, as, usual an increase of size with depth. A length frequency analysis to identify cohorts in the stock, was performed in the same way as during the three previous surveys. The results are shown in Table 5.

Table 5 Southern Region. Cape hake. Estimated age-cohorts from optimized length distributions.					
Year class	Mean length	Sigma	Fraction of all fish	Population million N	Biomass 1 000 t
1995	15.6	1.8	0.06	72	2
1994	24.0	2.5	0.46	486	45
1993	29.0	2.8	0.41	443	72
older			0.07	79	50

The data on 1995 year-class are not representative as the fish is still mostly in a pelagic state, and has been included here only for the completeness of the total biomass estimate. The main part of the biomass is made up of the 1994 and 1993 year-class, which has not yet started to recruit to the fisheries. The fishable biomass in the region is estimated to 50 thousand tonnes and 76 million fish. This is a not significant reduction from 61 thousand tonnes in May 1995.

Results from a length frequency analysis on the deep water hake is shown in Table 6. The fishable part of the stock in the region is estimated to about 114 thousand tonnes and 165 million fish. This constitutes a substantial increase in biomass from 65 thousand tonnes fishable in May 1995.

Table 6 Southern Region. Deep water hake. Estimated age-cohorts from optimized length distributions.					
Year class	Mean length	Sigma	Fraction of all fish	Population million N	Biomass 1 000 t
1994	14.9	2.0	0.3	292	7
1993	23.3	2.0	0.145	142	12
1992	30.7	3.0	0.395	380	76
older			0.16	144	107

3.3 CENTRAL REGION, ST. FRANCIS BAY TO AMBROSE BAY

Table 7 shows the catch composition for the shelf and the slope by main groups. The mean catch rates for both hakes combined have increased both on the shelf and on the slope since the last survey. The increase is 100% (from 375 to 780 kg/h) on the shelf and 75% (from 305 to 535 kg/h) on the slope. The on-shelf catches is mainly represented by young fish, so called 'non-fishable' biomass. For monk, the catch rates in the more shallow depth range have increased about five times from 1.3 to 6.8 kg/h, while beyond 250m bottom depth the mean rates have increased 3 times from 7.7 to 23 kg/h.

Table 7 Central Region. Catch rates by main groups in swept area bottom trawl hauls, kg/hour.

MEAN		535.3	23.0	5.4	0.2	14.3	437.3

The density index by depth ranges of the two hake species is shown in Table 8. The density for the Cape hake has been of a declining trend in all depth zones during two surveys after May 1994 and show now signs of recovery on the shelf and in the 250-350m zone, the main habitat for the adult Cape hake in the Central Region. The catch rates from the two last surveys are:

	May -95	Feb. -96
100-250m	390	800
250-350	300	430
350-450	45	20

This is still below the level prior to 1994. However, there is a seasonal trend in the abundance of Cape hake in the region with a bottom in the late summer season. The present increase is thus against the seasonal trend and could indicate stronger recovery.

The density of deep water hake in the Central Region continues to rise in its main depth zones, where it is now at record high levels. Compared to May 1995 the figures are:

	May -95	Feb. -96
250-350	60	70
350-450	230	610
450-550	250	560
550-650	285	190

It is interesting to note that the deep water hake now exceeds the Cape hake in catch rates beyond 250 m bottom depth.

Table 8 Central Region. Depth distribution of the two hake species. Mean densities in tonnes/nm ² and mean catch rates kg/hour.

Deep w. hake					
Density		2.3	20.2	18.7	6.4
Catch rate		70	610	560	190
No. of hauls	23	20	14	8	9

Figure 10 shows the distribution of Cape hake over this region. Compared with the previous survey the picture of a recovering trend is confirmed and high density clusters of young hake are observed on the shelf. The deep water hake (Figure 11) continues to increase northwards in its preferred depth range and are now forming bands of moderately high to high densities across the whole regional map.

The biomass estimate of Cape hake for the Central Region based on post stratification is 145 thousand tonnes (Table 9). As seen in the table this represents the first brake in the downward trend of biomass estimates in the region that started in November 1992. The recovery is however still moderate. The estimate on the deep water hake is 73 thousand tonnes, about 80% increase since May 1995, prolonging the trend of biomass increase that has persisted in the course of the survey programme since 1990

Table 9 Central Region. Estimates of total biomass by surveys, 1 000 tonnes.		
Year/Survey	Cape hake	Deep water hake
90/1	180	4
90/3	219	6
91/1	150	6
91/2	302	13
92/1	261	15
92/2	542	15
93/1	280	12
93/2	280	20
94/1	225	30
94/2	160	30
94/4	112	16
95/1	105	40
96/1	145	73

(Table 9). The 95% confidence limits on the estimates are $\pm 15\%$ on the Cape hake and $\pm 22\%$ on the deep water hake.

