

NORAD - FAO/UNDP PROJECT GLO 92/013

CRUISE REPORTS DR. FRIDTJOF NANSEN

SURVEYS OF THE FISH RESOURCES OF NAMIBIA

Cruise Report No 1/97

Surveys of the hake stocks

10 January - 20 February 1997

Ministry of Fisheries & Marine Resources
Swakopmund
Republic of Namibia

Institute of Marine Research
Bergen
Norway

The surveys with the DR. FRIDTJOF NANSEN are part of a wider development programme in fishery research and management sponsored by the Norwegian Agency for Development Cooperation (NORAD), and co-ordinated in co-operation with the Food and Agriculture Organization of the United Nations (FAO), and the United Nations Development Programme (UNDP). The programme in Namibia is organized and planned under agreements between NORAD, Namibian authorities and the Institute of Marine Research (IMR), Bergen, Norway. Its execution is the responsibility of IMR, in cooperation with the Ministry of Fisheries & Marine Resources of Namibia.

The following surveys were carried out in Namibia:

Survey	1/90	25 January to 19 March 1990
"	2/90	27 May to 20 June 1990
"	3/90	11 September to 6 October 1990
"	1/91	25 January to 23 March 1991
"	2/91	23 October to 16 December 1991
"	1/92	23 April to 21 June 1992
"	2/92	20 October to 16 December 1992
"	1/93	20 January to 19 March 1993
"	2/93	21 April to 25 May 1993
"	1/94	19 January to 21 February 1994*

CHAPTER 1 INTRODUCTION

1.1 General objectives

Following an offer from NORAD extended through FAO and UNDP, an agreement was reached in Windhoek in January 1990 between the UNDP Resident Representative and Namibian authorities for the execution of a programme of surveys of the fish resources of the Namibian shelf with the R/V DR. FRIDTJOF NANSEN.

The main objectives were agreed as follows:

To describe the distribution, composition and abundance of the most important fish resources. Small pelagic fish, including horse mackerel, pilchard and anchovy would be investigated by the acoustic integration method combined with sampling with mid-water and bottom trawls. A swept area trawl survey programme would be used for the demersal stocks. All catches would be sampled by species, weight and numbers, including biological sampling of the commercially important stocks.

To carry out environmental studies including recording of surface temperature on a continuous basis and hydrographic sampling on a series of fixed profiles.

1.2 Objectives of survey 1/1997

The main objectives were to continue to monitor the abundance, geographic distribution and size composition of the hake stocks within the Namibian EEZ in order to identify trends in hake stock abundance. This information is an important basis for fishery management, and is particularly useful in the effort to achieve the aim set by the 1990 White Paper of rebuilding the depleted hake stocks. As secondary objectives, less abundant, but commercially important species like monk, sole and kingklip will be studied in detail as these species form a natural bycatch of a hake survey in Namibia. As part of the hake research, environmental parameters were continuously recorded in order to improve knowledge on the influence of the environment on the distribution of the hake stocks.

The acoustic system was used to estimate the relative importance of mid-water occurrences of hake and therefore improve the biomass estimate. The survey design for the swept-area trawl programme was based on a semi-random distribution of hauls along regular transects

perpendicular to the coast. The transect distance was normally between 20 and 30 NM. On the slope the stations were laid out to cover the depth ranges of the two hake species. The on-shelf stations were laid out 10 to 15 NM apart until the zero line of hake distribution was found. Information from the acoustic system was also used in this process. Biomass estimates of hake were based on post stratification by depth and density aggregations.

Additional objectives were to carry out comparative fishing with R/V AFRICANA and with two local freezer trawlers ('Katima' and 'Echelar'). The aim of comparative fishing with AFRICANA was to establish conversion factors to facilitate comparison between hake distribution and abundance in South Africa and Namibia. Specific aims of trawl intercalibration with commercial freezer trawlers included: (a) investigate viability of using trawlers in conducting hake biomass surveys (b) compare the catch rates of the research vessel with those of the trawlers (c) involve the fishing industry in the assessment of hake resources.

1.3 Participation

The scientific staff consisted of:

From Namibia:

Liza BURMEISTER (1-20/2), Michael EVENSON (10-31/1), Johnny GAMATHAM (10/1-20/2), Hashali HAMUKUAYA (1-20/2), Antonette HEITA (1-21/2), Sheila HEYMANS (10-21/1), Teophilus KAIRUA (10-31/1), Ekkehard KLINGELHOEFFER (10-31/1), Heinrich LESCH (10-31/1), Heidrun PLARRE (1-20/2), Peter SCHNEIDER (1-20/2), Justina SHIFIDI (10-31/1), Malakia SHIMANDA (10/1-20/2).

From Norway:

Oddgeir ALVHEIM (10/1-20/2), Ingve FJELDSTAD (10/1-20/2), Ingvar HUSE (10/1-5/2), Tore MØRK (10/1-20/2), Tore STRØMME (31/1-20/2), Jan Tore ØVREDAL (31/1-5/2).

1.4 Narrative

The course tracks with the positions of the fishing and hydrographic stations are shown in Figures 1 a-c.

The vessel left Walvis Bay on the afternoon of 10 January and steamed south to commence the work between Lüderitz and Orange River. Trawling shallower than 300 m was preferably carried out during daylight hours, while the deeper stations on the slope were carried out during dark. CTD-stations were taken on almost every trawl station in order to map the environmental conditions in relation to fish distribution. On 13 January the vessel met with AFRICANA for a three day trawl intercalibration exercise. After comparative fishing with AFRICANA the normal survey work commenced from Orange River. On 21 January the ship called at Lüderitz Bay to set ashore Sheila Heymans. On 31 January the ship called at Walvis Bay for crew change, having covered the area south of Walvis Bay.

DR. FRIDTJOF NANSEN departed the port of Walvis Bay for the second leg of the survey on 1 February accompanied by two freezer trawlers, ‘Katima’ and ‘Echelar’ for comparative fishing. Comparative fishing started on the morning of 2 February, trawling with ‘Katima’ in a tandem until 5 February. Meanwhile, ‘Echelar’ was busy with gear selectivity experiments, and only participated in the comparative fishing for one day. After comparative fishing, DR. FRIDTJOF NANSEN continued the work northwards following the standard grid pattern. The northern border was reached on 15 February and on the way south, four transects that were skipped on the trip north, were filled in. Arrival in Walvis Bay was on 20 February.

The weather conditions were generally rough in the south, with wind forces ranging from 5 to 37 knots (average of 21 knots) but the work continued uninterrupted. On the northern leg the weather conditions were favourable.

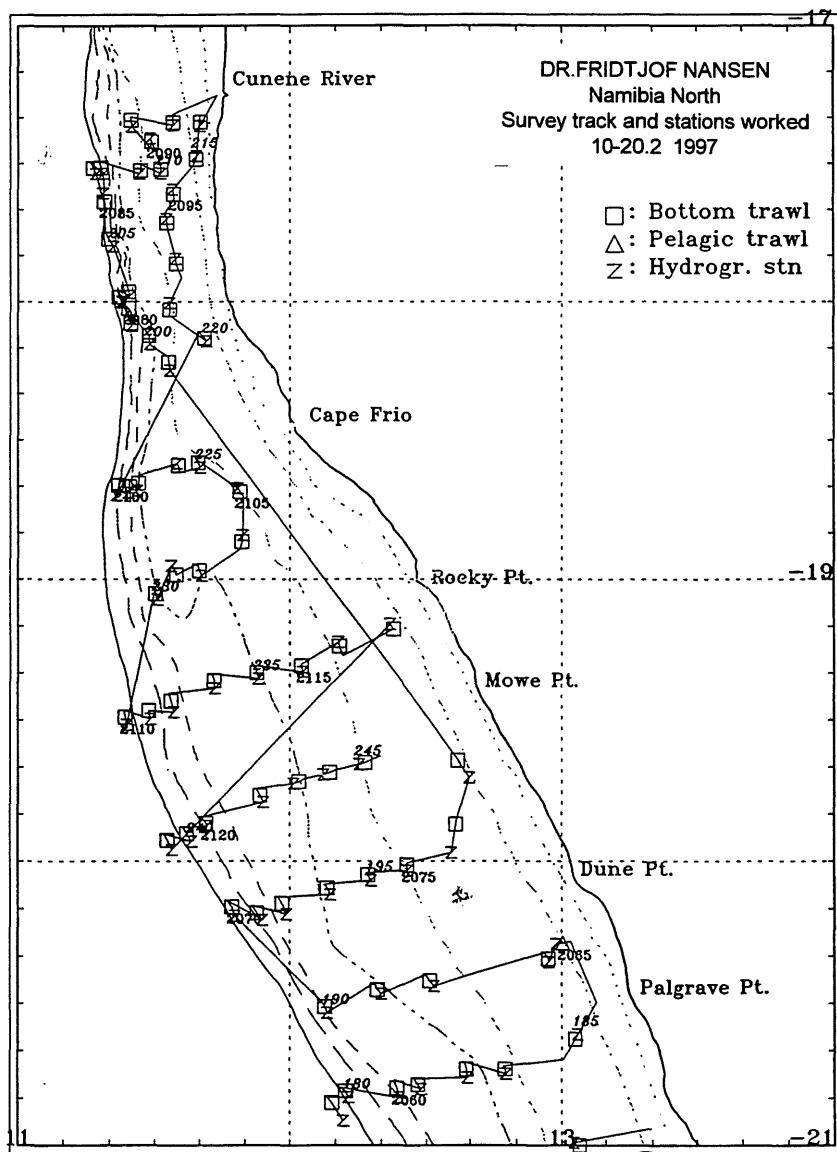

Figure 1c Northern region (Ambrose Bay to Cunene River). Course tracks, fishing stations and hydrographic stations.

CHAPTER 2 HYDROGRAPHY

Strong southerly winds prevailed during the first part of the survey until Walvis Bay, whereafter a calm period occurred. Figure 2 shows the wind conditions along the survey track.

Sea temperatures at 5 m depth were recorded continuously along the cruise track and are shown in Figures 3a-c. Six hydrographic sections were collected at the standard locations and are shown in Figures 4a-c. The surface temperatures showed cooled upwelled waters in much of the southern region and intense upwelling in the Lüderitz area. A relatively weak upwelling was observed in the Cunene area.

Dissolved oxygen (DO) was recorded at all fishing stations (Figures 5a-c), to observe its influence on the hake distribution. In this survey, the bottom water was rich in DO over the whole southern and most of the central region. However, the entire North shelf was covered with oxygen-deficient water masses ($\leq 0.5 \text{ ml/l}$). Oxygen may be a prerequisite for successful settlement of the pre-recruit hakes on the bottom. The oceanographic conditions appeared to be favourable and the system active as compared to the events of 1994. Juvenile hake were observed in abundance, covering much of the central region, but these were not quantified.

As during previous surveys, the maps showing DO near the bottom are overlaid with the distribution maps of the Cape hake, Figures 6a-c. They show that only minor fractions of the hake distributions are found in waters of less than $0.25 \text{ ml O}_2/\text{l}$, while the fish seem to sustain levels just beyond that limit.

CHAPTER 3 RESULTS OF THE ACOUSTIC AND TRAWL SURVEY

3.1 Introduction

In the trawl survey programme all catches were sampled for composition in weights and numbers by species. The bottom trawl had a headline of 31 m (float line), a footrope of 47 m, headline height of 5-6 m and a distance between the wings during towing of about 21 m. All trawl hauls were monitored by SCANMAR trawl sensors (trawl depth, headline height and distance between the doors). This technology allows to determine with improved accuracy the actual time the trawl is on the bottom. A constraining rope was attached between the warps, 130 m in front of the doors. This constraining rope keeps the distance between the doors constant irrespective of trawl depth. For conversion of catch rates to fish densities the area between the wings is assumed to be equal to the effective fishing area and the retention factor q is equal to 1. With the new vessel, starting from January 1994, a new trawl gear was introduced with smaller bobbins. This gear is expected to give better bottom contact and higher catch rates for bottom dwelling species like monk and sole. For the hake species the new gear is assumed to have no difference in performance. The trawl doors are Thyborøen 7.9 m², but the net, warp and wire dimensions are as with the former vessel (see Annex IV).

Table 1 Hakes. Frequency of observations of hake in mid-water during trawling. No. of trawl stations with swept area densities and no. of stations with observations of hake above 5 m from bottom with acoustic density estimate (tonnes/nm²).

Average acou. corr.	18.7 %	23.7 %

The length of a haul over bottom, recorded as distance trawled, was measured by log pulses from the GPS, and checked against the lengths of the traces of the hauls on the GPS plotter system.

The problem of mid-water occurrence of hake and its effect on the swept area assessments has been discussed in earlier cruise reports. As in previous investigations, off-bottom hake in mid-water constituted only a minor problem in the south and in the central area. In the north it made up an average 18% addition to the demersal biomass in the day hauls. In the night hauls the average corrections were 3%, 15% and 23% for south, central and northern region respectively (Table 1).

Fish abundance (in weights and numbers) by length groups or by cohorts are found by combining the total abundance obtained from catch records with the length distributions of the species. Length distributions in fish aggregations are obtained by pooling the length frequencies from trawl stations using the catch rates as a weighting factor, and regional length based estimates are obtained through pooling the length frequencies from these areas with the biomass of the aggregations as a weighting factor.

3.2 Southern region, Orange River to St. Francis Bay

Annex III shows the complete records of the fishing stations. Table 2 shows the catch rates of the main commercial species standardized to kg/hour for the shelf and the slope separately. For the hakes the mean catch rates on the shelf are slightly up (399 to 437 kg/hour), while in the slope they are at the same level (500 kg/hour) as during the previous survey in September 1996. Monk and kingklip show low but improved catch rates on the shelf while there is a considerable increase in the catch rates of kingklip in the slope. The catch rates of monk in the slope remained at a similar level as in October 1996.

Table 2 Southern region. Catch rates in kg/hour by main groups by swept area bottom trawl for the shelf and the slope.

Figure 7 shows the depth distribution of the two hake species based on the catch rates converted to densities. A comparison with the previous survey shows that the density for the Cape hake has increased by 20% from 9 to 11.7 tonnes/NM² in the 100-250 m depth zone, and doubled from 5.7 to 13.2 tonnes/NM² in the 250-350 m zone. Compared to previous survey, the catch rates for the deep water hake were slightly lower in all depth zones except 350-450 m.

