CHAPTER 5 REVIEW OF SURVEY RESULTS AND AVAILABILITY FOR FISHERY

5.1	Sardinella and horse mackerel	30
-----	-------------------------------------	----

Annex I	Records of fishing stations
Annex II	Length distributions of main species
Annex III	Instruments and fishing gear used
Annex IV	Estimation of age and growth, <i>Sardinella maderensis</i>
Annex V	Feeding habits, <i>Trachurus trecae</i>
Annex VI	Maturity tables for main pelagic species

CHAPTER 1 INTRODUCTION

1.1 Objectives

The objectives of the survey, previously agreed upon with the Director of the Instituto de Investigação Pesqueira (IIP) are the following:

- To map the distribution and estimate the abundance of the commercially important pelagic and semi-pelagic fish species in Angolan waters, including the two sardinella species *Sardinella aurita* and *S. maderensis*, the Cunene horse mackerel *Trachurus trecae*, the Cape horse mackerel *Trachurus capensis*, the pilchard *Sardinops ocellata* and other pelagic species, mainly carangids.
- To carry out biological studies on the main species, i.e. estimate the biological condition length weight-relationships and reproductive stages. A special study on horse mackerel diel vertical migration in relation to its feeding habits would also be carried out.
- Map the general hydrographic regime by using a CTD-sonde all over the survey area and monitor the temperature, salt and oxygen on IIP standard profiles for hydrographical studies.
- Conduct current measurements with ADCP system.
- On-the-job training for the Angolan participants on the main survey routines would be imparted, including scrutinizing the echograms and biomass estimation with the acoustic system.

The aim of these surveys is to build a time series to allow a better understanding of the fluctuations in the main pelagic stocks and of the main species biology.

1.2 Participation

The scientific staff consisted of:

From IIP, Angola: Filomena VAS VELHO, N'Kosi LUYEYE, Bomba BAZIKA, Agostinho DUARTE, Chores PINTO, Isaías JULIO, Kumbi KILONGO

From IMR, Bergen: Tore MØRK, Martin DAHL, Valentine ANTHONYPILLAI, Inge FOSSEN, Oddgeir ALVHEIM (25/2 to 4/3), Gabriella BIANCHI (5/3 to 21/3)

1.3 Narrative

The vessel left Luanda on 26 February and steamed to the Congo River estuary where the survey started. The shelf north of the Congo River was not covered because of restrictions due to oil drilling activities. The shelf was covered from close to shore (20 m depth) to beyond the 200 m isobath or to where no pelagic fish were recorded. The course track consisted of systematic triangular transects with endpoints about 15 NM apart. From about N'Zeto the course track changed to parallel transects, about 10 NM apart. CTD (Conductivity-Temperature-Depth) and ADCP (Acoustic Doppler Current Profiler) measurements were taken on standard hydrographical sections and along the course track. A call was made in Luanda on 5 March to exchange the cruise leader. The survey was resumed on 6 March and a complete coverage of the area Luanda-Benguela was carried out. The area was covered with parallel tracks, about 7 to 10 NM apart, from about 20 to just beyond 200 m depth. On 13 March the vessel called on Lobito for crew change. The southern region, between Benguela and Cunene, was covered in the period 14 to 18 March. The area between Benguela and Tombua has an extremely narrow and irregular shelf and the cruise track had a triangular, also rather irregular pattern. The shelf from Tombua to Cunene is wider and parallel transects were used, at a distance of about 5 NM. The vessel started steaming to Walvis Bay on 18 March and arrived on 20 March.

1.4 Survey effort

Figures 1a-c show the cruise tracks with fishing stations and the hydrographic profiles and Table 1 the number of hydrographic, pelagic and bottom trawl stations and distance surveyed in the three regions.

CHAPTER 2 METHODS

2.1 Hydrographic sampling

A Seabird 911 CTD plus was used to obtain vertical profiles of temperature, salinity and oxygen. Real time plotting and logging was done using the Seabird Seasave software installed on a PC. The profiles were usually taken down to a few metres above the bottom, but not deeper than 500 m.. Two Niskin bottles were triggered for water samples on each station, one near the bottom and one near the surface (5 m depth). This was done only in the CDT stations between Cabinda and Luanda. The samples were analysed for salinity using a Guildline Portasal salinometer, and the oxygen content was determined using the Winkler method. These laboratory values were used for calibration of the CTD after removing obvious outliers. Because of a technical problems with the salinometer, no calibration was possible for the rest of the survey. Therefore, salinity values presented here are taken from the CTD without any correction.

For oxygen 46 samples were accepted for the calibration. A linear regression gave the following formula for correcting the oxygen values:

$$O_2 = O_{2ctd} * 1.0985 + 0.0911$$

The standard deviation of the calibration was 0.47.