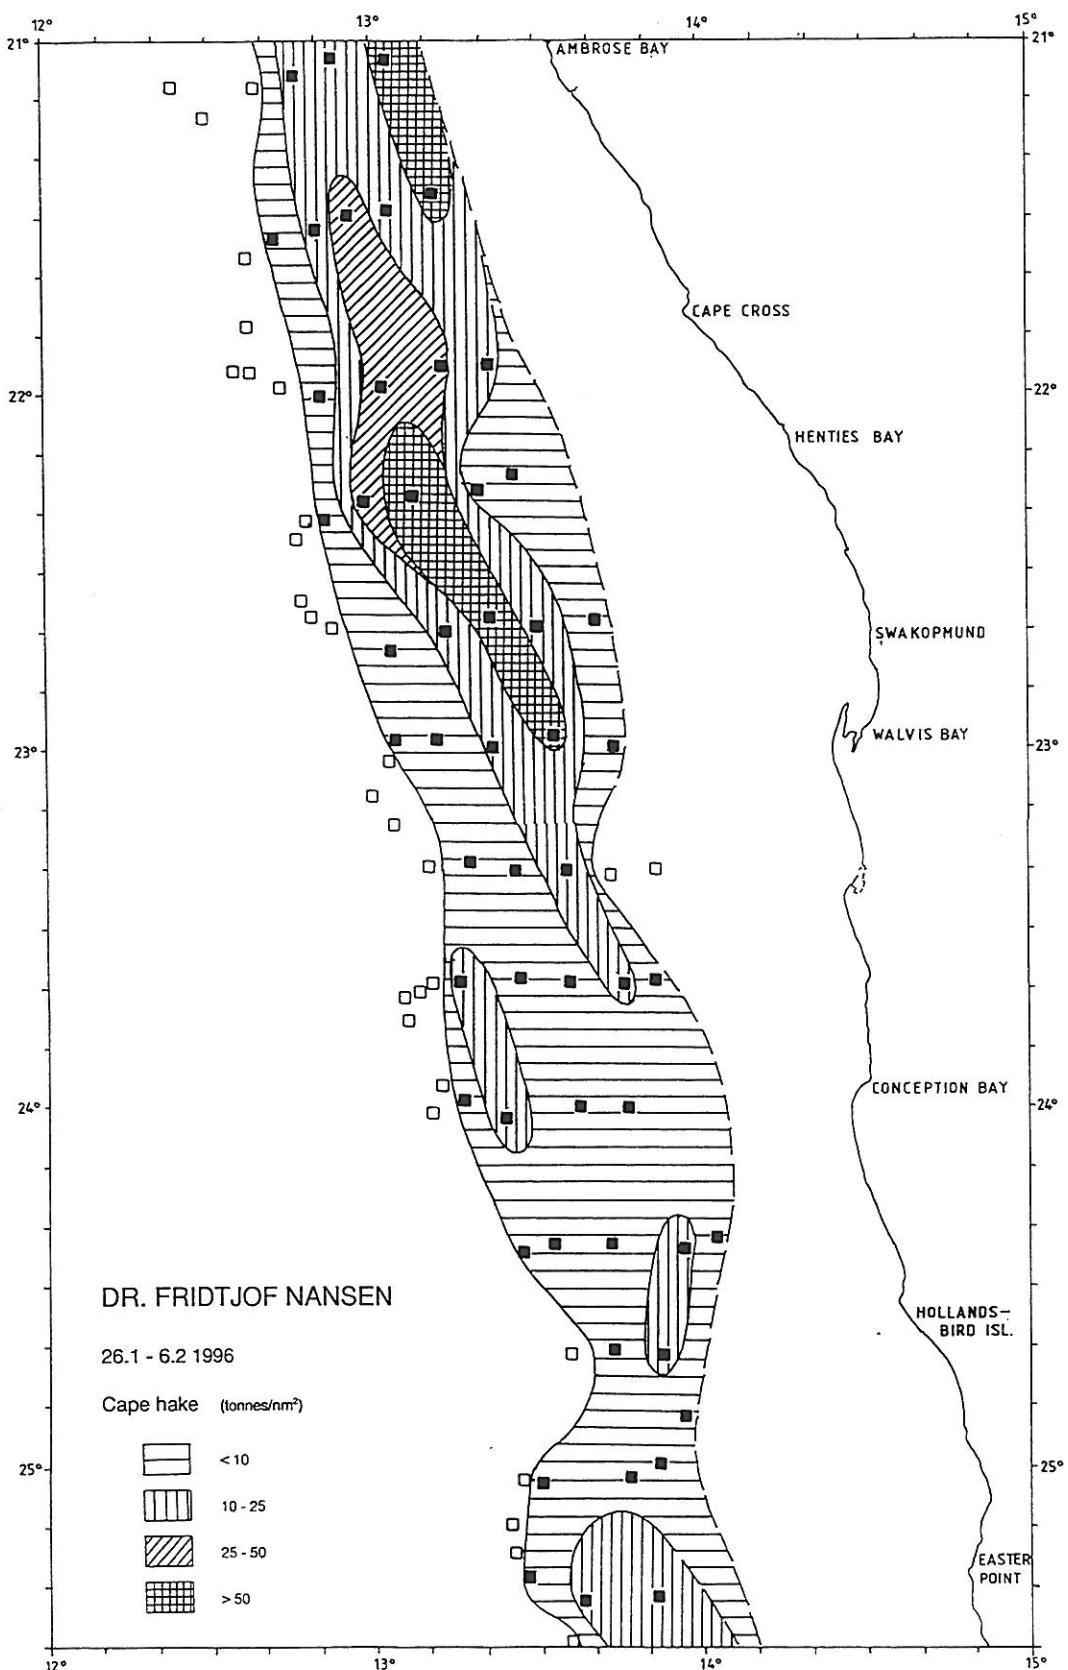

Figure 10

St. Francis Bay to Ambrose Bay. Distribution of Cape hake. Empty squares indicate stations where Cape hake was not caught.

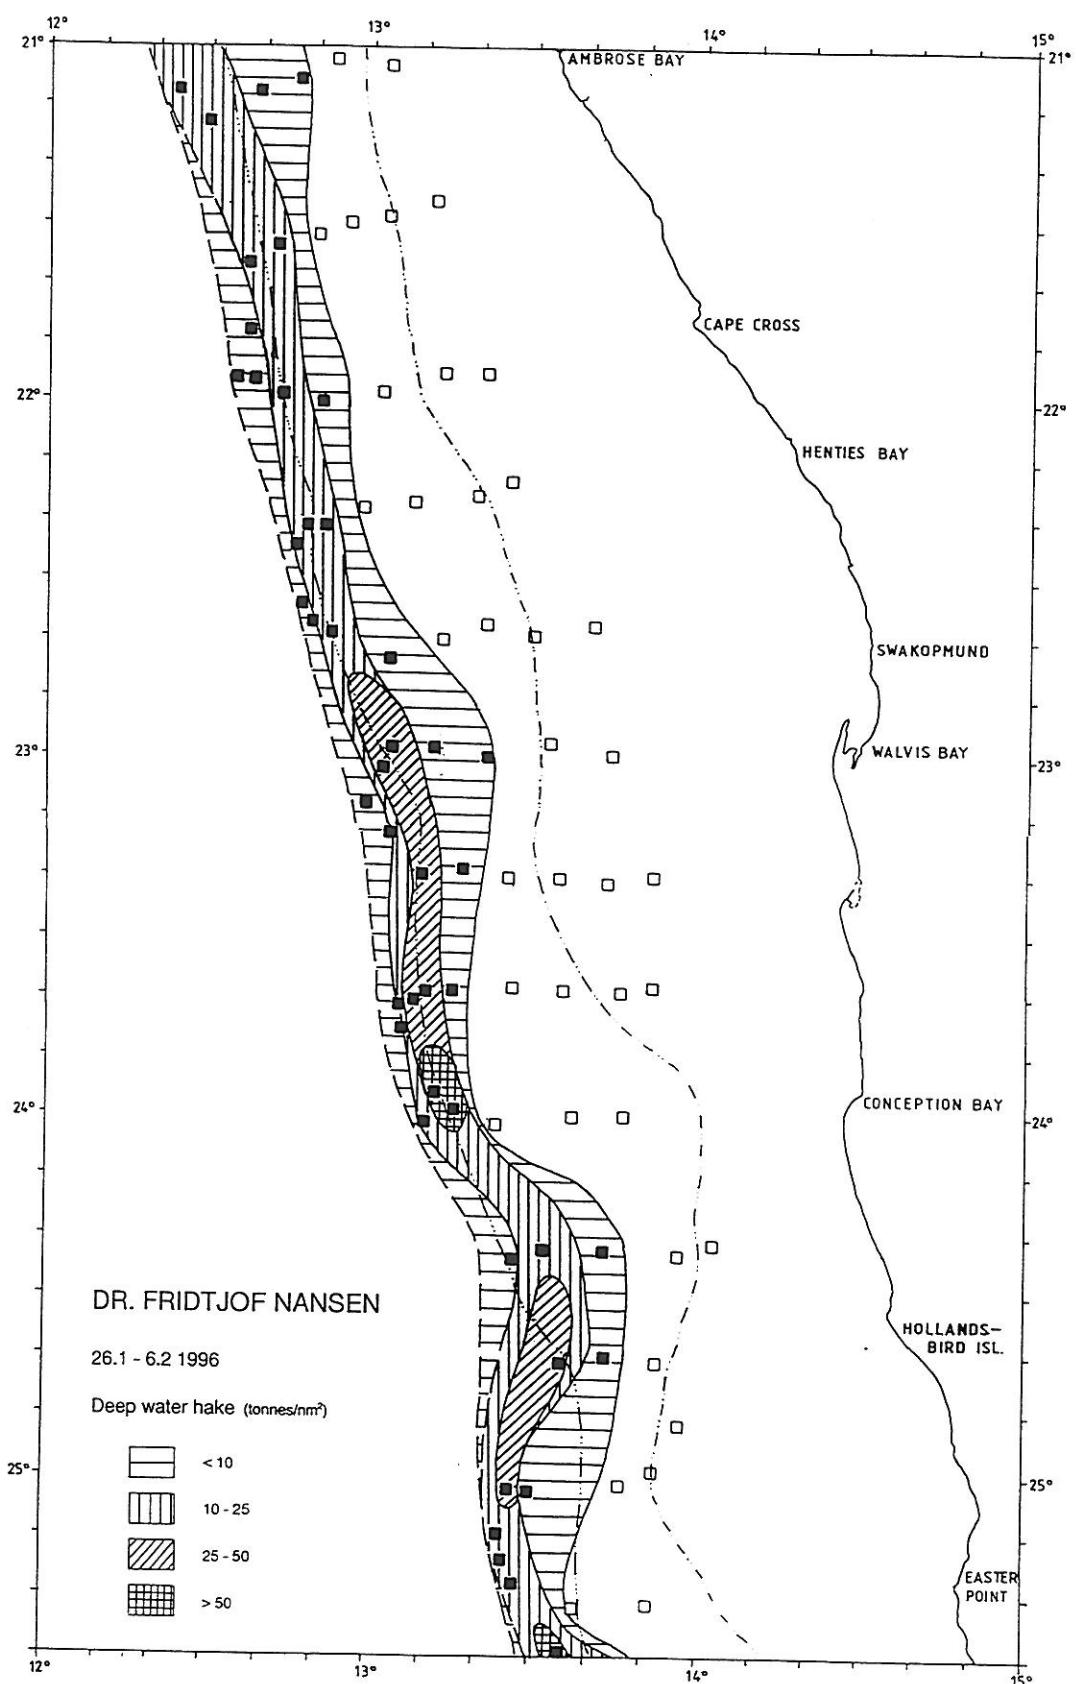

Figure 11 St. Francis Bay to Ambrose Bay. Distribution of deep water hake. Empty squares indicate stations where Cape hake was not caught.

The results from a cohort analysis on the length distribution are shown in Table 10.

Table 10 Central Region. Cape hake. Estimated age-cohorts from optimized length distributions.					
Year class	Mean length	Sigma	Fraction of all fish	Population million N	Biomass 1 000 t
1995	12	1.5	0.055	70	1
1994	23	2.0	0.830	1031	87
1993	31	3.0	0.078	94	18
older			0.037	48	39

The 1994 year-class dominates the fish population with 83% of the number and 60% of the biomass. The fishable part of the population is 41 000 tonnes and 54 mill fish. This represents a reduction in the fishable biomass by 13 000 tonnes since the last survey and the present figure is new record low in the course of the survey programme. On the other hand the recruits or the non-fishable biomass has increased from 51 000 to 104 000 tonnes.

Results from the length frequency analysis for the deep water hake are shown in Table 11. In this population the fishable biomass is 56 000 tonnes and is 76% of the total biomass. This is a 24 000 tonnes increase from the last survey and has more than replaced the loss of adult Cape hake in the same period.