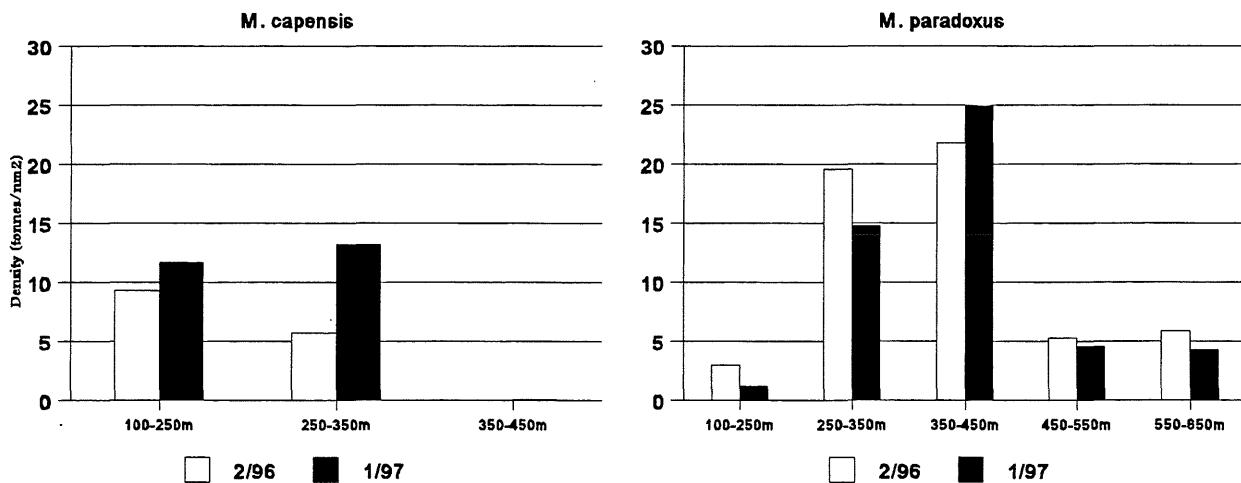

Figure 7. Southern region. Depth distribution of two hake species. Mean densities in tonnes/NM².

The distribution of the two hake species based on plots of densities by fishing stations is shown in Figures 8 and 9. These include the acoustic estimates of fish present above the 5 m bottom channel during trawling as explained above. An area of moderately higher densities (10-25 tonnes/NM²) for deep water hake was detected from Panther Head to Easter Point in which two small patches of highest concentrations were encompassed. During the previous survey, concentration of deep water hake was densest, and the area was much larger than it was now. For Cape hake, higher aggregations were found from Lüderitz to Easter Point. These aggregations were larger and more dense compared to the 96/2 survey.

Table 4 Southern region. Estimates of total biomass by surveys, 1 000 tonnes.

Year/Survey	Cape hake	Deep water hake
90/1	130	22
90/2	130	25
91/1	113	31
91/2	80	82
92/1	200	145
92/2	160	125
93/1	210	150
93/2	180	115
94/1	200	160
94/2	240	215
94/3	150	121
95/2	145	140
96/1	169	202
96/2	89	167
97/1	121	132

Biomass estimates based on a post-stratification of the densities as shown in Figures 8 and 9, gave 121 000 tonnes for the Cape hake and 132 000 tonnes for the deep water hake (Table 4), an increase of 35% for the Cape hake and a decrease of 20% for deep water hake since the previous survey. The 95% confidence limits give a range of $\pm 25\%$ on the estimate of the Cape hake and $\pm 26\%$ of the deep water hake.

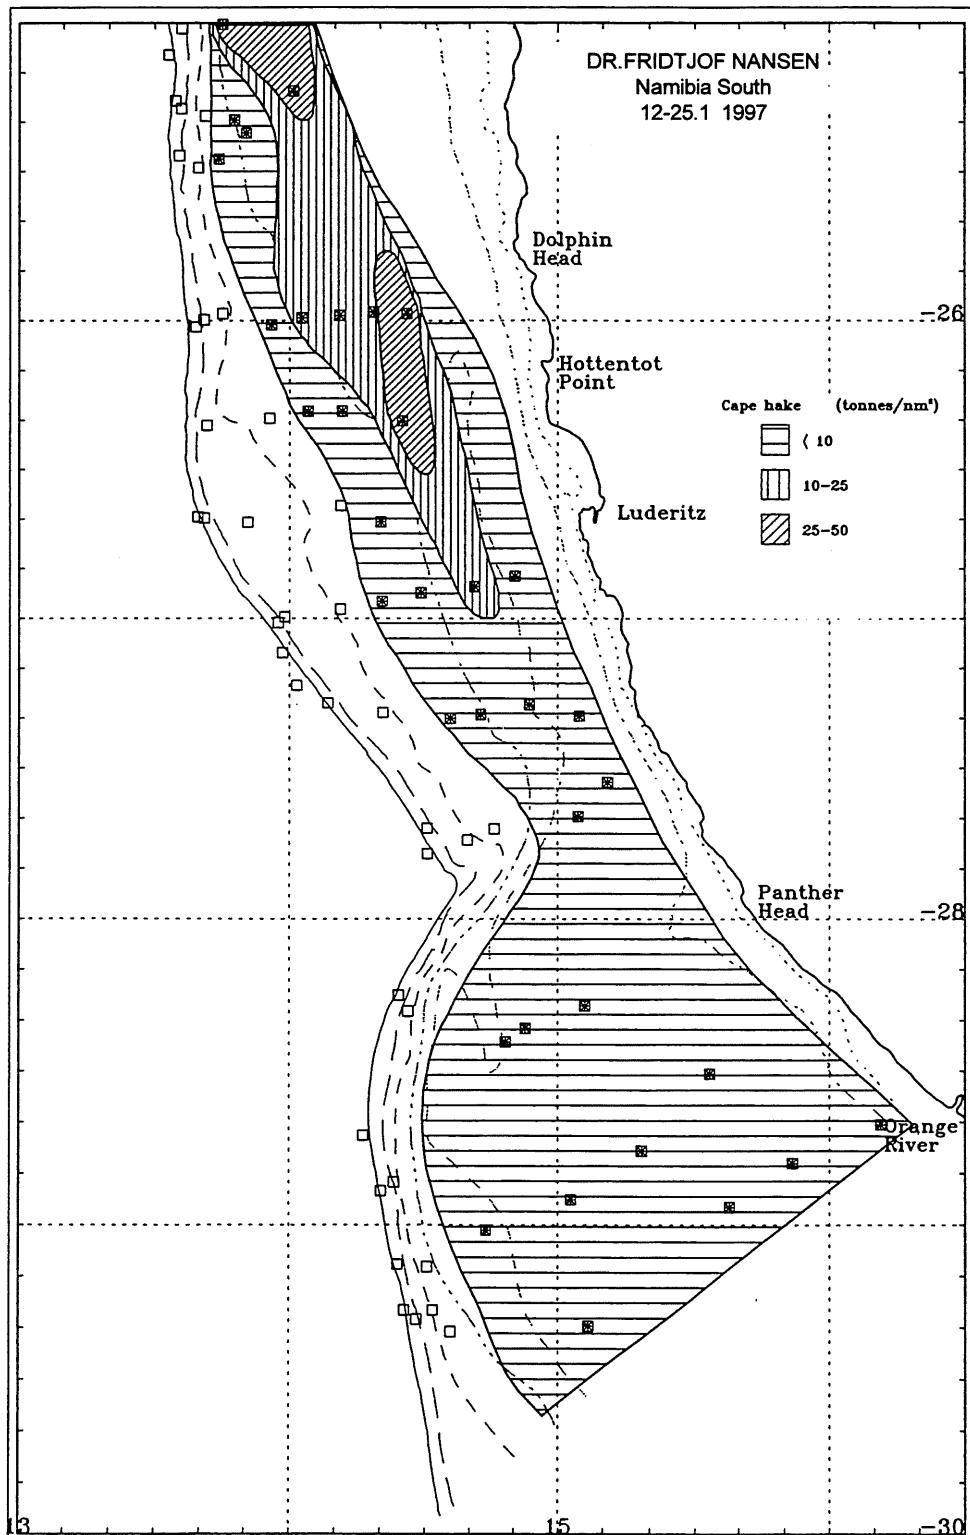

Figure 8 Orange River to Francis Bay. Distribution of Cape hake. Empty squares indicate stations where Cape hake was not caught.

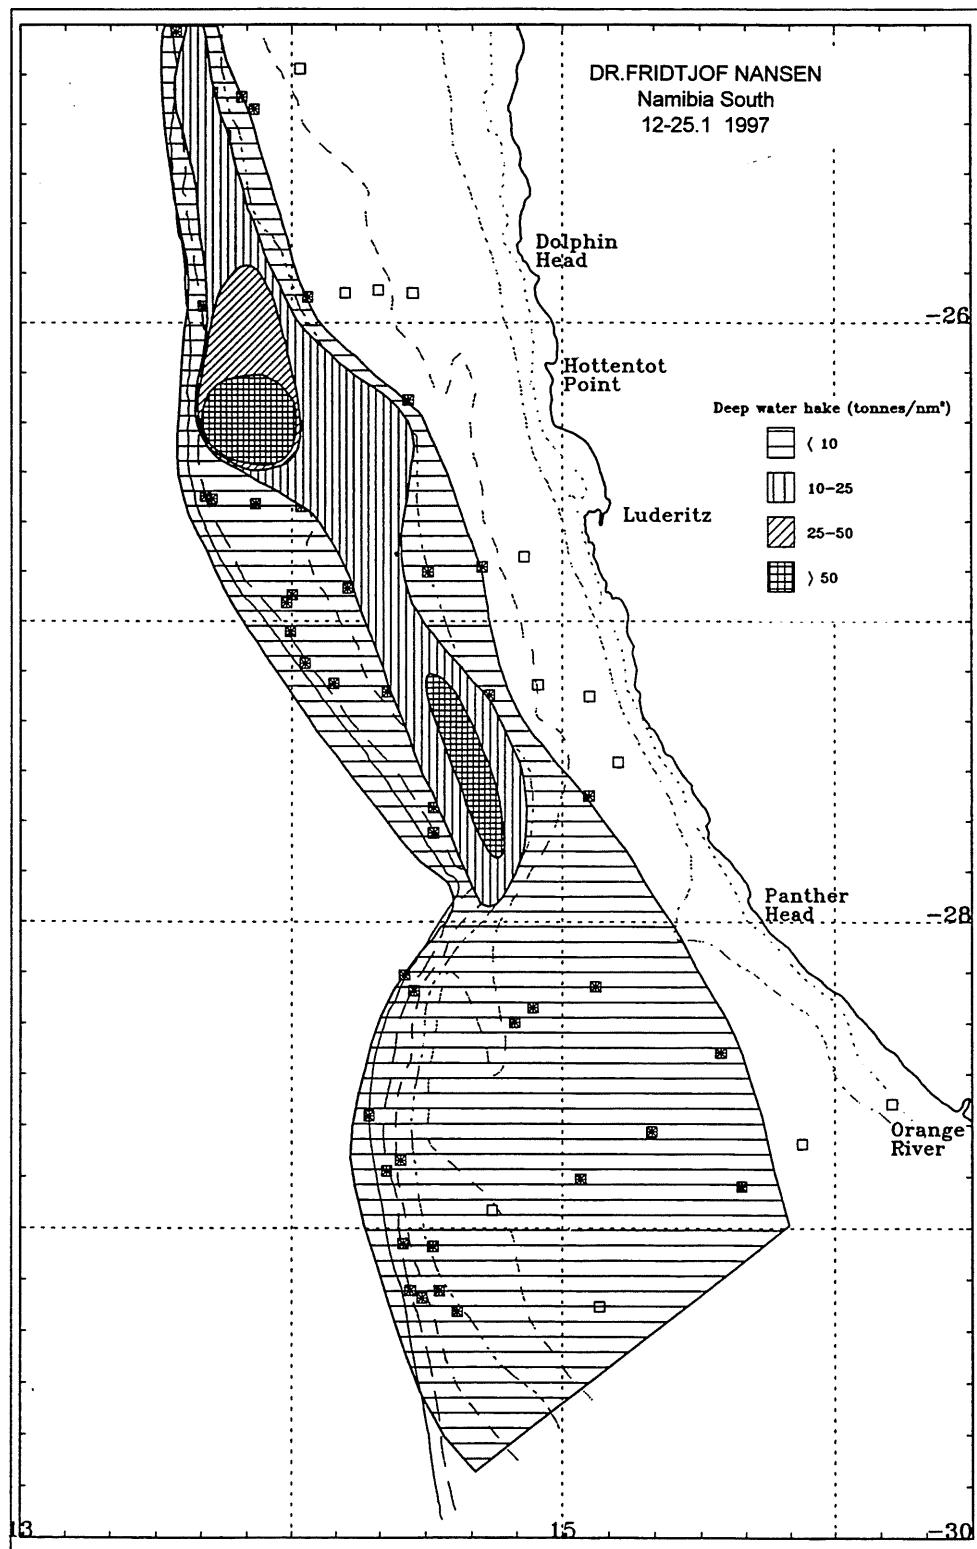

Figure 9 Orange River to St. Francis Bay. Distribution of deep water hake. Empty squares indicate stations where deep water hake was not caught.

The size compositions in biomass and numbers of the Cape hake from pooled samples weighted by catch rates are shown in Figure 10. A length frequency analysis to identify age groups (cohorts) in the stock, was performed in the same way as during the five previous surveys. The results are shown in Table 5.

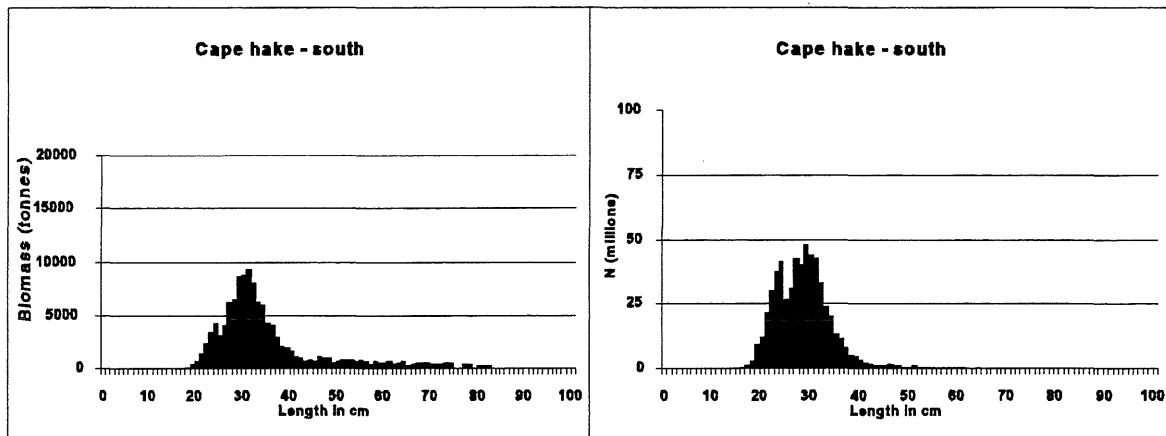

Figure 10 Length composition of Cape hake in biomass and numbers.

Table 5 Southern region. Cape hake. Estimated age-cohorts from optimized length distributions.

Year class	Mean length	Sigma	Fraction of all fish	Population million N	Biomass 1 000 t

1993	35.0	2.8	0.13	85	24
older			0.04	25	24

As seen in Figure 10 the main part of the Cape hake, both in numbers and biomass was made up of a fish cohort with mode at 29 cm, believed to be the 3-yearlings from the 1994 year class. Table 5 shows that this group constituted 50% of the population in numbers and biomass.

The fishable biomass was estimated to 37 000 tonnes and 64 million fish. This represents a recovery from the record low estimate of 14 000 tonnes in September 1996, but is still below the January 1996 figures (51 000 tonnes).

The size composition of the deep water hake is shown in Figure 11 and the results from the cohort slicing in Table 6. The population was composed of a wide size range, from 20 to 70 cm,

and large fish constituted a fairly big share of the biomass. The fishable biomass was estimated to 71 000 tonnes.