Table 11 Central Region. Deep water hake. Estimated age-cohorts from optimized length distributions.					
Year class	Mean length	Sigma	Fraction of all fish	Population million N	Biomass 1 000 t
1994	24.0	2.0	0.03	6	0.6
1993	30.4	3.0	0.49	79	17
older			0.47	77	56

3.4 NORTHERN REGION, AMBROSE BAY TO CUNENE RIVER

Table 12 shows the catch rates by main groups for the shelf and slope separately. The mean rate for hakes shows a slight increase in the shallower zone and in the deeper zone the rate has decreased by 25% compared to last survey. The average catch rate for monk in the slope is about 50% compared to the previous survey, and on the shelf the species was only caught on one station.

Table 12 Northern Region. Catch rates by main groups in swept area bottom trawl hauls, kg/hour.

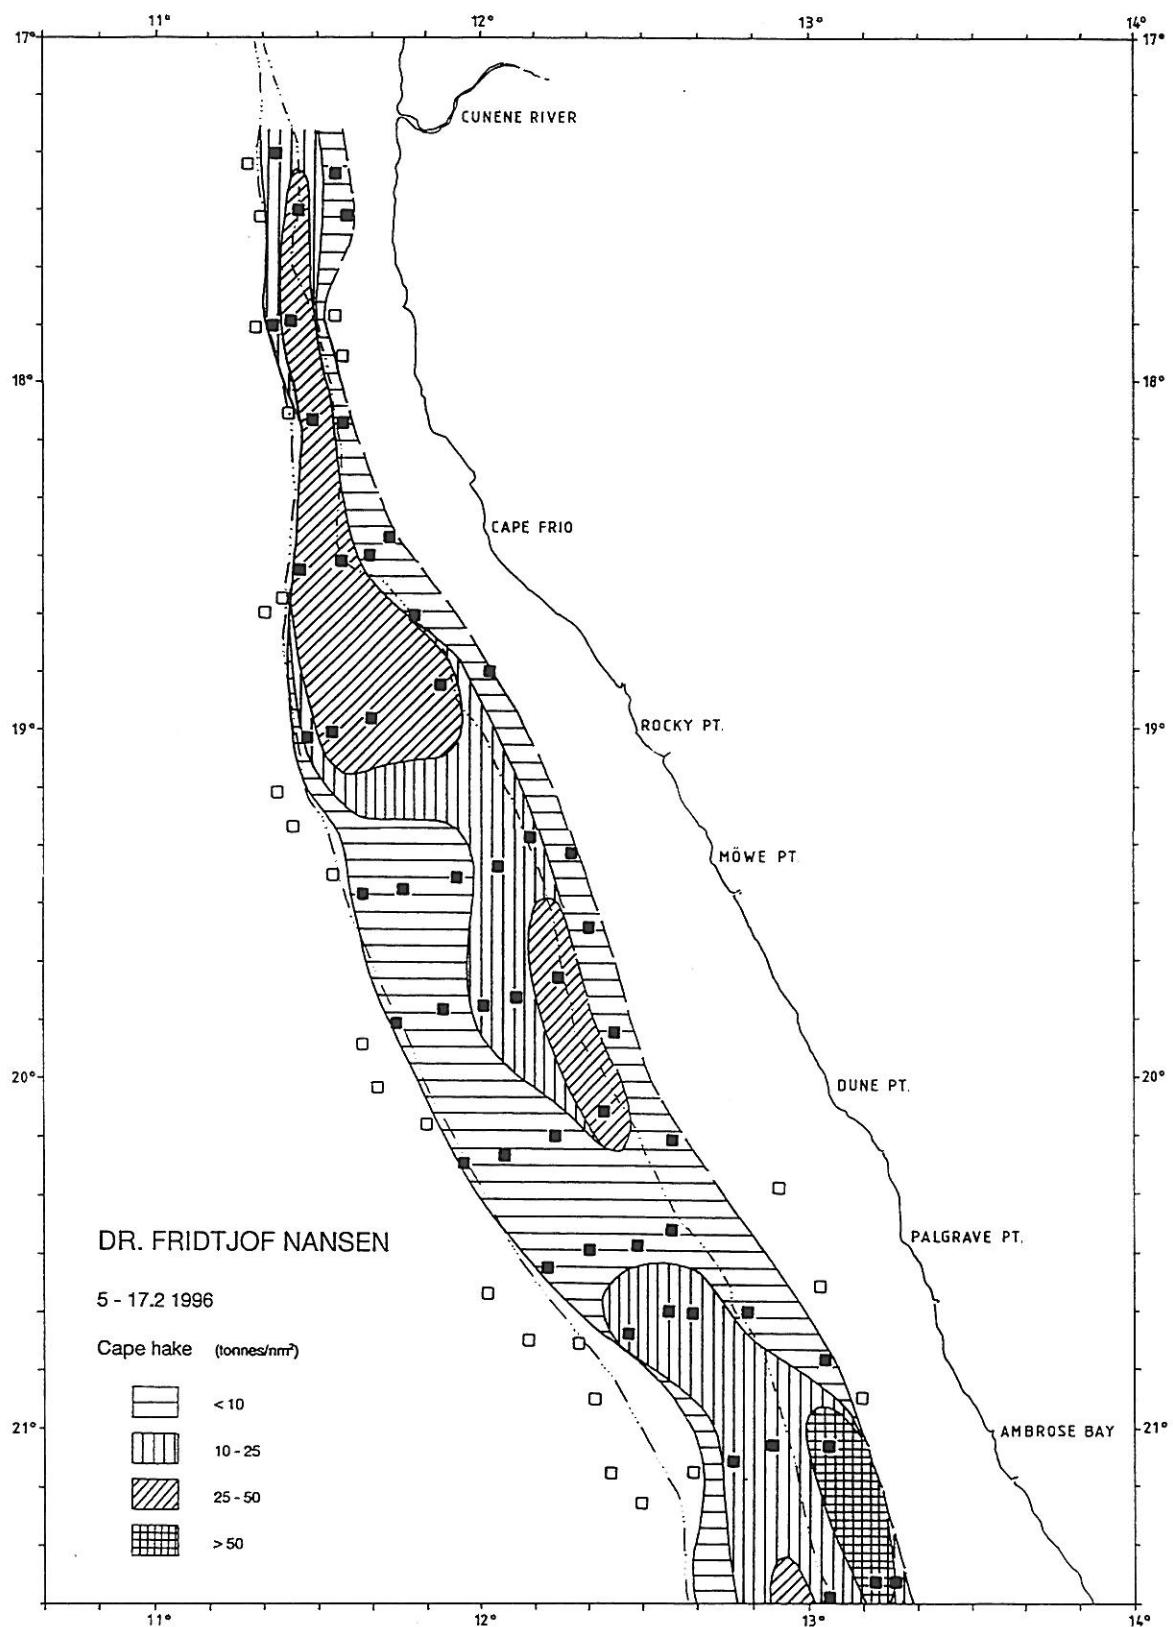

Figure 12 Ambrose Bay to Cunene River. Distribution of Cape hake. Empty squares indicate stations where Cape hake was not caught.

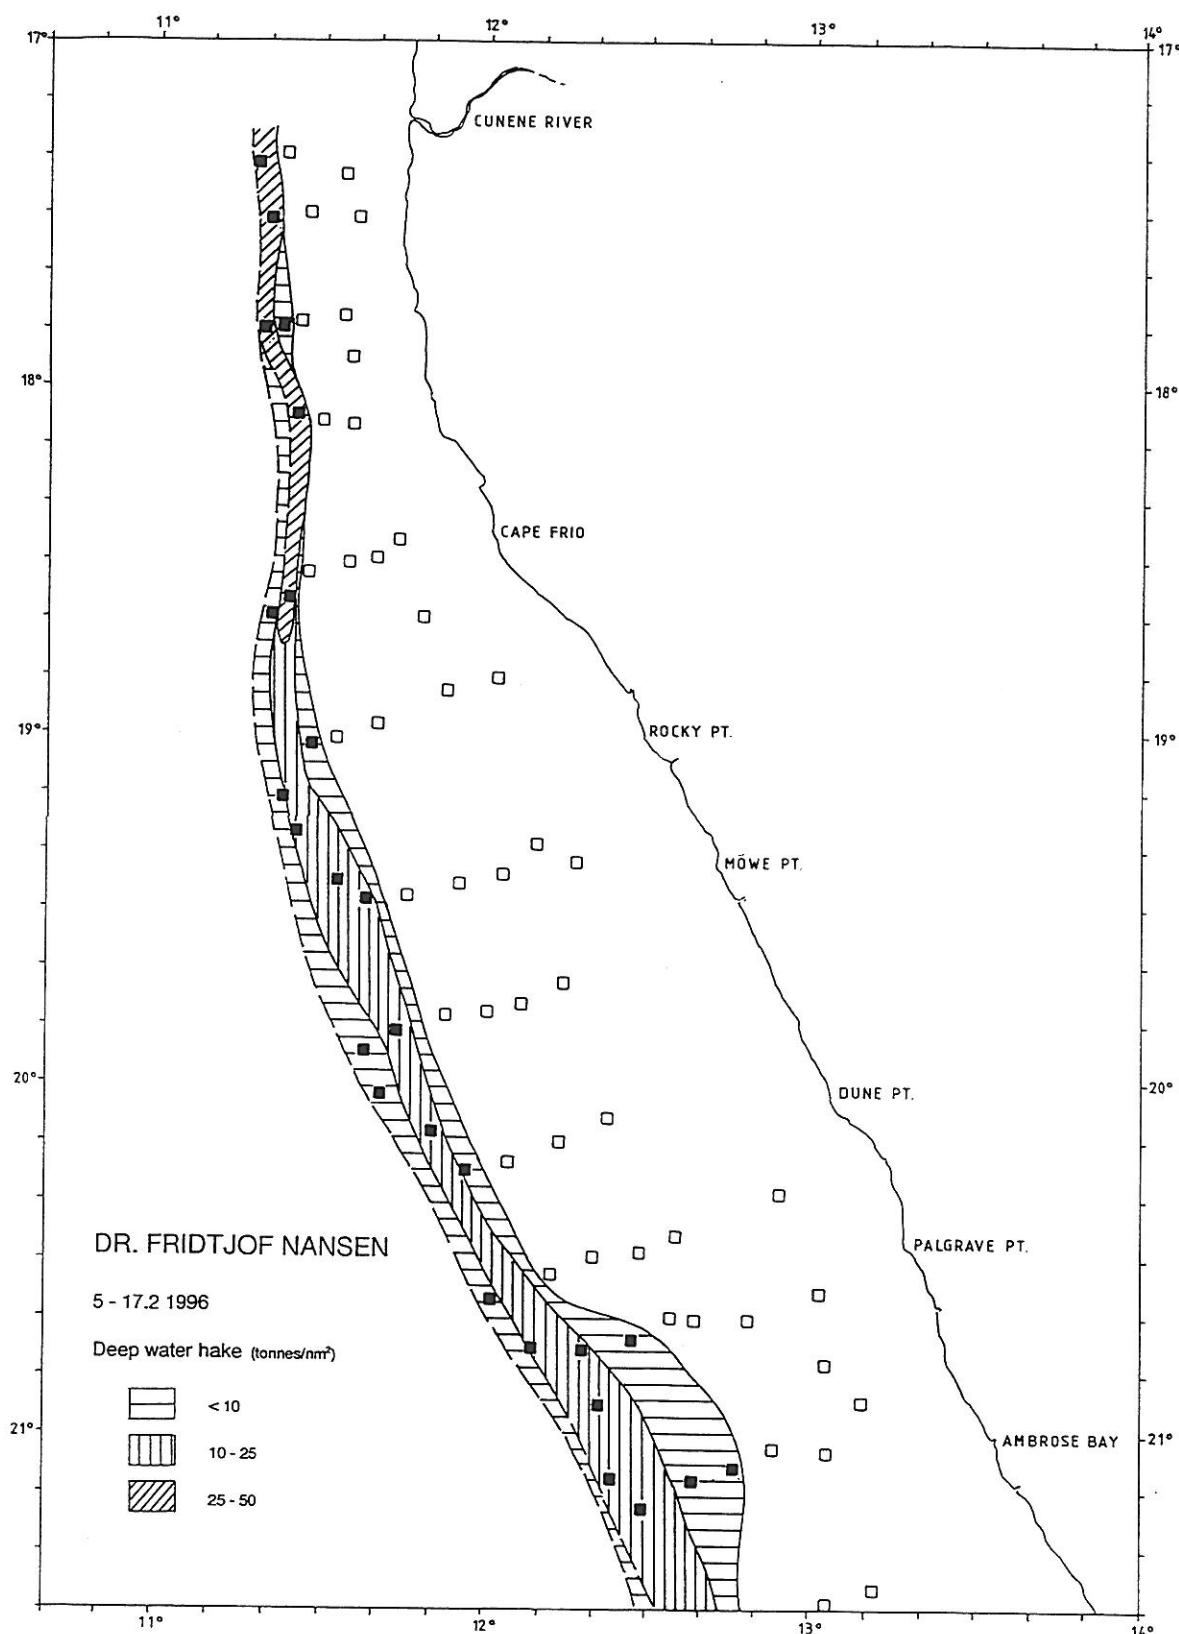

Figure 13

Ambrose Bay to Cunene River. Distribution of deep water hake. Empty squares indicate stations where deep water hake was not caught.

Figure 12 shows the distribution of Cape hake in the northern region by levels of density calculated from the catch rates and with correction for fish in mid-water. Extensive high-density aggregations beyond 50 tonnes/nm² were found between the Cunene and Möve Point during the previous survey. During the last survey these densities have been reduced. The deep water hake is forming a band of aggregation around 500m bottom depth and shows a marked increase (Figure 13) in these aggregations compared to the previous survey.

The depth distribution of the two hake species based on catch rates converted to densities is shown in Table 13. For Cape hake there was an increase in the 100-250 m depth zone and decrease between 250 and 450m. This corresponds generally to increase of young fish and decrease of older fish beyond 30 cm. The densities of deep water hake increased 180% in the 350-450 m zone and about 45% between 450 and 550m.

Table 13 Northern Region. Depth distribution of the two hake species. Mean densities in tonnes/nm ² and mean catch rates kg/hour.					
	100-250m	250-350m	350-450m	450-550m	550-650m

Deep w. hake Density Catch rate		0.6 17	9.4 280	18.9 570	5.2 155
No. of hauls	26	19	8	6	6

Biomass estimates give a total of 132 000 tonnes of Cape hake and 31 000 tonnes of deep water hake (Table 14). For the Cape hake this represents an increase of 15 000 tonnes since the last survey. The increase is associated with young fish (see below). The deep water hake increased from 24 to 31 thousand tonnes. The 95% confidence limits on the estimates are ±40% on the Cape hake and ±22% on the deep water hake.

Table 14 Northern Region. Estimates of total biomass by surveys, 1 000 tonnes.

94/2	130	14
94/4	87	9
95/2	117	24
96/1	132	31

* + hake in the mid-water

The size compositions of the two hake species are shown in Annex I. A cohort analysis was done on the two hake species and the results are shown in Tables 15 and 16. The so called 'fishable biomass' in the Northern Region, representing fish of 36 cm and larger, constitutes 88 000 tonnes and 150 mill. fish. This is close to the 93 000 tonnes fishable biomass estimated from the previous survey. The non-fishable biomass has increased about 15 000 tonnes in the same period.

Table 15 Northern Region. Cape hake. Estimated age-cohorts.					
Year class	Mean length	Sigma	Fraction of all fish	Population million N	Biomass 1 000 t
1995	13	1.5	0.01	4	
1994?	27.4	2.5	0.45	191	26
1993	34.0	3.5	0.29	125	33
older			0.251	108	73

A similar analysis on the older deep water hake in the region is shown in Table 16. The estimated fishable biomass of deep water hake is 28 thousand tonnes, an increase of 7000 tonnes since May 1995.

Table 16 Northern Region. Deep water hake. Estimated age-cohorts.

1992	40.7	3.8	0.73	48	21
1991+				8	7

CHAPTER 4 CONSIDERATIONS ON THE SURVEY RESULTS

Survey effort

The present survey is the 13th in a series started in early 1990, covering the distribution of the hake stocks over the whole Namibian shelf. Figure 14 shows the effort spent in these investigations. The survey was done in 38 days, including 3 days for intercalibration with "Africana".

Mid-water behaviour of the hake can cause problems for the trawl survey methodology. However, improved acoustic technology has made it possible to establish a technique that can reduce the effect of this behaviour on the estimates. In previous surveys (1993 to Jan. 1994) the pelagic behaviour may have caused some underestimate in the biomass, especially in the Northern Region. During the recent survey the average acoustic corrections during day time were 3%, 4% and 9% for the southern, central and northern regions respectively. The corresponding figures for the night hauls are 56%, 33% and 43%. Night hauls are usually carried out only on the