3.3 Central region, St. Francis Bay to Ambrose Bay

Table 7 shows the catch composition for the shelf and the slope by main groups. The mean catch rates for both hakes combined had decreased both on the shelf and on the slope since the last survey. The decrease was from 812 to 510 kg/hour on the shelf and from 372 to 304 kg/hour on the slope. The on-shelf catches were mainly consisting of young fish, so called 'non-fishable' biomass. For monks, the catch rates on the shelf were similar to the October survey and they dropped in the slope from 13 to 4 kg/hour.

Table 7 Central region. Catch rates by main groups in swept area bottom trawl hauls, kg/hour.

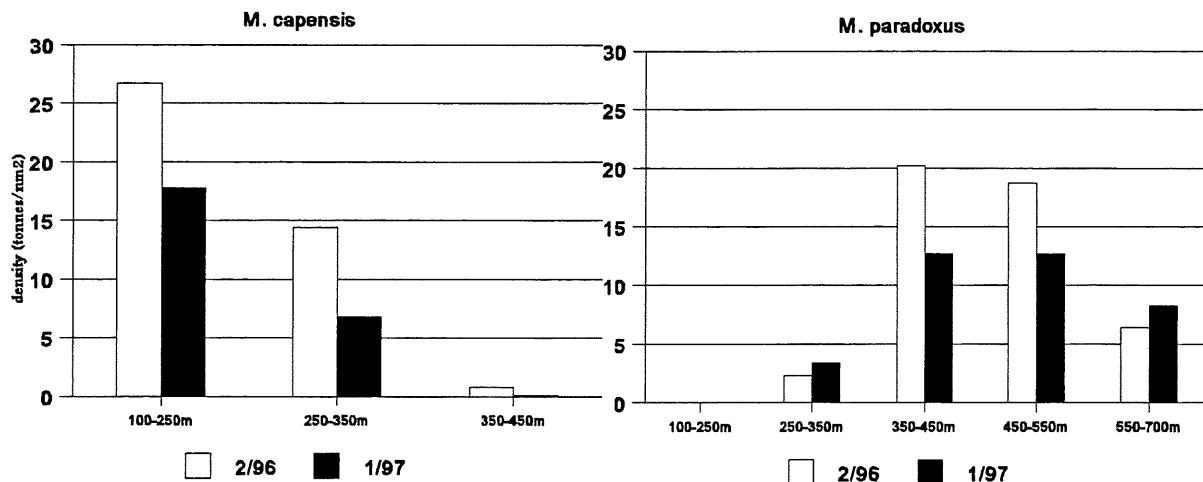

Figure 12 Central region. Depth distribution of two hake species. Mean densities in tonnes/NM².

Figure 12 shows the mean catch rates by depth ranges of the two hake species. The density for the Cape hake had dropped from 26 to 18 tonnes/NM² since the previous survey on the shelf. In the 250-350 m zone, the main habitat of adult Cape hake, the catch rates decreased from 14 to 7 tonnes/MN². The density for the deep water hake had decreased in its main depth zone, the 350-450 m from 20 to 13 tonnes/NM² and from 18 to 13 tonnes/NM² in the 450-550 m depth zone. A slight increase was observed in the 550-700 m depth zone.

Figure 13 shows the distribution of Cape hake over this region. Moderately higher aggregations (10-25 tonnes/NM²) were detected near Easter Point-Hollands Birds Island area, in the vicinity of Walvis Bay and in Cape Cross-Ambrose Bay area. Compared to the previous survey, these aggregations were smaller, the high density areas above 50 tonnes/NM² were lacking, and the densities were generally low in the region. A narrow band of moderately high aggregations for the deep water hake followed almost the whole slope in the region (Figure 14). This general observation is similar to the 2/96 survey.

95/1	105	40
96/1	145	73
96/2	182	58
97/1	112	46

The biomass estimate of Cape hake for the central region based on post stratification was 112 000 tonnes, a considerable drop from the

182 000 tonnes recorded four months earlier (Table 9). The biomass in the central region varies and some of the variation is associated with seasonal migration of adult fish with the summer months November-February as the low season in the 250-450 m depth habitat. The main part of the reduction is, however, associated with a decline in the young fish population on the shelf. The estimate of the deep water hake was 46 000 tonnes, about 20% decrease from October 1996 (Table 9). The 95% confidence limits on the estimates are $\pm 16\%$ on the Cape hake and $\pm 18\%$ on the deep water hake.

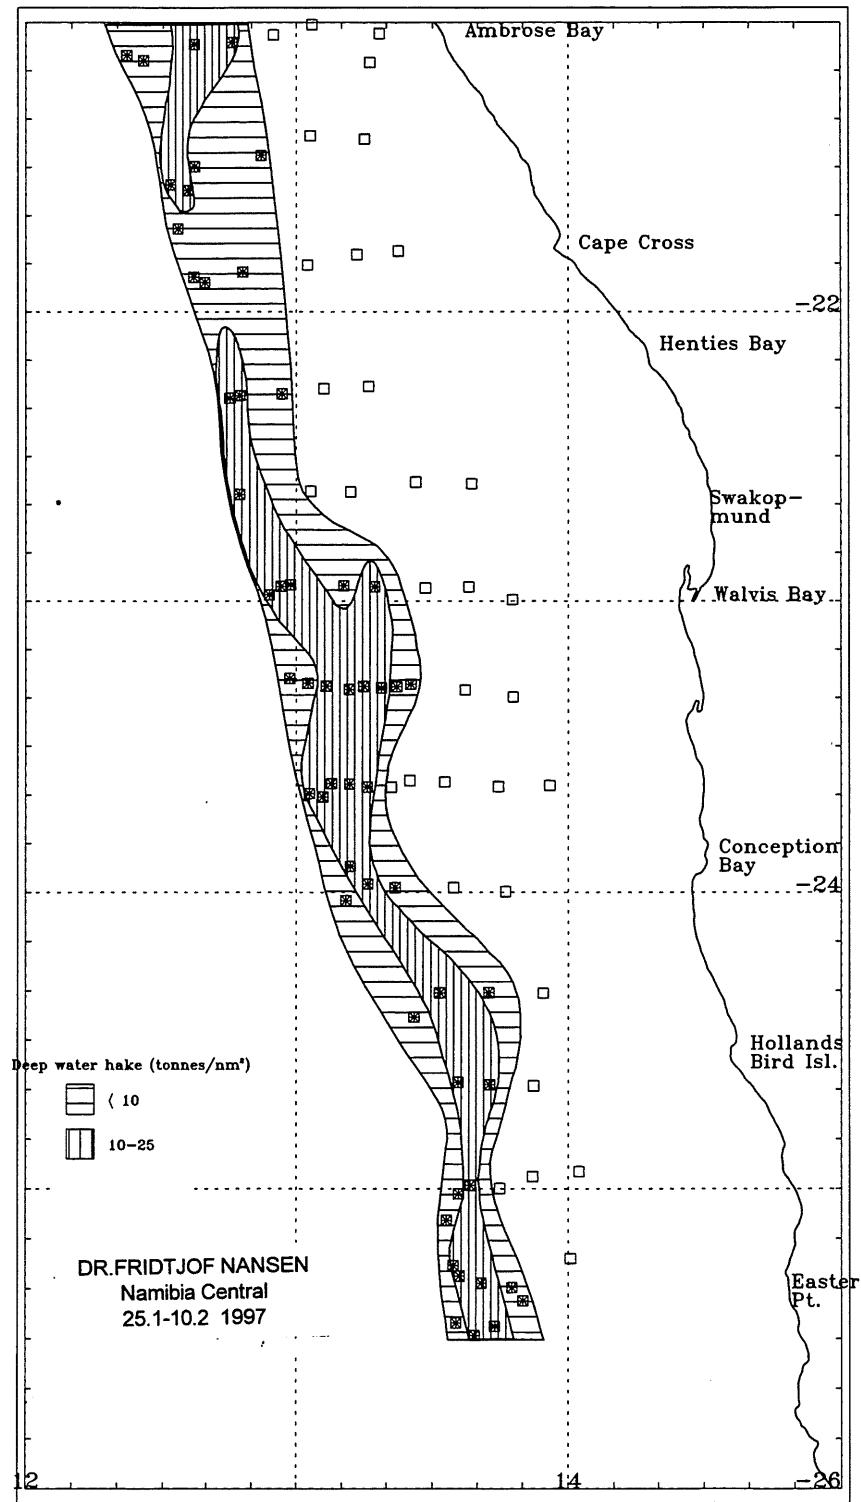

Figure 14 St. Francis Bay to Ambrose Bay. Distribution of deep water hake. Empty squares indicate stations where Cape hake was not caught.

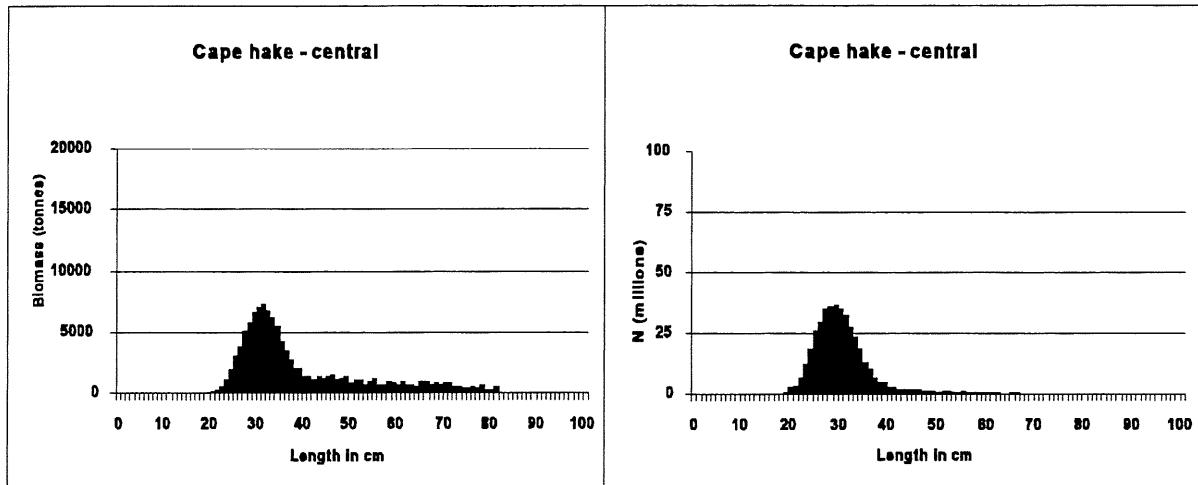

Figure 15 Central region. Length composition of Cape hake in biomass and numbers.

Size composition of Cape hake, in numbers and biomass, based on the pooled length samples is shown in Figure 15, and the results from the analysis are shown in Table 10.

Table 10 Central region. Cape hake. Estimated age-cohorts from optimized length distributions.

Year class	Mean length	Sigma	Fraction of all fish	Population million N	Biomass 1 000 t
1995	25.2	2.3	0.25	120	13
1994	29.7	2.8	0.53	258	45
1993	35.0	2.8	0.15	69	19
older			0.07	37	35

The 1994 year class, with a modal length around 30 cm, is about to enter the fishery and constitutes the dominating cohort in numbers and biomass. The fishable part of the Cape hake was 46 000 tonnes, a similar figure as was estimated in October 1996.

Size composition and the results from the cohort slicing on the deep water hake is shown in Figure 16 and Table 11 respectively. The regional population consisted mainly of fish from the 1993 and 1992 year classes, i.e. 4 and 5 year old fish. Fishable biomass was estimated to 40 000 tonnes.

older			0.03	3	4

3.4 Northern region, Ambrose Bay to Cunene River

Table 12 shows the catch rates by main groups for the shelf and slope separately. The mean catch rate for hakes showed a considerable increase in the shelf (from 169 - 310 kg/hour), but this was totally influenced by one big catch (5 060 kg/hour at station 2091), while in the slope the rates were similar to the previous survey (at about 330 kg/hour). The average catch rate for monk in the slope was down from 13 to 5 kg/hour compared to the previous survey, and on the shelf this species was not caught at all. Horse mackerel mean catch rate had dropped by half (from 1 528 to 707 kg/hour) on the shelf compared to the October 1996 survey, but the high figure in October 1996 was due to one extremely high catch (22 tonnes at station 1830).

Table 12 Northern Region. Catch rates by main groups in swept area bottom trawl hauls, kg/hour.

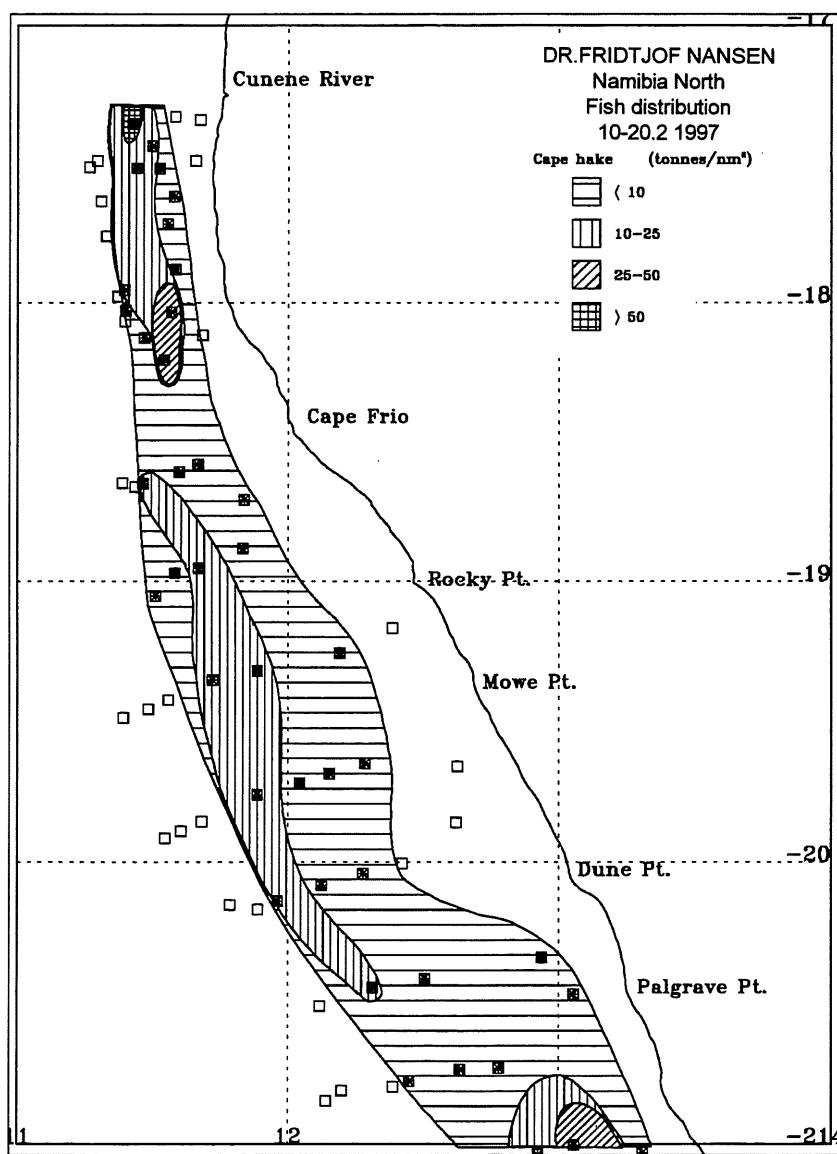

Figure 17 Ambrose Bay to Cunene River. Distribution of Cape hake. Empty squares indicate stations where Cape hake was not caught.