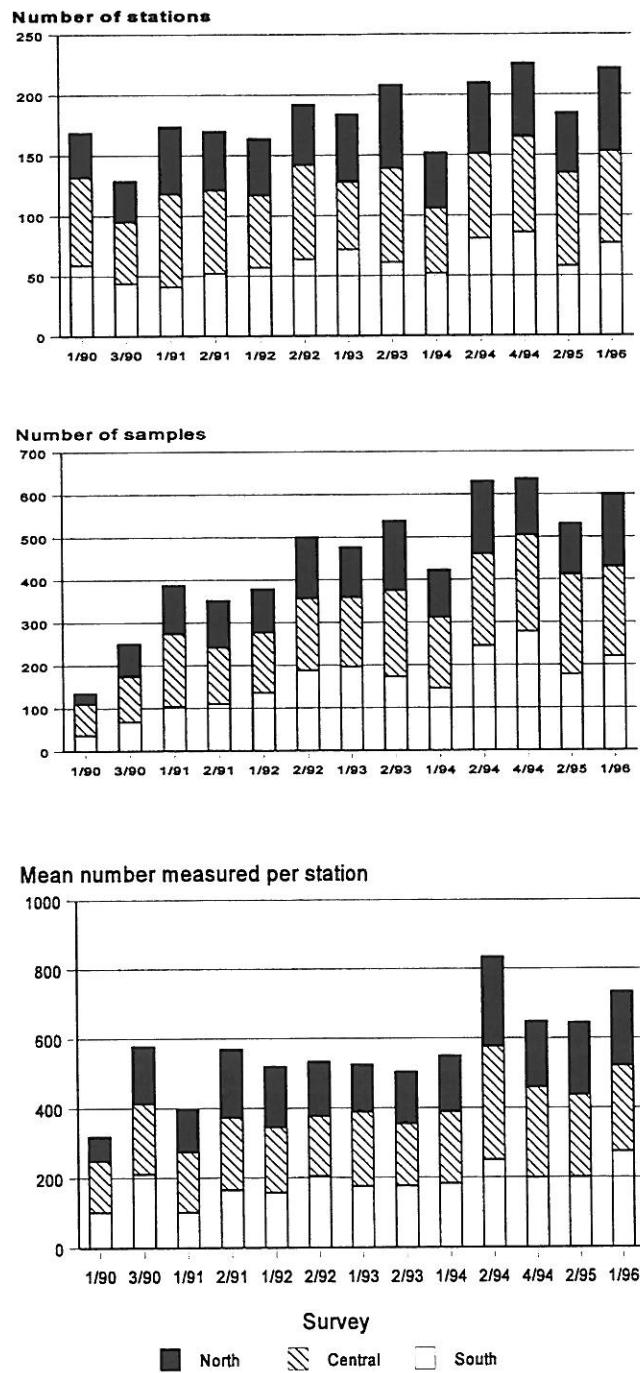

Figure 14 Hake survey effort 1990-94. a) Number of trawl stations by regions; b) Number of length frequency samples by regions; c) Mean number of fish in length sample.

fringes of the fish distributions where the densities are low. Thus the correction in absolute terms is small as well. The pelagic behaviour of the hake did not constitute a major problem when assessing the stock, and there are no signs that major aggregations of hake have avoided acoustic detection. Two stations with extraordinary high catches in the southern region and one similar station in the north give high contributions to the biomass estimates of young fish and therefore also lower the precision on these estimates.

Catch per unit effort

A summary of the estimates of the mean density of the hakes by depth stratum is shown in Figure 15. The densities in the shallow ranges 100-250 m mainly reflect the strength of the young fish, 2-3 years of age, that inhabit this zone. In the Central Region and Northern Region there are a partial recovery from the exceptionally low levels observed in May 1995. However, the densities in the recruiting biomass of Cape hake are still below the normal of the preceding 6 years. The structure of the recruit biomass will be discussed below. In the deeper waters, in the 250 -350m depth range there is an increase of densities of Cape hake in the Southern Region and a decrease in the Central and Northern Regions. This is partly explained by seasonal migration towards the south in the summer season, and Figure 15 shows a cyclic pattern in the densities where the south is in opposite phase to the Central and North Regions.

The deep water hake shows a rising trend in all three regions in its main habitat, the 350-550m depth range on the slope, Figure 15. It could be that, because of bad recruitment from the Cape hake in the later years, the deep water hake is now gradually filling in from south to the niche left open. This will be the subject of a separate study.

Observed catch rates in fisheries will only to a certain extent reflect the densities observed through surveys. As the fishing fleet tends to work on the highest fish aggregations, the so called hot spots, CPUE data tend to overestimate the mean densities in a fish population. As an example, during the recent survey a major aggregation of trawler fleet was observed northwest of Lüderitz, on one of the hot spots observed and measured by the trawl survey.

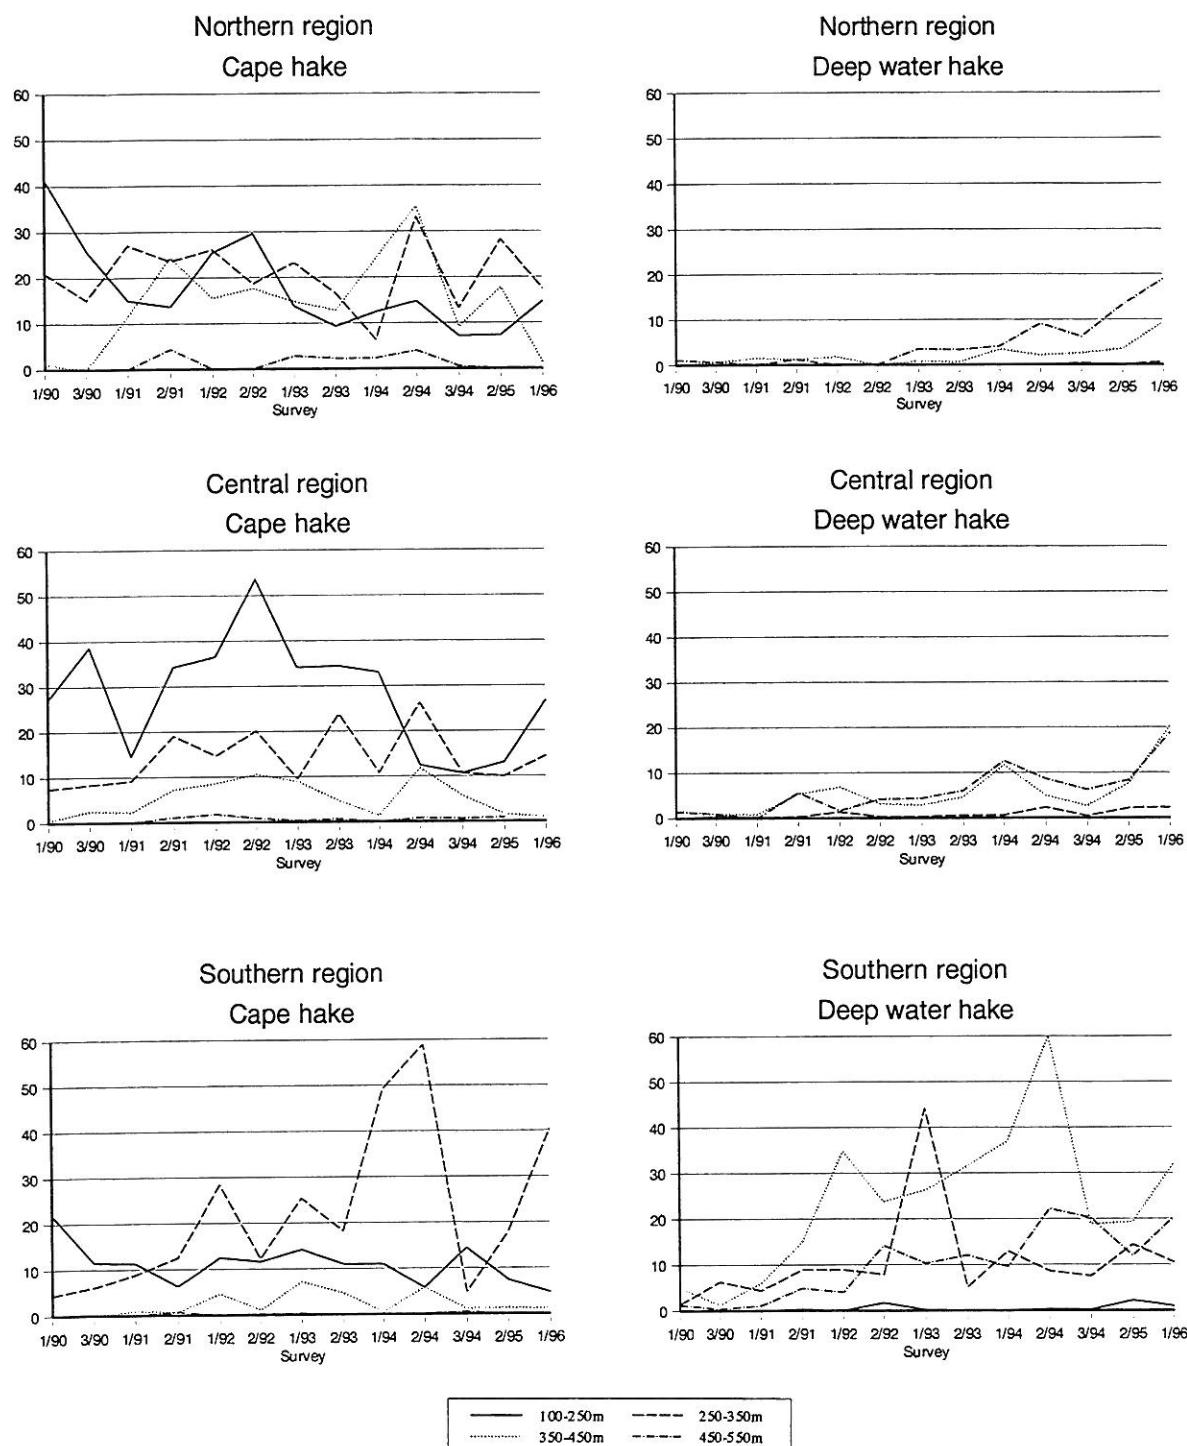

Figure 15 Estimated mean densities in depth strata by surveys. Mean densities in tonnes/nm². Biomass estimates.