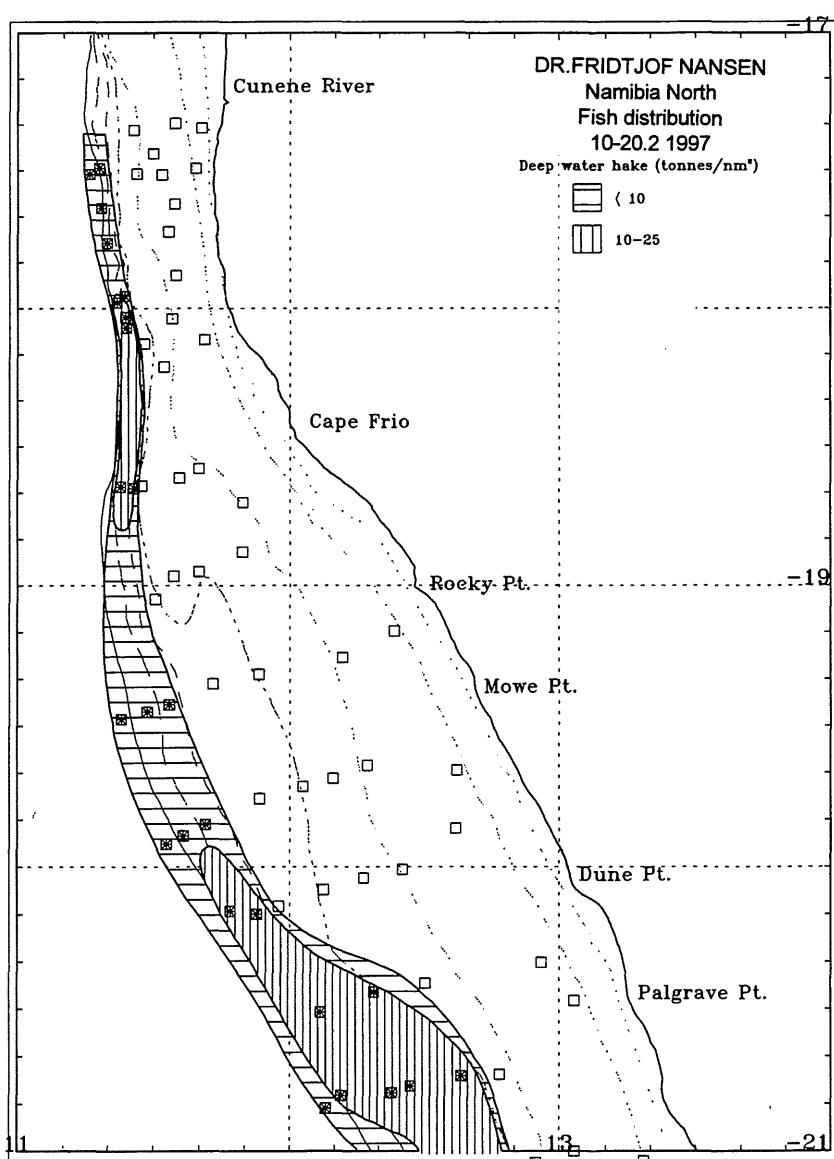

Figure 18 Ambrose Bay to Cunene River. Distribution of deep water hake. Empty squares indicate stations where deep water hake was not caught.

Figure 17 shows the distribution of Cape hake in the northern region by levels of density calculated from the catch rates and with correction for fish in mid-water. Generally the distribution pattern was much the same as during the previous survey, but a rather extensive area with moderate densities (10-25 tonnes/NM²) on the shelf between Cape Frio and Dune Point was now reduced. The deep water hake, Figure 18, had much the same distribution as during the previous survey, perhaps with some increased densities off Cape Frio.

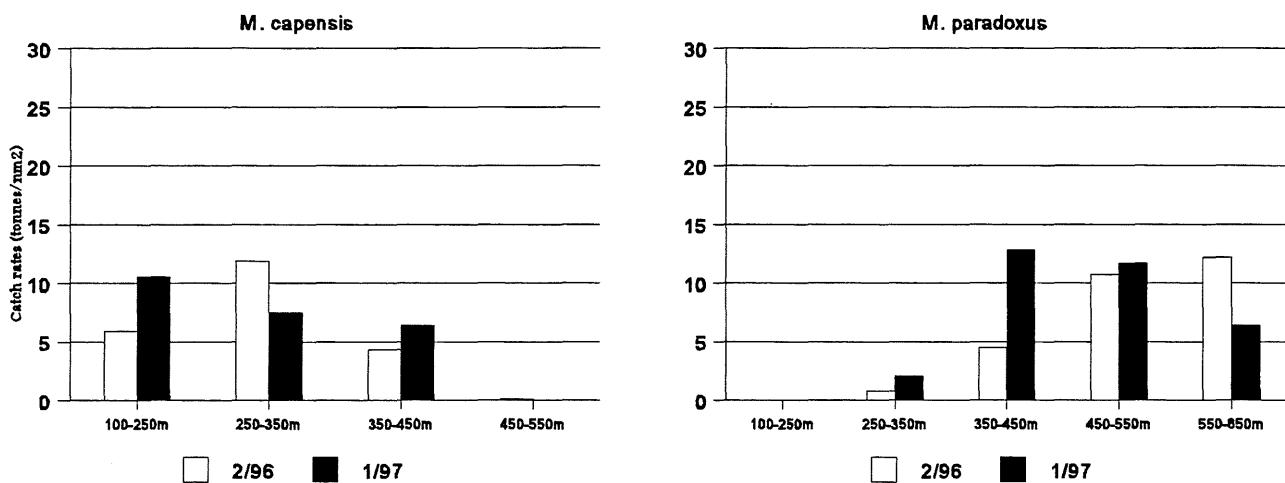

Figure 19 Northern region. Depth distribution of two hake species. Mean densities in tonnes/NM².

The depth distribution of the two hake species based on catch rates converted to densities is shown in Figure 19. Biomass estimates gave a total of 73 000 tonnes of Cape hake and 40 000 tonnes of deep water hake (Table 14). For the Cape hake this represents a decrease of 21 000 tonnes since the last survey. The deep water hake increased from 31 to 40 000 tonnes. The 95% confidence limits on the estimates of the Cape hake was $\pm 66\%$. This was due to very large catch at one single station. Without this station, the confidence limits would be $\pm 22\%$. For deep water hake the confidence limit was $\pm 22\%$.

Table 14 Northern region. Estimates of total biomass by surveys, 1 000 tonnes.

* + hake in the mid-water

The size compositions of the two hake species are shown in Annex I. A cohort analysis was done on the two hake species and the results are shown in Tables 15 and 16. The so called 'fishable biomass' of Cape hake in the northern region, representing fish of 36 cm and larger, constituted 95 000 tonnes. This is 20 000 tonnes more than the fishable biomass estimated from the previous survey. The non-fishable biomass was now about 19 000 tonnes.

Figure 20 shows the biomass distribution of Cape hake by length classes. Both Table 15 and Figure 20 show that the biomass was composed mainly of adult fish.

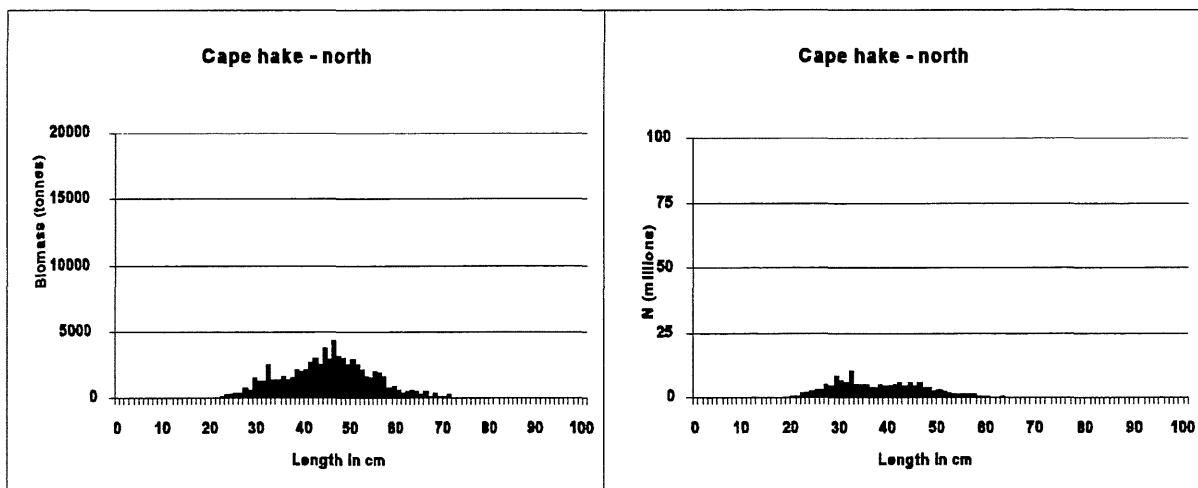

Figure 20 Northern region. Length composition of Cape hake in biomass and numbers.

Table 15 Northern region. Cape hake. Estimated age-cohorts.					
Year class	Mean length	Sigma	Fraction of all fish	Population million N	Biomass 1 000 t
1995	23.5	2.0	0.06	10	1
1994	30.2	3.0	0.35	61	11
1993	39.0	3.8	0.28	49	19
1992	46.0	3.0	0.21	36	23
older			0.10	17	19

The estimated fishable biomass of deep water hake was 37 000 tonnes. Figure 21 shows that the whole biomass of deep water hake was adult fish.

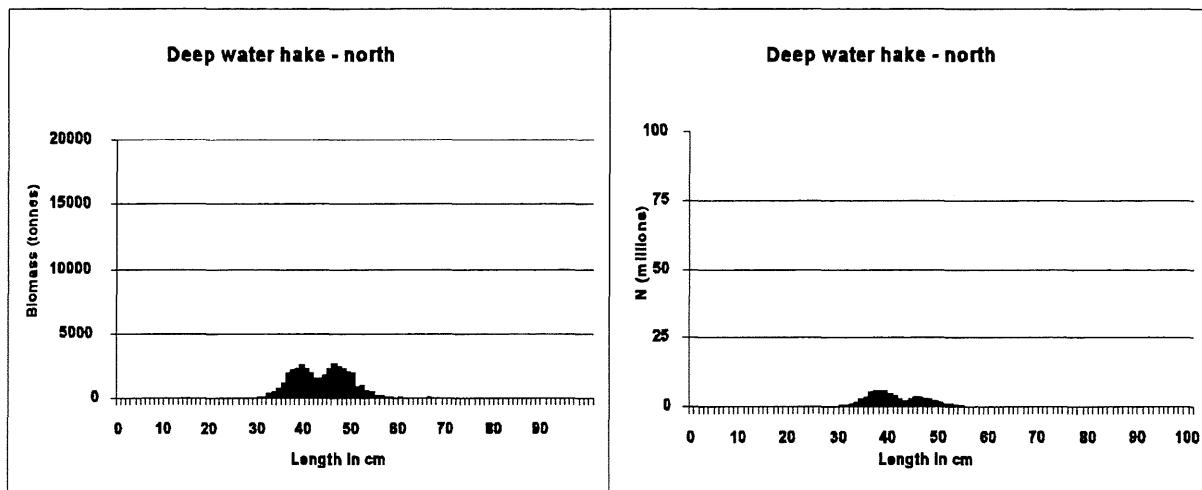

Figure 21 Northern region. Length composition of deep water hake in biomass and numbers.

CHAPTER 4 CONSIDERATIONS ON THE SURVEY RESULTS

4.1 Survey effort

The present survey was the 15th in a series started in early 1990, covering the distribution of the hake stocks over the whole Namibian shelf. Figure 22 shows the effort spent in these investigations. This survey was done in 42 days. Of this about one week was spent on intercalibration and special studies on trawl performance.

Hakes may be partly inaccessible to the trawl-net due to vertical migration. However, the use of acoustic assessment techniques and the Bergen Echo Integrator (BEI) post processing system enables the inclusion of the biomass in the overlying water column in the assessment. It is therefore not likely that major off-bottom aggregations of hakes have been missed. The occurrence of hakes in mid-water was more pronounced in the northern region. During the recent survey the average acoustic corrections during daytime were 1%, 4% and 18% for the south, central and northern regions respectively. The corresponding figures for the night hauls were 3%, 15% and 23%. For logistic reasons a limited number of night hauls were carried out.

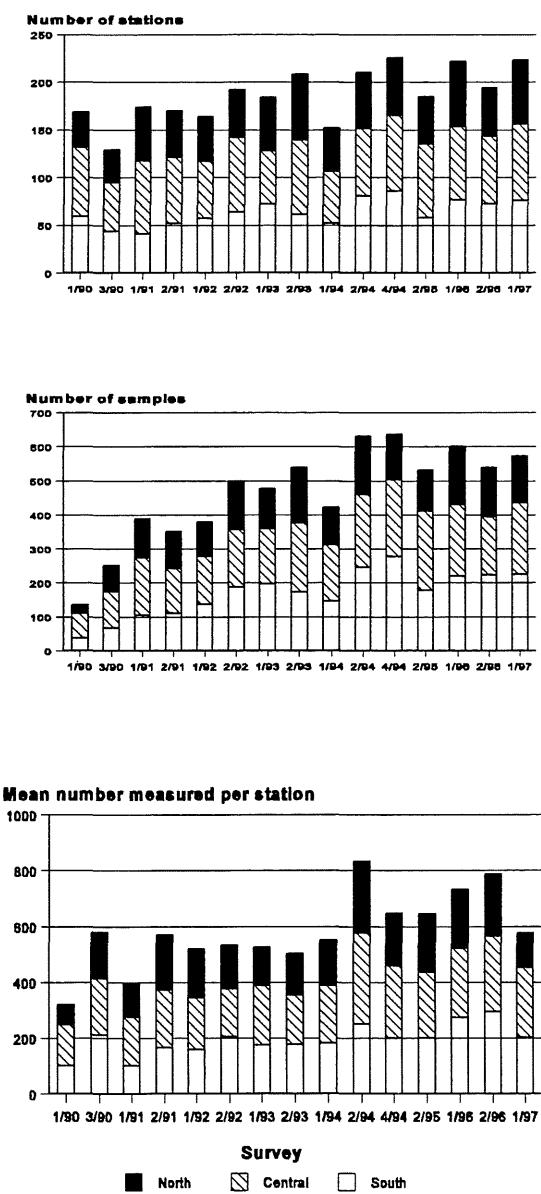

Figure 22 Hake survey effort 1990-97. a) Number of trawl stations by regions; b) Number of length frequency samples by regions; c) Mean number of fish in length sample.

These were usually fished carried out on the peripheries of the fish distributions where the densities are low and the corrections in absolute terms are small.

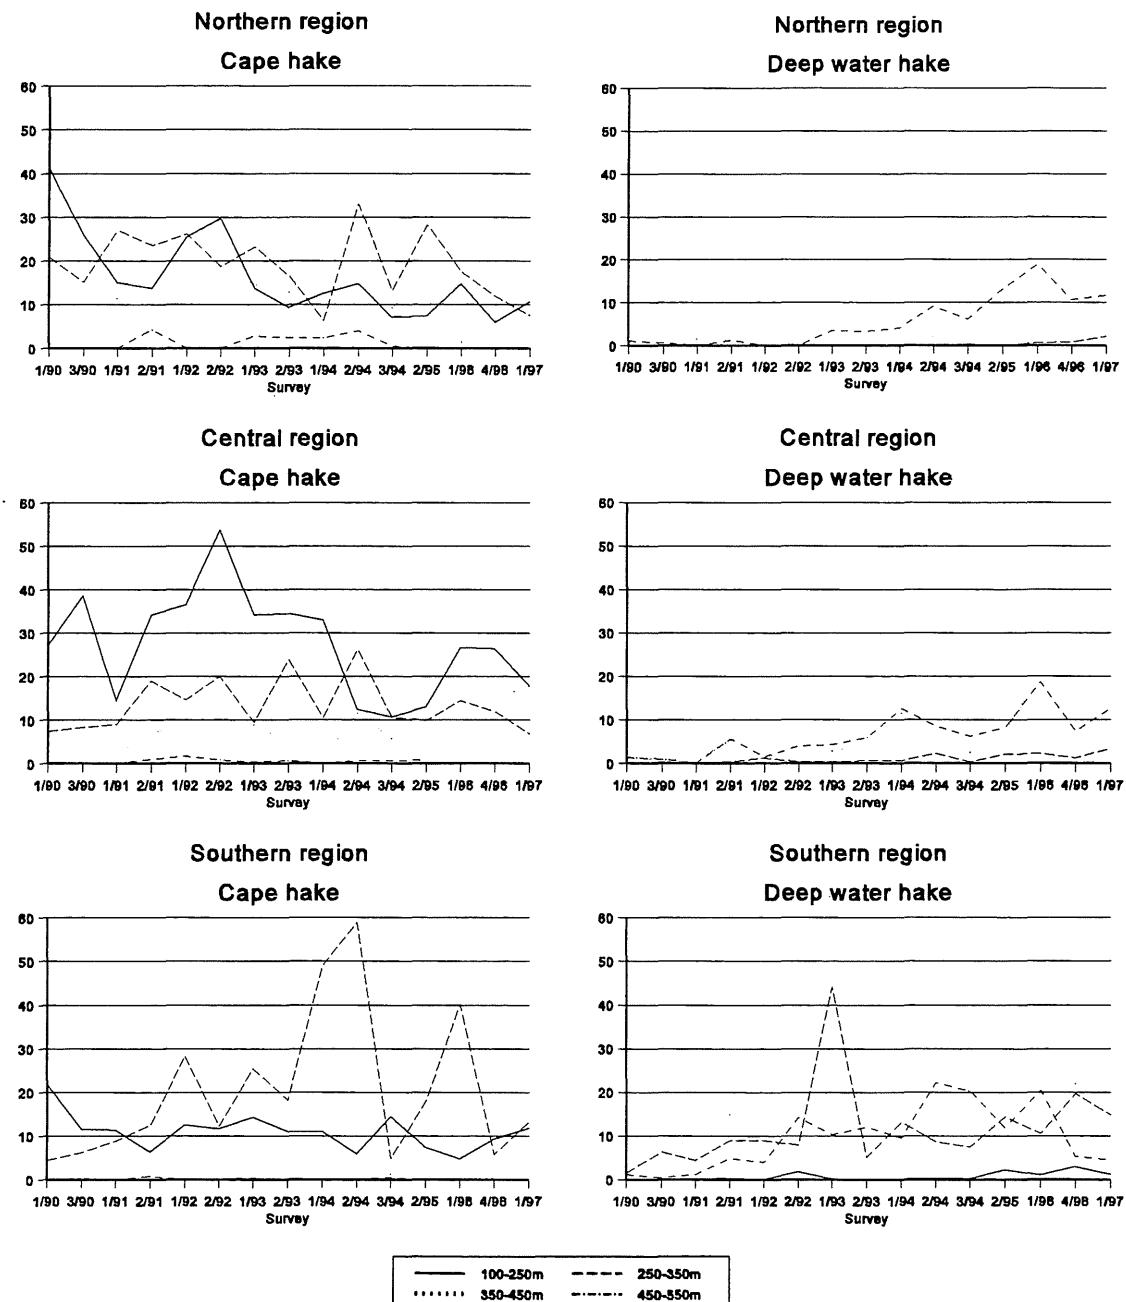

Figure 23 Estimated mean densities in depth strata by surveys. Mean densities in tonnes/NM². Biomass estimates.

4.2 Catch rates

A summary of the estimates of the mean densities (these are linearly correlated with catch rates) of the hakes by depth stratum is shown in Figure 23. The densities in the shallow ranges 100-250 m mainly reflect the strength of the young fish, 2-3 years of age, that inhabit this zone. The hauls in each zone were too few to give statistical valid conclusions, but the Cape hake figures from the last surveys confirm the low catch rates obtained in the two previous surveys. For the deep water hake the catch rates in all depths have been on a slow increasing trend and the figures from the last survey generally followed this trend.

Table 17 Summary of total, fishable and non-fishable biomass estimates for the two hake species by surveys and areas. 1 000 tonnes.

4.3 Biomass estimates

Table 17 and Figure 24 give the up-to-date summaries of the biomass estimates for the two hake stocks by region and survey since the beginning of the survey programme in 1990.

Figure 24a-d shows the summaries of estimated fishable, nonfishable and total biomass of hake species since 1990. The fishable biomass of Cape hakes grew from about 106 000 tonnes in 1990, reaching a peak of 400 000 tonnes in 1992 and was at 142 000 tonnes in the present survey (Figure 24a). The last survey represents a moderate recovery from the record low level of biomass obtained from the previous survey but still confirms a general low level of fishable Cape hake. The sign of recovery is the relatively strong 1993 year class which during 1996 has fully recruited into the adult biomass. This recruitment has, however, not been enough to compensate for the fishing during the same period as the net production in the adult stock is negative from the beginning of 1996 to the beginning of 1997, - 40 000 tonnes. The estimated

fishable biomass of deep water hakes increased tenfold from 20 000 tonnes in 1990 to about 200 000 tonnes in early 1994 (Figure 24b), has varied since then and was estimated at 146 000 tonnes in this survey. The present fishable biomass of deepwater hakes is close to what was observed in the previous survey. An interesting point is that the adult population of deepwater hake is equal to the Cape hake in abundance (142 000 for Cape hake and 146 000 tonnes for deep water hake). The apparent reduction of deepwater hake since early 1996 could be interpreted positively as a sign that fishing during 1996 has been directed to a greater extent towards the deeper waters, the habitat of this species. In previous reports the deep water hake has been pointed to as a underutilized fish resource in Namibia due to the traditional preference of the fleet to work in shallower waters. It would be interesting to check this hypothesis against the catch composition during 1996 as collected by the observer programme.

The non-fishable biomass, Figure 24c, is about 240 000 tonnes of which 165 000 tonnes is Cape hake (Table 17). This is, relatively speaking, a very low level of young Cape hake, consisting mainly of two year classes, the 1994 and the 1995 year class. A moderate abundance of recruits from the 1994 year class has been observed during the two surveys of 1996 and is now in the 27 to 35 cm length range and has already partially recruited to the fisheri. Through the rough method of cohort slicing in the reports this cohort was estimated to 1 700 mill. fish in February 1996, 1 350 mill. in October 1996 and 650 mill. in February 1997. The corresponding biomass figures were 158, 135 and 101 000 tonnes respectively. The fast number reduction of this cohort suggests that it is a main target for the fisheries during 1996 and that it is subject to strong growth overfishing. The 700 mill. fish of this cohort that have disappeared since October would make up 70 000 tonnes in October but would represent about 110 000 tonnes by February if all had survived until then. A comparison with catch data from the fisheries during 1996 would be very useful and could perhaps also be used to tune the trawl biomass index. These catch data are not yet available.

In February 1996, the 3-year cohort, then recruiting to the fishable biomass was estimated to 128 000 tonnes. In February 1997 the same cohort was estimated to 114 000 tonnes, which is about the same strength as the previous year. If the fishing pressure on the Cape hake is kept constant during 1997 a further reduction of the adult stock is expected.

According to the estimated total hake biomass, the hake resources grew steadily from 522 000 tonnes to a million tonnes between 1990 and late 1992 (Figure 24d). Since early 1993, the resources have been on a declining trend, reduced to a level of about one halfmillion tonnes by October 1994. A slight upward trend was observed in mid 1995 and to early 1996 due to the

incoming 1993 and 1994 year classes. However, the results of the last two surveys fall back into the negative trend of the biomass estimates of the later years and give serious reasons for concern. The total estimate of both hake stocks during the present survey is 525 000 tonnes, which is at the same level as the 1990 estimate of total hake biomass. But in the same period about 200 000 tonnes of Cape hake has been replaced by deep water hake, a stock that is probably shared with South Africa and has its center of distribution and reproductive areas outside Namibia.

4.4 Size composition

Figure 24 shows the estimated size distribution in numbers and biomass for the Cape hake for all three regions combined. The figure shows that the stock was dominated by the three-yearlings with a modal length around 30 cm. For fish above 40 cm the abundance was very low in the southern and central region, most of this fish being concentrated in the relatively small areas in the northern region. One should note the near absence of fish in the 20-25 cm range. This is a very unusual feature for a January-February survey and is further discussed below.

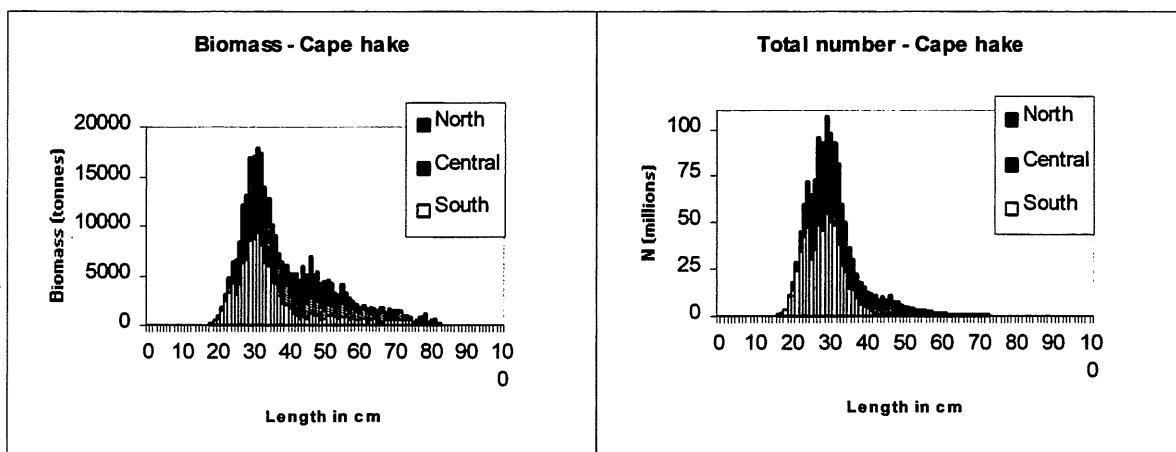

Figure 24 Length composition of Cape hake in biomass and numbers

The size distribution of the deep water hake is shown in Figure 25. In the very south a small area is functioning as a nursery area for young fish, 20-25cm. The low abundance of young fish indicates that most of the recruitment is through immigration from South Africa. The three-yearlings were almost exclusively concentrated in the south, the four-yearlings had about 50% of the biomass in the south while the older fish were more evenly distributed between the three regions. This distribution pattern could be explained by a gradual dispersal of the stock northwards as it grows.

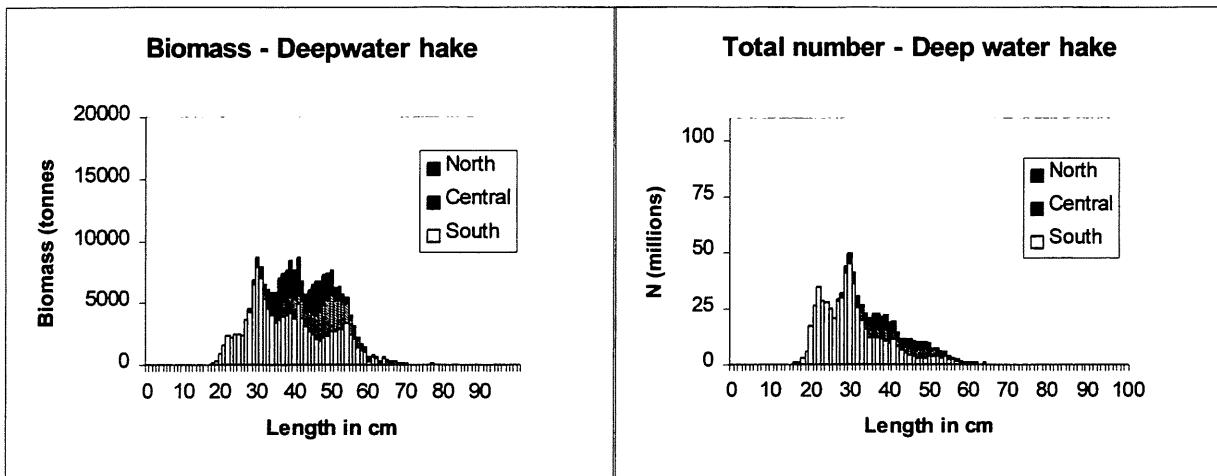

Figure 25 Length composition of deep water hake in biomass and numbers.

4.5 Geographic shift in the fishable biomass

Figure 26 shows the development of the relative share of the fishable biomass of Cape hake in the regions for the last six years. The northern region has been rather stable over the last three years, accounting for about 40% of the adult Cape hake population. A recent increase in the share of fish in the southern region is associated with recruitment of the 1994 year class to the fishable biomass in the south at the same time as the 1993 year class has been reduced by fishing, especially in the central region.

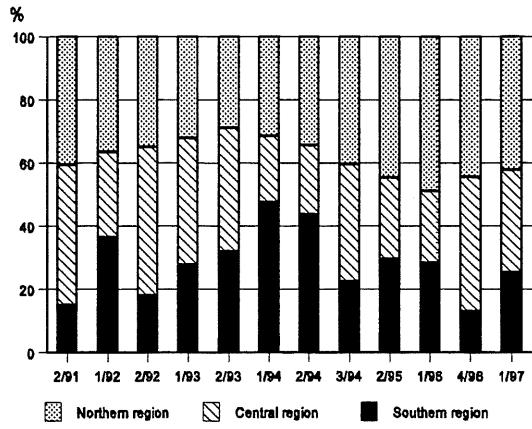

Figure 26 Relative regional share of fishable biomass of Cape hake 1991-97.

4.6 Recruitment potential

Incoming recruits to the stock of Cape hake can be estimated from the numerical abundance of the 1.5-2 year old fish. The young fish settle at the bottom usually in early spring (October-November) which is the first time one may assess and estimate the strength of year classes by trawl surveys. Table 18 shows the recent estimates for the 1995 year class, together with previous observations of the two-yearlings. A 'normal' recruitment level after two years is usually around two billion fish ± 200 million. The 1995 year class estimated from this survey consisted of about 330 mill. fish, an alarmingly low level which has not been recorded before.

This points indicates a serious reproductive failure for the 1995 year class, which will effect the recruitment to the fishable stock during 1998. For two years ahead there are therefore no signs of improvement in the adult stock of Cape hake and for 1998 a further decline in the adult stock is possible if the present level of harvest persists.