Table 17 and Figure 16 give a summary of the biomass estimates for the two hake stocks by regions and surveys since the beginning of the survey programme in 1990. Table 17 and the accompanying Figure 16 have been revised since the previous survey. During the first year of the programme a simple method for pooling the length samples was applied, and this has underrepresented the small and relative abundant small sized fish in the length based estimates. As a consequence the share of the fishable biomass in the total biomass was overestimated in the first two surveys. This has now been corrected and all the estimates are made by the same method.

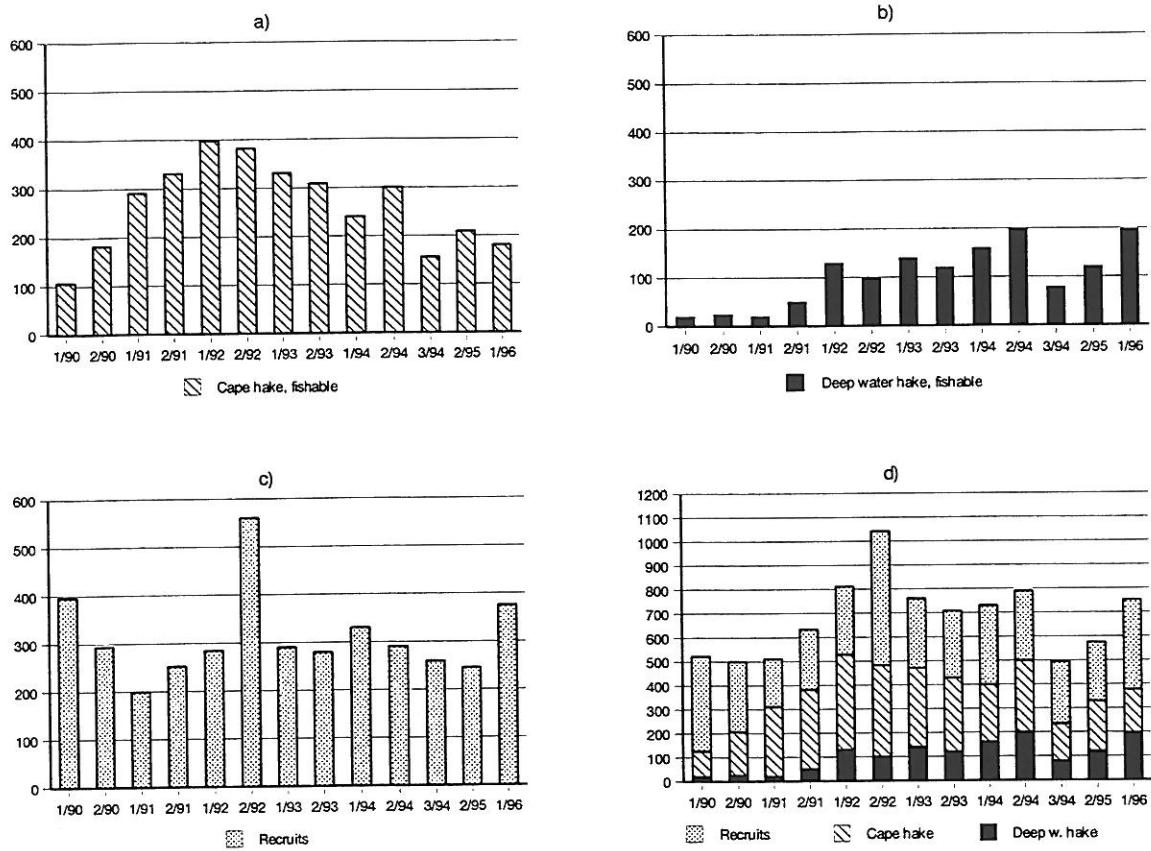

Figure 16 Trends in biomass estimates: a) Cape hake, 'fishable stock', b) deep water hake, 'fishable stock', c) recruits ('non-fishable' biomass) and d) total hake in Namibia. Thousand tonnes.

Figure 16d shows the development in the total hake biomass. There has been a trend of decline since late 1992 until late 1994. The two last surveys show an increasing trend and since November 1994 the total biomass has increased from its record low 235 000 tonnes to the recent 380 000 tonnes. The main part of the increase, however, is associated with growth in adult deep water hake (+118 000t) and recruits of both species (+73 000 and +43 000) while the Cape hake has only recovered 25 000 tonnes from its 155 thousand tonnes in late 1994. One has to look back to 1990 to find comparable figures on the state of the fishable biomass of Cape hake (Figure 16a). Figure 16b shows that the

deep water hake has now reached a level of 200 000 tonnes and the species is now surpassing the Cape hake in abundance of the adult stock in Namibia.

Geographic shift in the fishable biomass

Figure 17 shows the development of the relative share of the fishable biomass of Cape hake in the regions for the last six years. The figure shows that the Northern Region during the last survey holds 49% of the fishable biomass and that the Northern and Southern Regions share of the Cape hake biomass has increased at the expense of the Central Region.

Recruitment potential

The recruitment to the stock of Cape hake can be estimated from the numerical abundance of the 1.5-2 year old fish. November is usually the month when one first time through trawl surveys can estimate the strength of the year-class born the previous year, as it has then settled on bottom during the previous months. The estimates for the 1994 year-class, based on the current survey data, are shown in Table 20 together with previous observations. A 'normal' recruitment level after two years seems to be around 2 billion fish \pm 200 million (Table 18). The 1994 year-class is at present with 1.5 billion fish 25% below a 'normal' recruitment level.

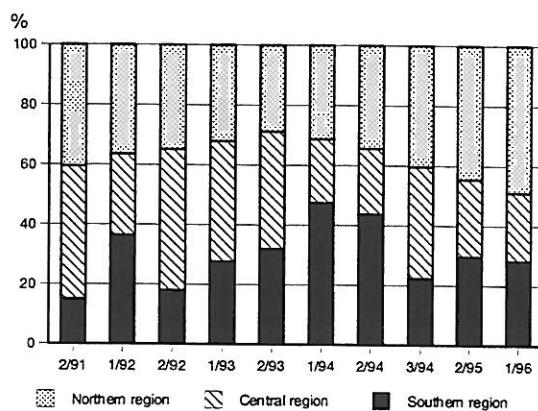

Figure 17 Relative regional share of fishable biomass of Cape hake 1991-94.

Table 18 Estimates of strength of recent yearclasses of Cape hake. Cohort population numbers at about two years of age for the groups assumed to have been spawned in 1988, 1989, 1990, 1991 and 1992. Millions of fish.

Yearclass	1988	1989	1990	1991	1991	1991	1992	1992	1993	1993	1994
Southern region	980	100	300	990	670	390	250	2 308	1 730	510	485
Central region	1 320	170	1 620	3 500	1 230	1 370	1 880	3 017	490	430	1 030
Northern region	10	10	240	440	270	130	70	5	190	80	0
Total	2 205	515	1 518	4 930	2 170	1 890	2 200	1 235	2 410	1 020	1 515
Survey/Year	1/90	1/91	1/92	2/92	1/93	2/93	1/94	2/94	3/94	1/95	1/96

The 1993 year-class was estimated to 1 billion fish in May 1995, and is now reduced to 0.8 billion fish. Even if the cohort analysis technique is considered rough and indicative the figures indicate low natural mortality on the 1993 year-class during 1995 and a small fraction of the year-class has already entered into the fishable biomass.

The recruit biomass for both species combined, Figure 16c and Table 17, has been in a slight downward trend during 1994 and 1995 but show now promising signs with about 50% increase in biomass since May 1995, from 245 to 375 thousand tonnes. In Table 19 the recruits are splitted by the age classes identified through the cohort analysis. The table shows that 220 000 tonnes or 75% of the recruit biomass belong to the cohort that is now 2.5 years, the 1993 year-class. This fish is now in the 27 to 37 cm length range and will recruit to the fishable biomass during the coming year. This indicates a relative strong growth potential in the fishable biomass on short term. In a 2-year perspective, recruitment will depend on the life history of the 1994 year-class, which at present is below normal. However it may, if given good survival conditions as the 1993 year-class has met, give important contributions to the rebuilding of the parent stock.

Management considerations

The parent stock of the Cape hake is at a critically low level and measures should be taken to protect the stock and to build it to a higher level. There are signs that a relative high number of recruits will enter into the fishable biomass during the coming year and this offers an opportunity to increase the size of the parent stock.

The deep water hake continue to expand in Namibia and is filling in to the ecological niche previously occupied by the Cape hake. Most of the stock of deep water hake is of adult size and it is believed that most of the fish is recruited from south. It should be considered to introduce a management practice that would direct more of the fishing towards the deep water hake. Fishing in areas or depth zones with less than maximum catch rates are also recommended. Fishing beyond 350m in selected areas will mainly give deep water hake and protect the more shallow Cape hake.