Table 18 Estimates of strength of recent year classes of Cape hake. Cohort population numbers at about two years of age for the groups assumed to have been spawned in 1988, 1989, 1990, 1991 and 1992. Millions of fish.													
Year class	1988	1989	1990	1991	1991	1991	1992	1992	1993	1993	1994	1994	1995
Southern region	980	100	300	990	670	390	250	2 308	1 730	510	485	672	10
Central region	1 320	170	1 620	3 500	1 230	1 370	1 880	3 017	490	430	1 030	1 313	120
Northern region	10	10	240	440	270	130	70	5	190	80	0	342	200
Total	2 205	515	1 518	4 930	2 170	1 890	2 200	1 235	2 410	1 020	1 515	2 327	330
Survey/Year	1/90	1/91	1/92	2/92	1/93	2/93	1/94	2/94	3/94	1/95	1/96	4/96	1/97

In Table 19 the non-fishable biomass is split by the age classes identified through the cohort analysis. The table shows that a large proportion of the recruits (167 000 tonnes) belongs to the cohort that is now three years, the 1994 year class. These fish have now a mean around 30 cm and are about to recruit to the fishery. As already mentioned the the 2-yearlings of Cape hake are very low in abundance and this is confirmed by the 29 000 tonnes in the table. For comparison, the 1994 year class, now at 114 000 tonnes, was estimated to 130 000 tonnes when it was in its second year, in February 1996.

Table 19 Recruit biomass by species and age groups. 1 000 tonnes.			
	1 year	2 year	3 year
Cape hake	-	29	114
Deepwater hake	-	12	53
Total	-	41	167

4.7 Management considerations

The main management policy for hake resources in Namibia is by limiting fishing mortality through the limitation of TAC. This policy recommends a yield of about 20% of the fishable biomass to reserve part of the biomass production to rebuild the resources. This level of fishing mortality is based on the general experience with fish with similar life span and growth rate. The

policy has not been entirely successful, particularly in recent years when the reported catches by far exceeded 20% of the fishable stocks biomass, Figure 27.

Further, as demonstrated, the recruitment level has been low during the last six years. The combined effects of low recruitment and high exploitation rates result in probably a strong reduction of the parent stock of Cape hake. During the last three years, annual catches were about or greater than 30% of the total fishable stock, Figure 27. High numbers of 1994 recruits have started entering the fishable biomass. The sizes of a landed hake from some commercial vessels show alarmingly high proportions of small sized hakes throughout 1996, and this indicates serious growth overfishing in the stock of Cape hake. This implies that the 200 m depth limit is not sufficient as a management option for hake as the fish still is fished before it has taken out its growth potential.

The fishable biomass is at present about 50% each of Cape hake and deepwater hake. But there are still reasons to assume that the main part of the fishing is on the more shallow Cape hake which is more accessible to the fishing fleet.

There are signs that the fishing fleet partly has moved to the deep water hake locations, but we have yet no statistical figures to support this.

The main part of the Cape hake of sizes larger than 40 cm is in the last survey located in the northern region (Figure 24), in a fairly limited area where catch rates are expected still to be high. These limited hot spots of the remaining established parent stock are already fished upon and could be diminished alarmingly during 1997. It should be considered if the area north of Cape Frio should be declared a protected area as a safeguard against stock collapse of Cape hake. It is also advisable that the fishery is moved more towards the deep water hake which is in a healthy state in Namibia and is present in all three regions Figure 25.

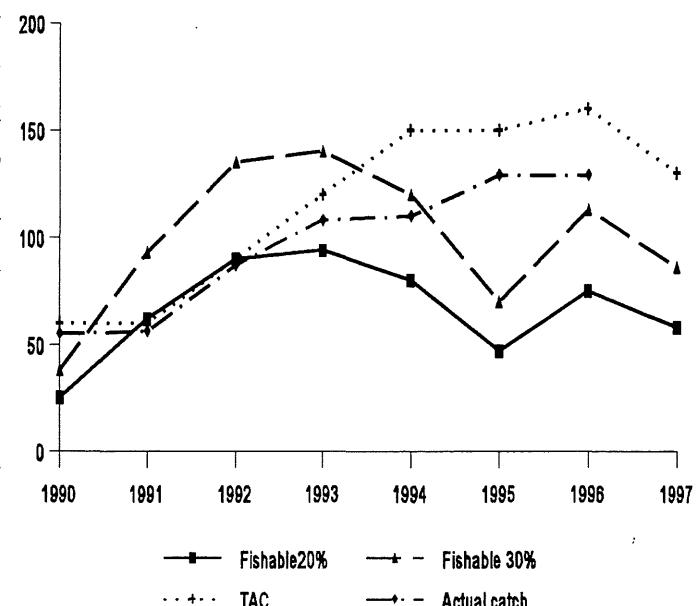

Figure 27 Management TAC, TACs as 20 and 30% fraction of fishable biomass and total catch 1990-97.

The general conclusion is that the present harvest level of Cape hake is far beyond the present production in the stock. The harvest pattern does not utilize the growth potential of the individual fish and also puts the reproductive capacity of the stock in jeopardy. The stock of Cape hake is therefore at present subject to both growth and recruitment overfishing.

Strong measures should be taken to reduce the catch. The deep water hake is in a much more healthy condition and would withstand a considerably higher fishing pressure. Management measures that direct the fisheries towards the deep water hake should therefore be implemented.

CHAPTER 5 COMPARATIVE FISHING EXPERIMENT WITH R/V AFRICANA (by Ingvar Huse)

5.1 Introduction

As it is assumed that a partial migration of hake takes place between South African and Namibian waters and there consequently might be a future wish to co-ordinate stock assessment and management, it was agreed to carry out intercalibration exercises in order to facilitate the comparison of data on hake stock abundance from both areas. Such intercalibrations are recommended in the BENEFIT science plan.

5.2 Materials and methods

DR. FRIDTJOF NANSEN arrived at the rendezvousposition south of Orange River at 05:30 h on 13 January. After a planning meeting on board AFRICANA the intercalibration started with parallel hauls 2 cables or more apart. Both vessels were maintaining normal trawling procedures respectively, according to Table 20.

Table 20. Tow parameters during the intercalibration						
	Tow time	Speed	Door spread	Wingspread	Vertical opening	Strapping*
AFRICANA	20 min.	3.5 knots	~100 m	~27 m	~2 m	No
DR. F. NANSEN	20 min.	3.0 knots	~ 54 m	~ 21 m	~4.6 m	Yes

*Strapping is restriction of door spread through the application of a 10 m long rope of which one end is attached to a mark on the port warp through a snap lock (on 'Nansen' at 130 m in front of the door), and the other end is running free on the other warp with a purse seine ring with a roller which can be opened to be hooked on to the warp.

AFRICANA was using heavy warps with diameter 32 mm, while DR. FRIDTJOF NANSEN was using lighter 24 mm warps. DR. FRIDTJOF NANSEN generally shot more warp than AFRICANA. The AFRICANA trawl was rigged without a groundgear, with only a heavy groundrope ('sabb'), 57 m long, while DR. FRIDTJOF NANSEN used a 47 m gear with low profile cylinders and rather few discs. AFRICANA did not use lower wing panels. The sweeps used were 50 m, while the DR. FRIDTJOF NANSEN sweeps were 40 m. The AFRICANA

trawl had mesh sizes ranging from 110 mm in the extension peace to 180 mm in the front panels and wings, while the DR. FRIDTJOF NANSEN trawl ranged from 22 to 40 mm. AFRICANA used 25 mm cod end mesh size while DR. FRIDTJOF NANSEN used 22 mm. Scanmar sensors were used on both ships to monitor door spread and vertical opening.

The intercalibration took place in South African waters on the shelf SW of Orange River and lasted for three days. The DR. FRIDTJOF NANSEN followed in the normal survey activity of the AFRICANA and carried out parallel hauls at each trawl station. Trawls were only shot during daylight hours, generally between 07:00 h and 19:00 h. Personnel for intercalibration of fish classification and measurement were not exchanged this year. Altogether, 17 parallel hauls were made at depths between 92 and 473 m. One haul was discarded due to a problem on the DR. FRIDTJOF NANSEN, giving a total of 16 usable pairs of hauls, one haul less than in last year's intercalibration.

All catch figures were corrected for swept area. AFRICANA's swept area was calculated with the following formula:

$$A_A = V * 1852 * T / 60 * S_A$$

where A_A is swept area in m^2 , V is ship speed, T is tow time (bottom time) in minutes and S_A is wing spread in meters. The ship speed was set at 3.5 kn. for all hauls. A wing spread of 27.86 m was used for all hauls, as this was the average wing spread for AFRICANA in the 1995 intercalibration.

DR. FRIDTJOF NANSEN's swept area was calculated with the following formula:

$$A_N = D * 1852 * S_N$$

where A_N is swept area in m^2 , D is towed distance measured from GPS plotter track, and S_N is wing spread. A wing spread of 21 m was used for all hauls, also according to the 1995 intercalibrations. Swept area corrections were made according to following formula:

$$N_A = N * 1000 / A$$

where N_A is the number of fish per 1000 m², N is the number of fish in question, and A is swept area either of AFRICANA or DR. FRIDTJOF NANSEN. Fish weights were corrected in the same manner.

A two tailed Student's t-test for paired samples was used for all comparisons of catch numbers, catch weights and length groups.

5.3 Results and discussion

Experimental set-up and execution

The organisation and execution of the intercalibration went without problems of any kind. As the results will show, however, we probably would wish to have more hauls to sufficiently demonstrate potentially true differences which in the present experiments were only indicated. It is not likely that both ships will find room for more than three days of intercalibration at the same time, but the available time could be utilised better. It should be possible to carry out 7 or 8 hauls per day, giving a total of 21-24 hauls. This would, however, necessitate both ships to have the intercalibration as the sole purpose of these three days.

Swept area

Normally in considering swept area of trawl gear, e.g. in cod assessment, bridle length and door spread are very important parameters. As hakes were the target species of this investigation, the herding of these species has to be considered in particular. From experiments carried out on the DR. FRIDTJOF NANSEN in 1995 it seems that the herding efficiency of doors/bridles is far less pronounced for hake than for e.g. cod. Although the 1995 results from the herding experiments were to some degree internally conflicting, the overall impression was that herding of hake by bridles, doors and sand clouds is of little importance. In the hake assessment carried out by the DR. FRIDTJOF NANSEN, a sweeping width of 18.5 m is applied. This is even less than the observed wing spread, based on the assumption that there may be some avoidance over and under the trawl, and hardly any herding by bridles, sand cloud or doors.

In conclusion we have for this intercalibration chosen to adapt a swept width equal to wing spread as herding effect of bridles, doors and sand cloud may be of little importance for hake. In view of the implications of this aspect for trawl based assessment, herding efficiency should,

however, be further elucidated through comprehensive trials at varying water depths and times of day, preferably with two ships using the same trawl nets and varying other parameters like e.g. sweep lengths and bottom contact. In addition, constant monitoring of wing spread or calculated wing spread from door spread could be used to calculate average wing spread, and consequently, correct swept area, for each haul. These data are directly available from the SCANMAR system.

It should be noted that in the comparisons below the computations of the swept area are very decisive for the results, as it is always figures corrected for swept area which are compared. The swept area calculations for 1997 are, however, the same as for 1996, but the computations and comparisons are sensitive for year to year variation. There are e.g. indications that AFRICANA towed slower in 1997 than in 1996, and as the swept area is calculated on the basis of 3.5 knots rather than on the true speed this can easily lead to differences. Such differences are indicated below, and the too large swept area originating from applying a too high towing speed in the computations may well be the reason for this.

Hake

Results for hake are given in Figure 28 and in Annex V, Table 1, 2 and 3.

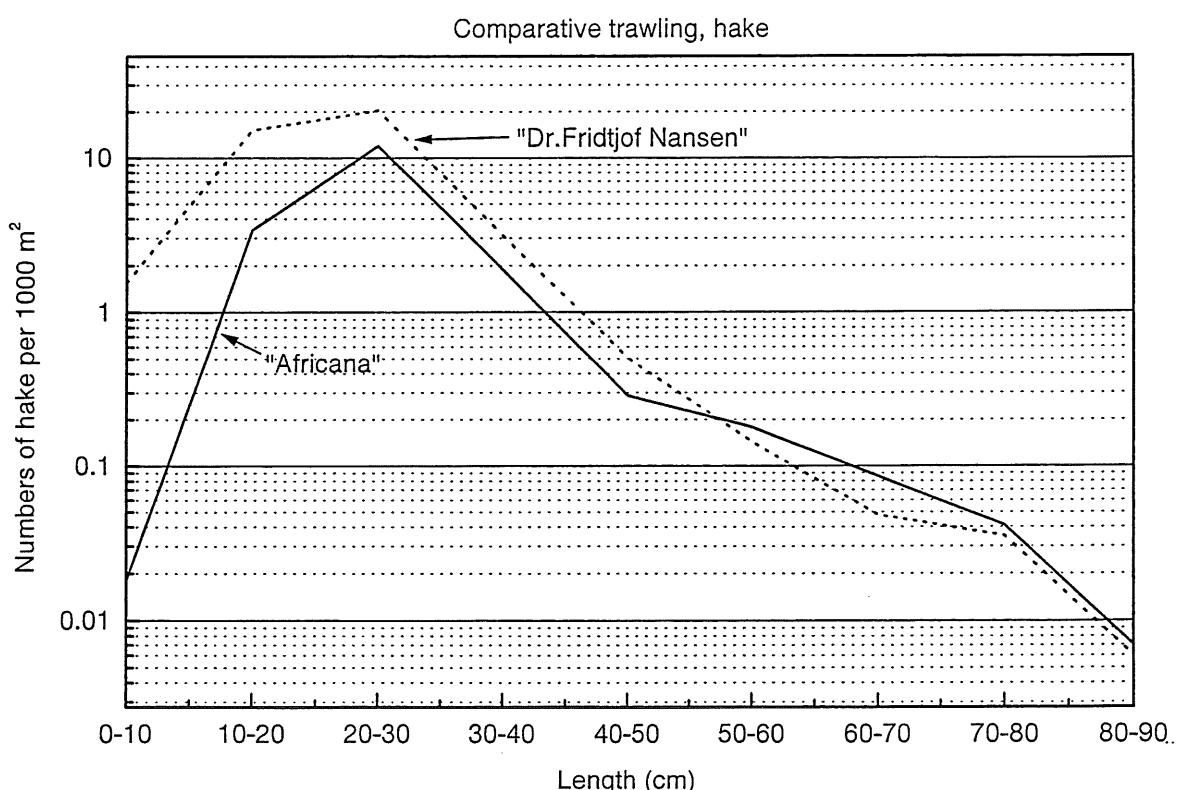

Figure 28 Numbers of hake in each length group for both ships. Logarithmic Y-axis.

DR. FRIDTJOF NANSEN catches were significantly higher than AFRICANA catches for 0-10 cm and 10-20 cm hake (Annex V, Table 2). For the 0-10 cm group this was probably due to mesh selection related to the difference in cod-end mesh size. For the 10-20 cm group the difference is more likely to be related to mesh selection further ahead in the trawl, or to escapement over the low opening AFRICANA trawl. For other length groups there were no significant differences in catches. Generally the picture was the same as in the 1996 intercalibration.

For the hake, DR. FRIDTJOF NANSEN obtained significantly higher mean rates per unit swept area, in numbers than AFRICANA (Annex V, Table 2), but in weight the difference was not significant ($p=0.06$) (Annex V, Table 1). Also in 1996 the DR. FRIDTJOF NANSEN also obtained the highest mean catch rates in numbers and weight, but then none of the differences were significant.