5 COMPARATIVE FISHING EXPERIMENTS WITH R/V "AFRICANA"

5.1 DESCRIPTION OF METHODS

"Dr. Fridtjof Nansen" arrived at the rendez-vous position (S 29°, E 16°) at 08:00 h on 16 January. After a planning meeting on board "Africana" the intercalibration started with parallel hauls 1.5-2 cables apart. Both vessels were maintaining normal trawling procedures respectively, according to Table 20.

Table 20. Tow parameters during the intercalibration						
	Tow time	Speed	Door spread	Wing spread	Vertical opening	Warp strapping*
"Africana"	20 min.	3.5 knots	>100 m	~27 m	~2 m	No
"Nansen"	20 min.	3.0 knots	~ 51 m	~ 21 m	~5.6 m	Yes

*Strapping is restricting door spread through the application of a 10 m long rope of which one end is attached to a mark on the port warp (on "Nansen" 130 m in front of the door) through a snap lock, and the other end is running free on the other warp with a purse seine ring with a roller which can be opened to be hooked on to the warp.

"Africana" was using heavy warps with diameter 32 mm, while "Nansen" was using lighter 26 mm warps. "Nansen" generally shot more warp than "Africana". The "Africana" trawl was rigged without a groundgear, with only a heavy groundrope ("sabb"), while "Nansen" used a gear with low profile cylinders and rather few discs. "Africana" used 25 mm cod end mesh size while "Nansen" used 22 mm. Scanmar sensors were used on both ships to monitor door spread and vertical opening.

The intercalibrations lasted for three days. Personnel for intercalibration of fish classification and measurement were exchanged the last two days. Altogether, 19 parallel hauls were made, all between 120 and 200 m. Two hauls were discarded due to one problem on "Africana" and one problem on "Nansen", giving a total of 17 usable pairs of hauls. Seven of these were made on the last day. Unfortunately "Africana" had a computer crash this day, and the data of these seven hauls were lost. This report will therefore deal with the first ten hauls.

All catch figures were corrected for swept area. "Africana's" swept area was calculated with the following formula:

$$A_A = V * 1852 * T / 60 * S_A$$

where A_A is swept area in m^2 , V is ship speed, T is tow time (bottom time) in minutes and S_A is wing spread in meters. The ship speed was set at 3.5 kn for all hauls. A wing spread of 27.86 m was used for all hauls. This was the average wing spread for "Africana" in the 1995 intercalibration.

"Nansen's" swept area was calculated with the following formula:

$$A_N = D * 1852 * S_N$$

where A_N is swept area in m^2 , D is towed distance measured from GPS plotter track, and S_N is wing spread. A wing spread of 21 m was used for all hauls, also according to the 1995 intercalibrations. Swept area corrections were made according to following formula:

$$N_A = N * 1000 / A$$

where N_A is the number of fish per 1000 m^2 , N is the number of fish in question, and A is swept area either of "Africana" or "Nansen". Fish weights were corrected in the same manner.

A two tailed Student's t-test for paired samples was used for all comparisons of catch numbers, catch weights and length groups except for the length group of hake from 0-10 cm where a Wilcoxon non-parametric paired sample test was used.

5.2 RESULTS AND DISCUSSION

Swept area

Normally in considering swept area of trawl gear, e.g. in cod assessment, bridle length and door spread are very important parameters. As hakes were the target species of this investigation, the herding of these species have to be considered in particular. From experiments carried out on the "Nansen" in 1995 it seems that the herding efficiency of doors/bridles is far less for hake than for e.g. cod. In experiments with a triple trawl for *Nephrops* in the North Sea it was observed that catches of silver hake (*Merluccius merluccius*) were evenly distributed between the three parallel trawls, while more herdable species like blue whiting were strongly overrepresented in the middle trawl. Monkfish (*Lophius piscatorius*) were evenly distributed like the hake (HUSE, unpublished). Although the 1995 results were to some degree internally conflicting, the overall impression was

that herding of hake by bridles, doors and sand clouds is of little importance. In the hake assessment carried out by the "Nansen", a sweeping width of 18.5 m has been applied. This is even less than the observed wing spread, based on the assumption that there may be some avoidance and possibly mesh selection in the wing area, and hardly any herding by bridles, sand cloud or doors.

In conclusion we have for this intercalibration chosen to adapt a swept width equal to wing spread as herding effect of bridles, doors and sand cloud may be of little importance for hake. In view of the implications of this aspect for trawl based assessment, herding efficiency should, however, be further elucidated through comprehensive trials at varying water depths and times of day, preferably with two ships using the same gear and procedures.

Hake

Results for hake are given in Figure 18 and in Annex V, Table 1.

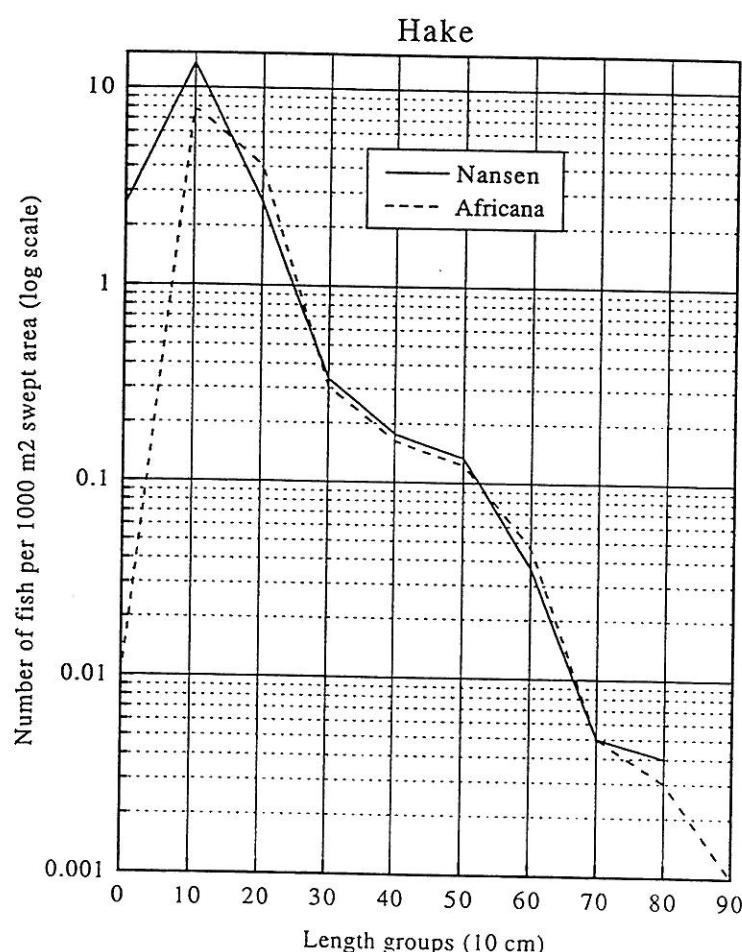

Figure 18 Numbers of hake per 1000 m² in 10 cm length groups. 0=0-10 cm,---,90=90-100 cm. Logarithmic Y-axis.

“Nansen” catches were significantly higher than “Africana” catches for 0-10 cm and 10-20 cm hake. For 0-10 cm this was probably due to mesh selection related to the difference in cod-end mesh size. For 10-20 cm this is less likely. The difference is more likely to be related to mesh selection further ahead in the trawl, or to escapement over the low opening “Africana” trawl. For other length groups there were no significant differences in catches. On the contrary the two vessels had quite coinciding catch rates for larger hake. But it should be noted that the catches of larger hake were smaller than one could have wanted in an exercise like this.

Other species

Catches of monk and gurnard were considered as indicators of bottom contact of the two trawls. “Africana” had significantly higher catches of numbers of gurnards (Annex V, Table 2) and weights of monk (Annex V, Table 2) than “Nansen”. Differences in numbers of monk and weights of gurnards were not significant. These results indicate that the “Africana” trawl, with its ground rope as opposed to “Nansen”’s ground gear probably is superior in catching species normally resting on the bottom. The result could perhaps also be ascribed to the much wider door spread and potentially larger sweeping area of the “Africana”, but for slow swimming species like monk and gurnard this is not a likely explanation.

There were no significant differences in catches of horse mackerel or kingklip. “Nansen” caught somewhat more horse mackerel than “Africana” (Annex V, Table 3) and “Africana” caught slightly more kingklip than “Nansen” (Annex V, Table 3). The higher opening of the “Nansen” trawl might have been expected to catch more horse mackerel than the low opening “Africana” trawl, and the high bottom contact “Africana” trawl might have been expected to catch more kingklip than the “Nansen” trawl, which are indeed also the catch tendencies indicated. However, with the relatively small number of hauls no significant differences were demonstrated as mentioned above.