Other species

Catches of monk, gurnard and kingklip are considered good indicators of bottom contact of the two trawls. AFRICANA had higher, but not significantly higher catches of numbers and weights of gurnards (Annex V, Table 4) than DR. FRIDTJOF NANSEN. Monk and kingklip (Annex V, Table 4 and 5) catches were similar. These results are somewhat different from 1996, when AFRICANA had significantly higher catches of bottom contact indicator species than DR. FRIDTJOF NANSEN. The reasons for this is uncertain, but DR. FRIDTJOF NANSEN this year took care to avoid loss of bottom contact by using moderate speed and a high (3.3) warp length/depth ratio.

There were no significant differences in catches of horse mackerel Annex V, Table 5). DR. FRIDTJOF NANSEN caught somewhat less horse mackerel than AFRICANA which is the opposite of the 1996 results. This probably just shows that the patchiness of the horse mackerel distribution is more decisive for the results than differences in catch efficiency for the two trawls.

Total biomass

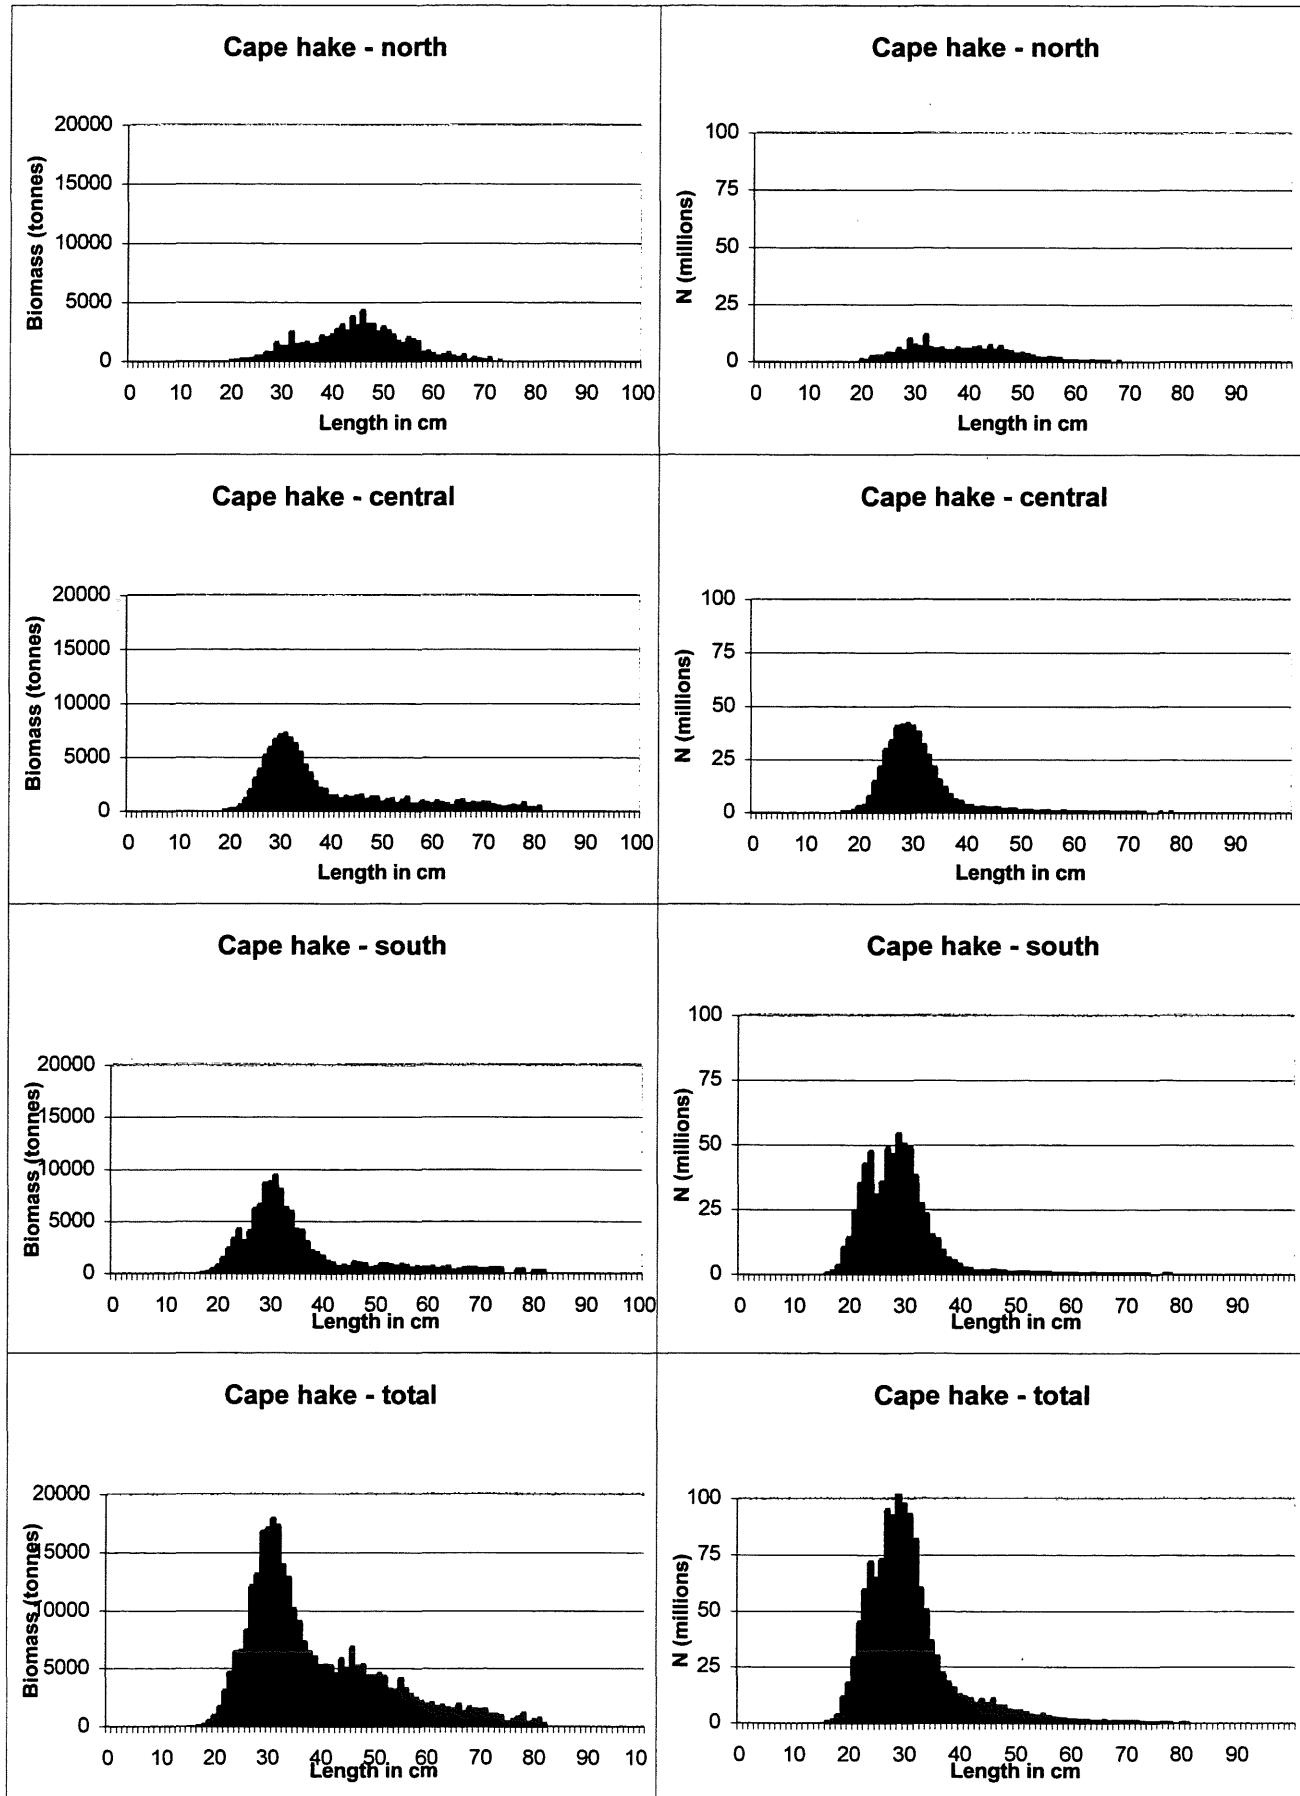

In 1996 AFRICANA had significantly higher average total biomass per haul per unit of swept area than DR. FRIDTJOF NANSEN. This was then assumed to be due to higher catches of large sharks and skates, probably caused by the wider door spread of the AFRICANA. In 1997

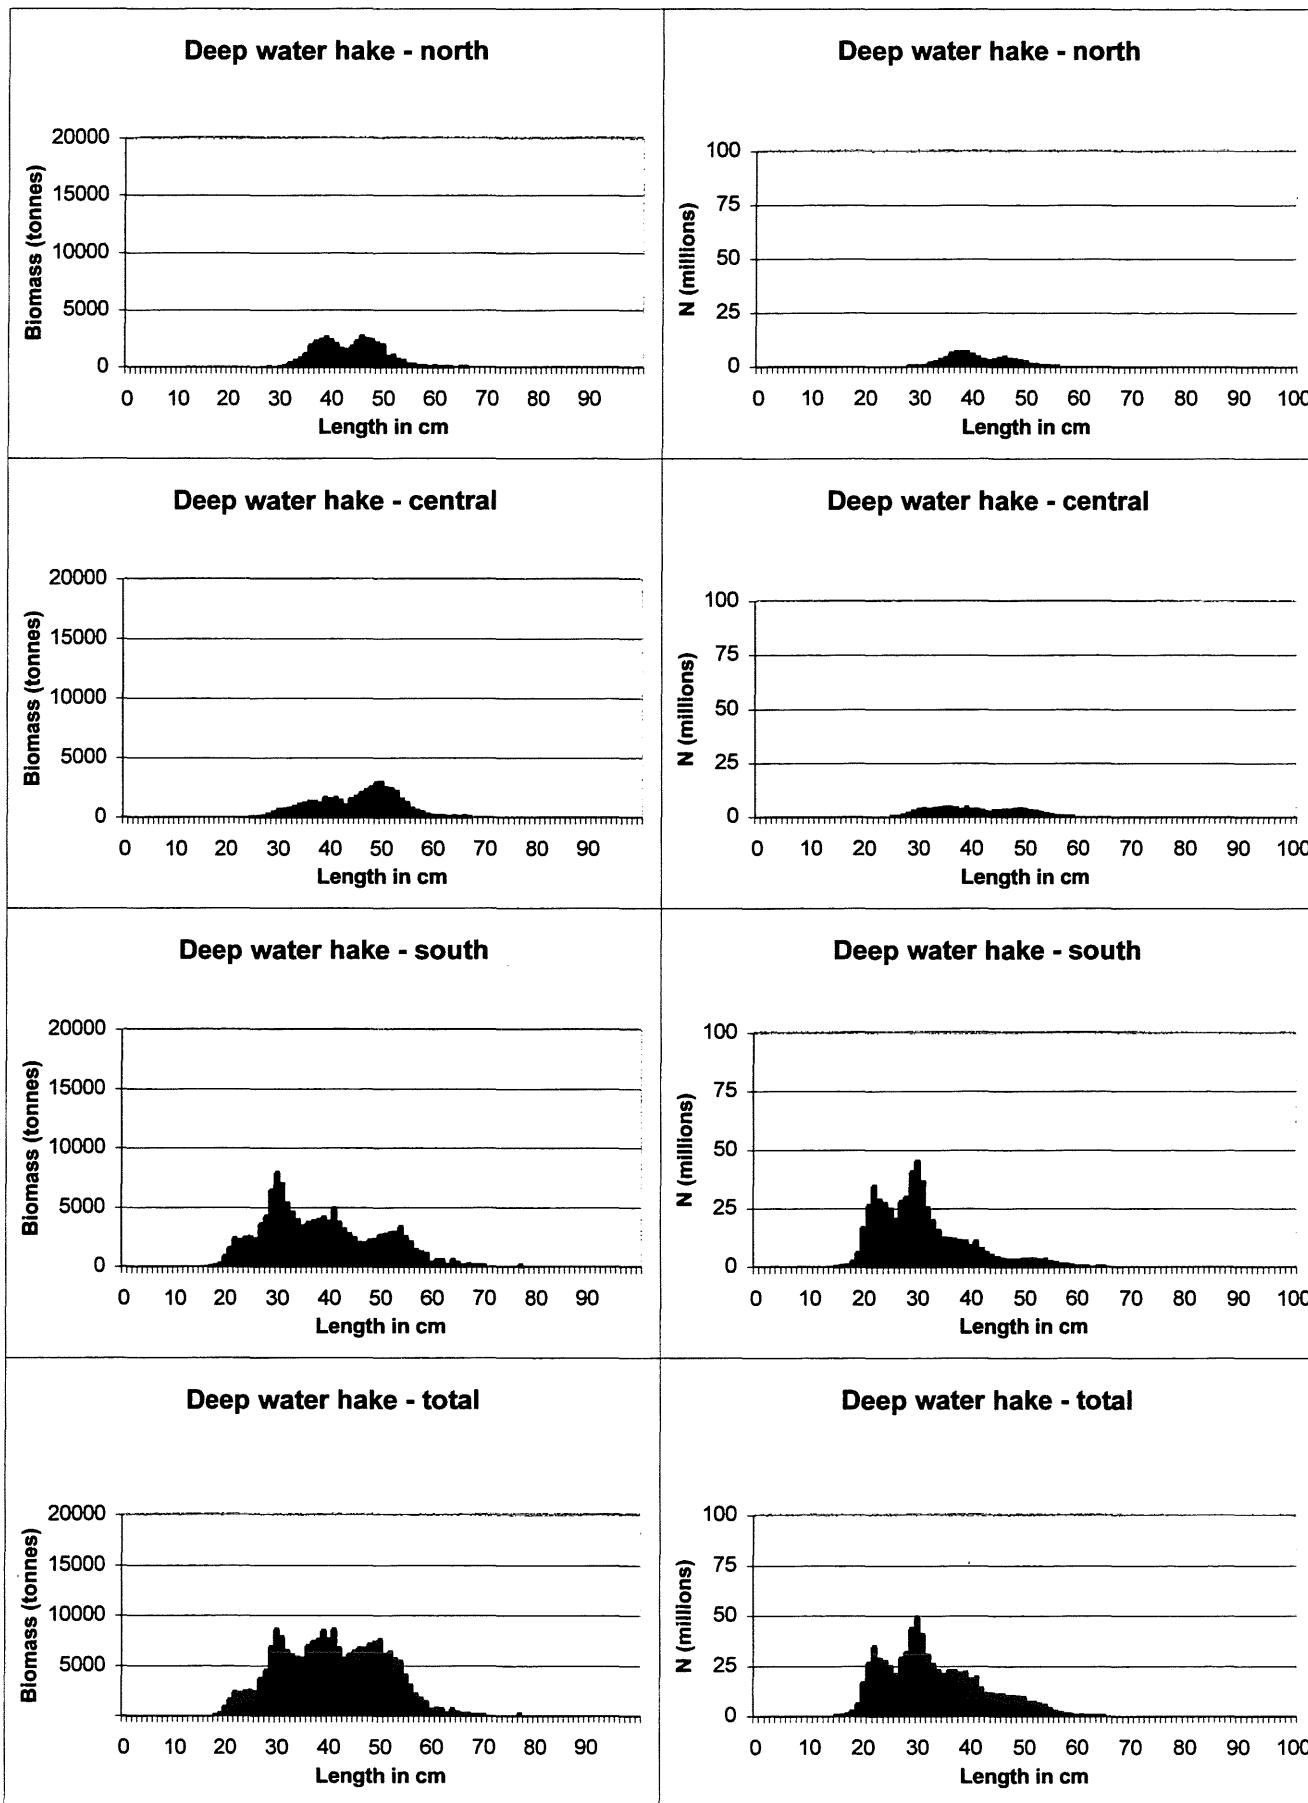

there was no significant difference, and DR. FRIDTJOF NANSEN had larger average haul biomass per 1000 m² (7.5) than AFRICANA (6.2) (Annex V, Table 1). This result coincides with a general impression that there is a shift towards higher apparent DR. FRIDTJOF NANSEN catches and lower AFRICANA catches from 1996 to 1997. As mentioned above this may partly be due to lower AFRICANA speed, leading to too high swept areas used in the computations, and partly to a greater emphasis on maintaining a better bottom contact on the DR. FRIDTJOF NANSEN.

Trawl geometry

The AFRICANA trawl rigging seems to induce a high and unrestricted door spread with a large sweeping angle. This will reduce trawl height, and will also cause variations in trawl parameters and consequently, swept area, with depth. One way of getting around this problem is to use warp restriction (strapping, see above, under Table 17). In the DR. FRIDTJOF NANSEN rigging this is used 130 m in front of the doors, giving a stable door spread of 54 m with 40 m bridles, and a stable height of 4.6 m, regardless of depth/warp length.

Annex I Six composition of main stocks

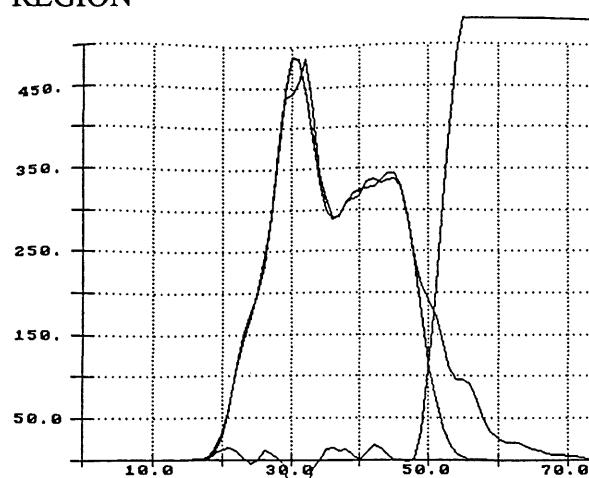

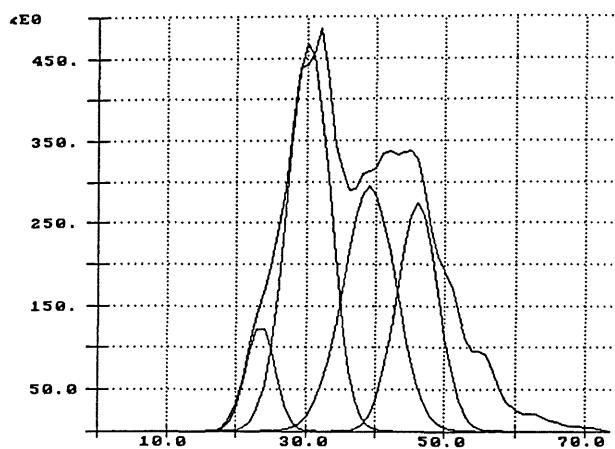

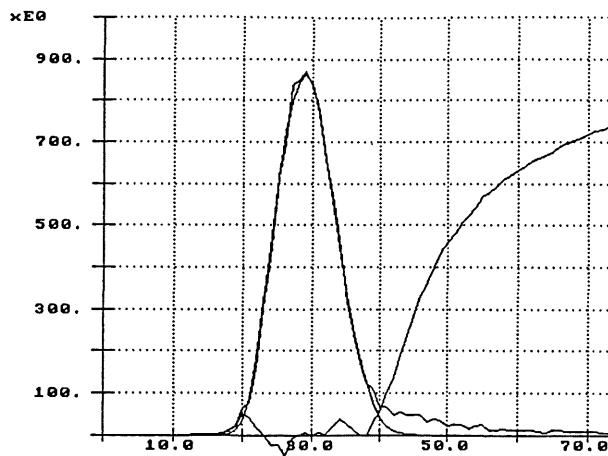

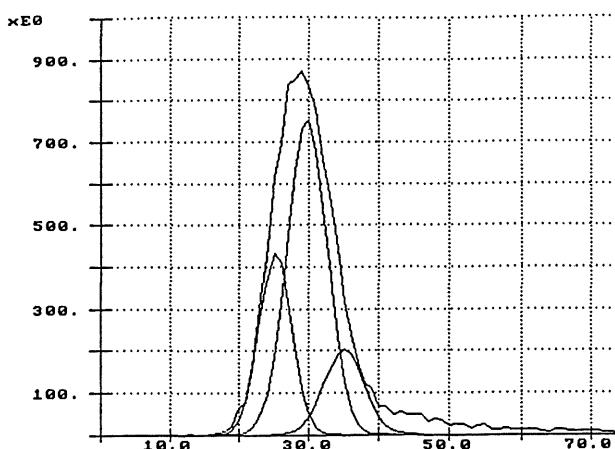

Annex II The size composition of the hake stocks split into length cohorts through optimizing techniques

CAPE HAKE

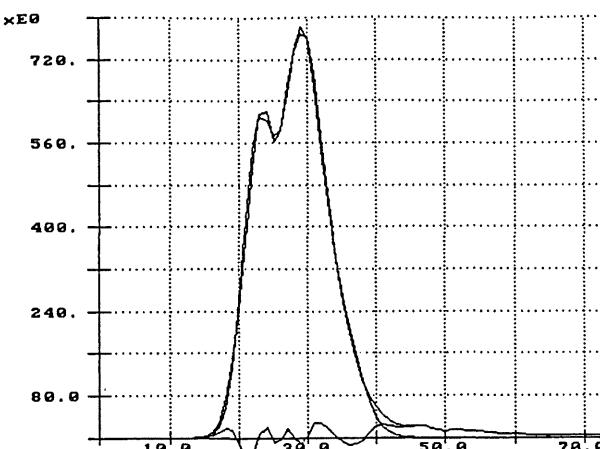

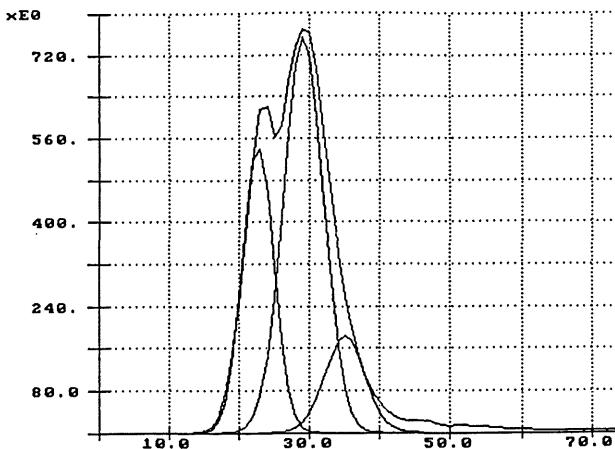

NORTHERN REGION

CENTRAL REGION

SOUTHERN REGION

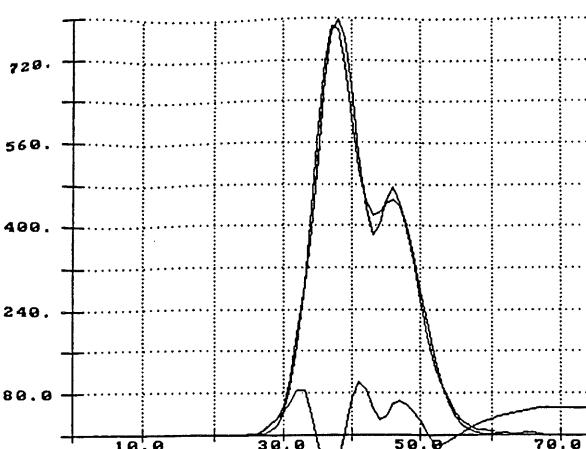

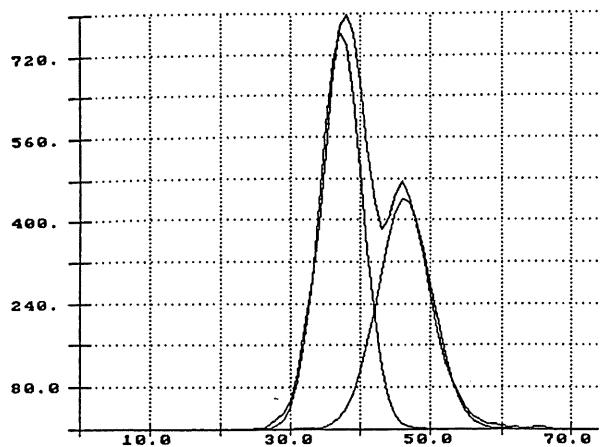

The length frequency distribution with the estimated cohorts.

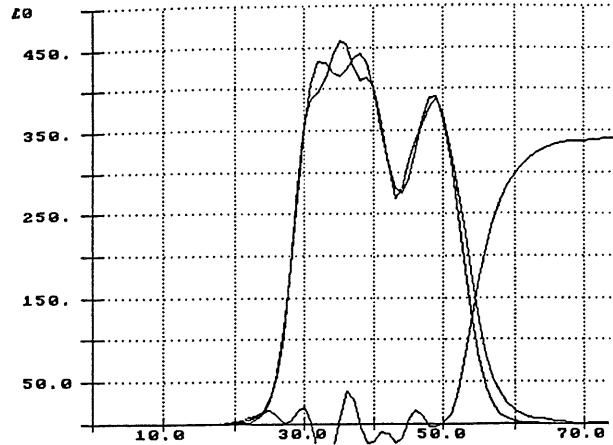

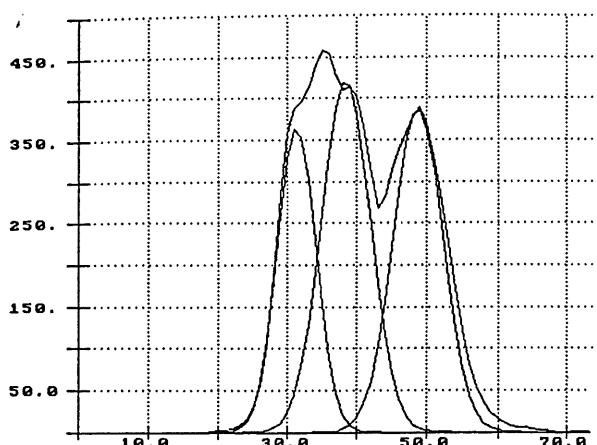

The length frequency distribution with the resultant distribution explained by the estimated cohorts.

DEEP WATER HAKE

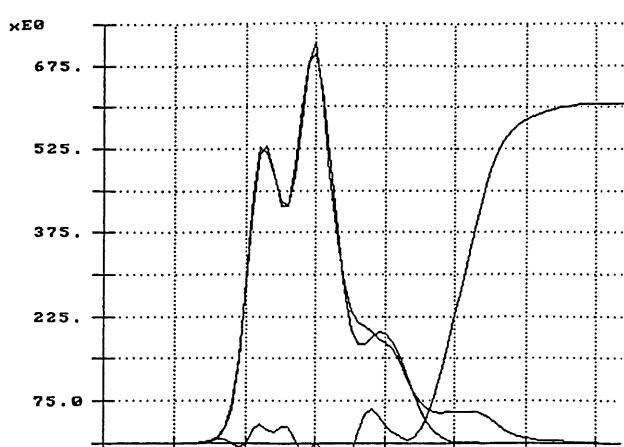

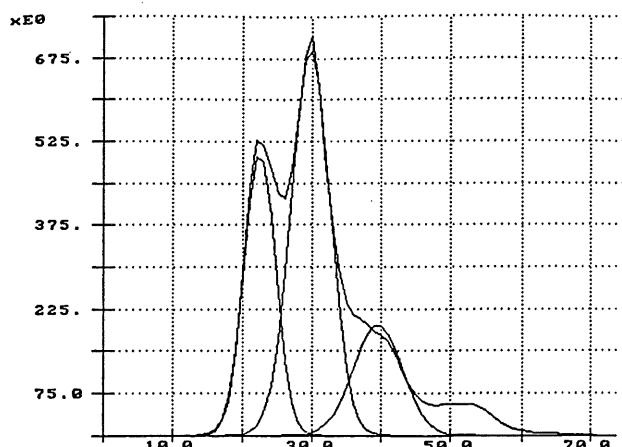

NORTHERN REGION

CENTRAL REGION

SOUTHERN REGION

The length frequency distribution with the estimated cohorts.

The length frequency distribution with the resultant distribution explained by the estimated cohorts.

Annex III Records of fishing stations

Annex IV Instruments and fishing gear used

Acoustic instruments

The SIMRAD EK500/38 KHZ scientific sounder was used during the survey for estimation of fish density. The EK500 has a built- in digital echo integrator, but the Bergen Echo Integrator system (BEI) was used throughout the survey. The details of the instrument settings are as follows:

Transceiver settings:

Bandwidth	Wide (3.8 KHz)
Pulse length	Medium (1 ms)
Max Power	2000 Watt
Sv Transducer gain	27.8 dB
Ts Transducer gain	28.1 dB

Printer settings:

Range	0 - 100 or 0 - 250 m
TVG	20 log R
TS Colour min	- 50 dB
Sv Colour min	- 64 dB

An ES38B with a 6.8° -3dB beamwith transducer was used for integration.

A calibration experiment using a standard copper sphere, performed in Baia dos Tigres 23/2 1994 gave the following results: Sv Transducer gain 27.8 dB, Ts Transducer gain 28.1 dB.

Glossary:

Sv Transducer gain: Peak transducer gain assumed during computation of volume backscattering strength.

Ts Transducer gain: Peak transducer gain assumed during computation of target strength.

Ts Colour min: Lower limit of colour scale relative to target strength.

Sv Colour min: Lower limit of colour scale relative to volume back scattering.

Hydrography

Conductivity, temperature, density and oxygen were sampled regularly at CTD stations with a Seabird CTD-sonde. The salinity was calculated by a computer.

Fishing gear

The vessel has two different sized 'Åkrahamn' pelagic trawls and one Gisund super bottom trawl. Only the bottom trawl was used during the survey.

The bottom trawl has a headline of 31m, footrope 47m and 20mm meshsize in the codend with an innernet of 10mm meshsize. The estimated headline height is 5m and distance between the wings during towing about 18m. The trawl is equipped with a 12" rubber bobbins gear and 7.8m², 1670kg 'Tyborøn' trawl doors. The sweeps are 40m long.

The following drawings show the size of these trawls.