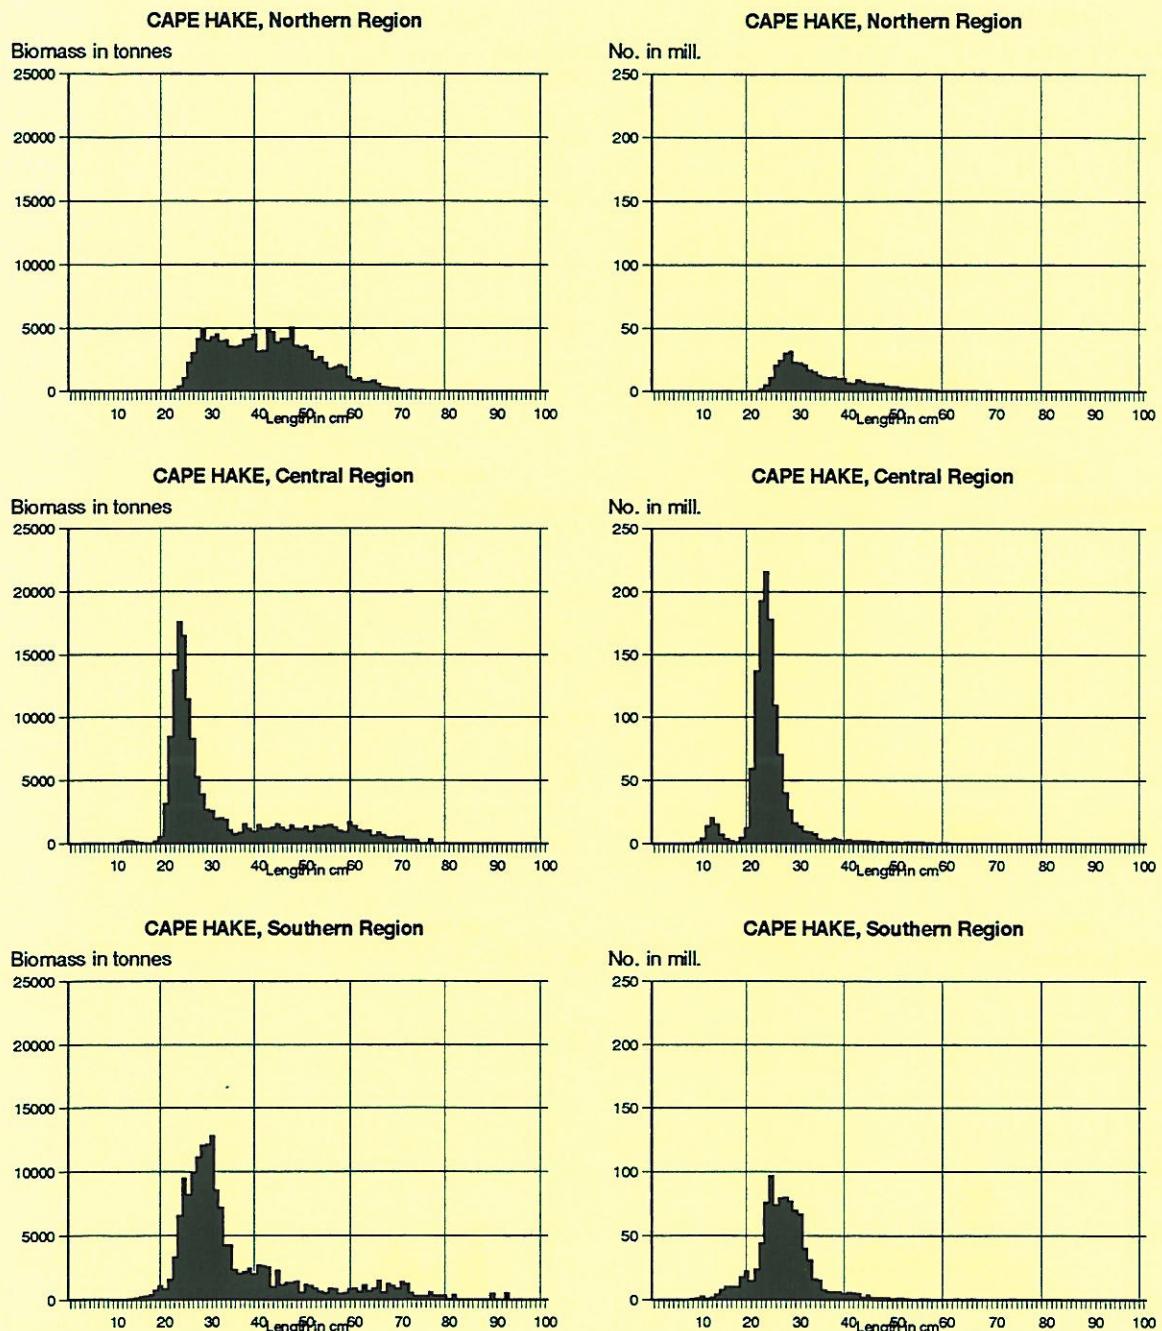

Total biomass

“Africana” had significantly higher biomass per unit of swept area than “Nansen” (“Africana” higher in eight out of ten tows, Annex V, Table 2). The average total biomass for “Africana” was 5.80 kg/1000 m², and 3.34 kg/1000 m² for “Nansen”. This was mostly due to higher catches of large sharks and skates, probably caused by the wider door spread of the “Africana”.

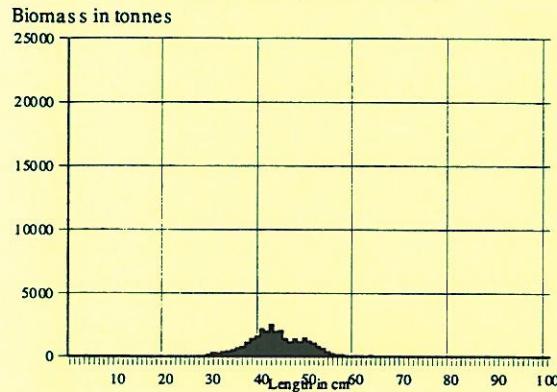

Trawl height

For the three last hauls “Africana” tested out a trawl which was supposed to give higher opening than their standard trawl. This expectancy did not materialize. The cause could be that the “Africana” trawl rigging seems to induce a high and unrestricted door spread with a large sweeping angle. This could reduce trawl height, and could also cause variations in trawl parameters with depth. One way of getting around this potential problem is to use warp strapping (see above, under Table 1). In the “Nansen” rigging this is used 130 m in front of the doors, giving a stable door spread of 51 m with 50 m bridles, and a stable height of 5.6 m, regardless of depth/warp length.

Annex IV Instruments and fishing gear used

Acoustic instruments

The SIMRAD EK500/38 KHZ scientific sounder was used during the survey for estimation of fish density. The EK500 has a built- in digital echo integrator, but the Bergen Echo Integrator system (BEI) was used throughout the survey. The details of the instrument settings are as follows:

Transceiver settings:

Bandwidth	Wide (3.8 KHz)
Pulse length	Medium (1 ms)
Max Power	2000 Watt
Sv Transducer gain	27.8 dB
Ts Transducer gain	28.1 dB

Printer settings:

Range	0 - 100 or 0 - 250 m
TVG	20 log R
TS Colour min	- 50 dB
Sv Colour min	- 64 dB

An ES38B with a 6.8° -3dB beamwith transducer was used for integration.

A calibration experiment using a standard copper sphere, performed in Baia dos Tigres 23/2 1994 gave the following results: Sv Transducer gain 27.8 dB, Ts Transducer gain 28.1 dB.

Glossary:

Sv Transducer gain: Peak transducer gain assumed during computation of volume backscattering strength.

Ts Transducer gain: Peak transducer gain assumed during computation of target strength.

Ts Colour min: Lower limit of colour scale relative to target strength.

Sv Colour min: Lower limit of colour scale relative to volume back scattering.

Hydrography

Conductivity, temperature, density and oxygen were sampled regularly at CTD stations with a Seabird CTD-sonde. The salinity was calculated by a computer.

Fishing gear

The vessel has two different sized 'Åkrahamn' pelagic trawls and one Gisund super bottom trawl. Only the bottom trawl was used during the survey.

The bottom trawl has a headline of 31m, footrope 47m and 20mm meshsize in the codend with an innernet of 10mm meshsize. The estimated headline height is 5m and distance between the wings during towing about 18m. The trawl is equipped with a 12" rubber bobbins gear and 7.8m², 1670kg 'Tyborøn' trawl doors. The sweeps are 40m long.

The following drawings show the size of these trawls.

Bottom trawl: High opening shrimp and fish trawl with net headline 31m (floatline), foot-rope 47m, gear with 12 cm diameter roller disks, 40 m sweeps, estimated headline height 6m and distance between wings during towing 18-20m.

Annex V Comparative fishing "Africana" and "Dr. Fridtjof Nansen" 16-18 January 1996.

Table 1. Trawl station numbers and numbers of hake per 1000 m² swept area in different length groups. Mean values and p-values for T-tests are also given.