ADCP current measurements

A ship born Acoustic Doppler Current Profiler (ADCP) from RD Instruments was activated on every CTD station with bottom depths greater than about 25 m. The ADCP was set to ping every 8 seconds, the depth cell was chosen to 8 m and the number of cells to 50. As a routine the data were averaged over 300 seconds for analyses onboard. Both the raw and averaged data were stored on files. The data were analysed by the PC software UMS (Underway Mapping System).

Meteorological observations

Wind (direction and speed), air temperature, global radiation and sea surface temperature (5 m depth) were logged automatically every nautical mile using an Anderaa meteorological station.

2.2 Fish sampling

Abundance estimation

The catches were sampled for species composition, by weight and numbers. Biological samples, i.e. length and weight compositions were taken for the target species. Records of fishing stations are presented in Annex I. Pooled length frequency distributions of selected species by area, are shown in Annex II.

A description of the acoustic instruments and their standard settings is given in Annex III. This also includes a description of the fishing gear used.

The following target strength (TS) function was applied to convert s_A -values (mean integrator value for a given area) to number of fish (pilchard, sardinella and Cunene horse mackerel):

$$TS = 20 \log L - 72 \text{ dB} \quad (1)$$

or in the form $C_F = 1.26 \cdot 10^6 \cdot L^{-2}$ (2)

where L is total length and C_F is the fish conversion factor. The following formula was used to calculate the number of fish in length groups (cm) for each fish concentration:

$$N_i = A \cdot s_A \cdot \frac{p_i}{\sum_{i=1}^n \frac{p_i}{C_{Fi}}} \quad (3)$$

where: N_i = number of fish in length group i

A = area (naut.miles²) of fish concentration

s_A = mean integrator value in area (A)

p_i = proportion of fish in length group i in samples from the area

C_{Fi} = fish conversion factor for length group i

The number per length group (N_i) was then summed and the total number of fish obtained:

$$N = \sum_{i=1}^n N_i \quad (4)$$

The length distribution of a given species within an area was computed by weighing the length

frequencies obtained in each trawl sample within the area by the average s_A value attributed to that species in the 5 mile where the sample was taken.

In the case of co-occurrence of *Sardinella aurita* and *S. maderensis* (these species cannot be separated in the echo traces), the respective contribution to the s_A value attributed to the 'sardinella' category was split in accordance with their presence in weight in the trawl catches. The biomass of fish per length group (B_i) was calculated by applying their condition factor observed mean weights per length group (\bar{W}_i) multiplied by number of fish in the same length groups (N_i). The total biomass in each area was obtained by summing the biomass of each length group:

$$B = \sum_{i=1}^n N_i \bar{W}_i \quad (5)$$

The number and biomass per length group in each concentration were at last summed to obtain the totals for each region. The mean integrator values in each sampling unit (s_A -values) were divided between the following categories of fish on the basis of trawl catches and characteristics of the echo traces:

- sardinella (*S. aurita* and *S. maderensis*)
- horse mackerel (*T. trecae* and *T. capensis*)
- pilchard
- round herring
- anchovy
- big-eye grunt (*Brachydeuterus auritus*)
- P2 (carangids, scombrids, barracudas and hairtails)
- other demersal fish
- plankton

Biological sampling

Total length and body weight were recorded for sardinella and horse mackerel to the nearest 1 cm or 1 g below, respectively. Sex and reproductive stages were described by macroscopic examination, scoring each individually sampled fish according to the following categories:

1	Juvenile
2	Inactive
3	Active
4	Ripe
5	Running/ Spent

Stomachs were taken of horse mackerel for a study of the feeding habits of this species in relation

to the observed diel vertical migrations. Ten stomachs per length group of 5 cm were taken at each station where the species occurred. Prey identification was limited to the main taxonomic groups: copepods, euphasiids and fish. This latter category was identified to the lowest possible taxonomic level.

CHAPTER 3 OCEANOGRAPHIC CONDITIONS

Surface distribution

Figures 2 a and b show the horizontal distribution of temperature and salinity, respectively, for the region between the Congo River and Pta das Palmeirinhas. Highest temperatures ($T > 28^{\circ}\text{C}$) were found in the northern part, with increasing values offshore. Pockets of relatively cold water ($T < 23^{\circ}\text{C}$) were found off Ambriz and north of Luanda, possibly due to local upwelling. The distribution of salinity shows a similar pattern, with low salinity water particularly in proximity of the Congo River estuary, and increasing values towards the south. The highest salinity values were found off Ambriz ($S > 35.5\text{‰}$), confirming that upwelling or mixing processes occur in this region.

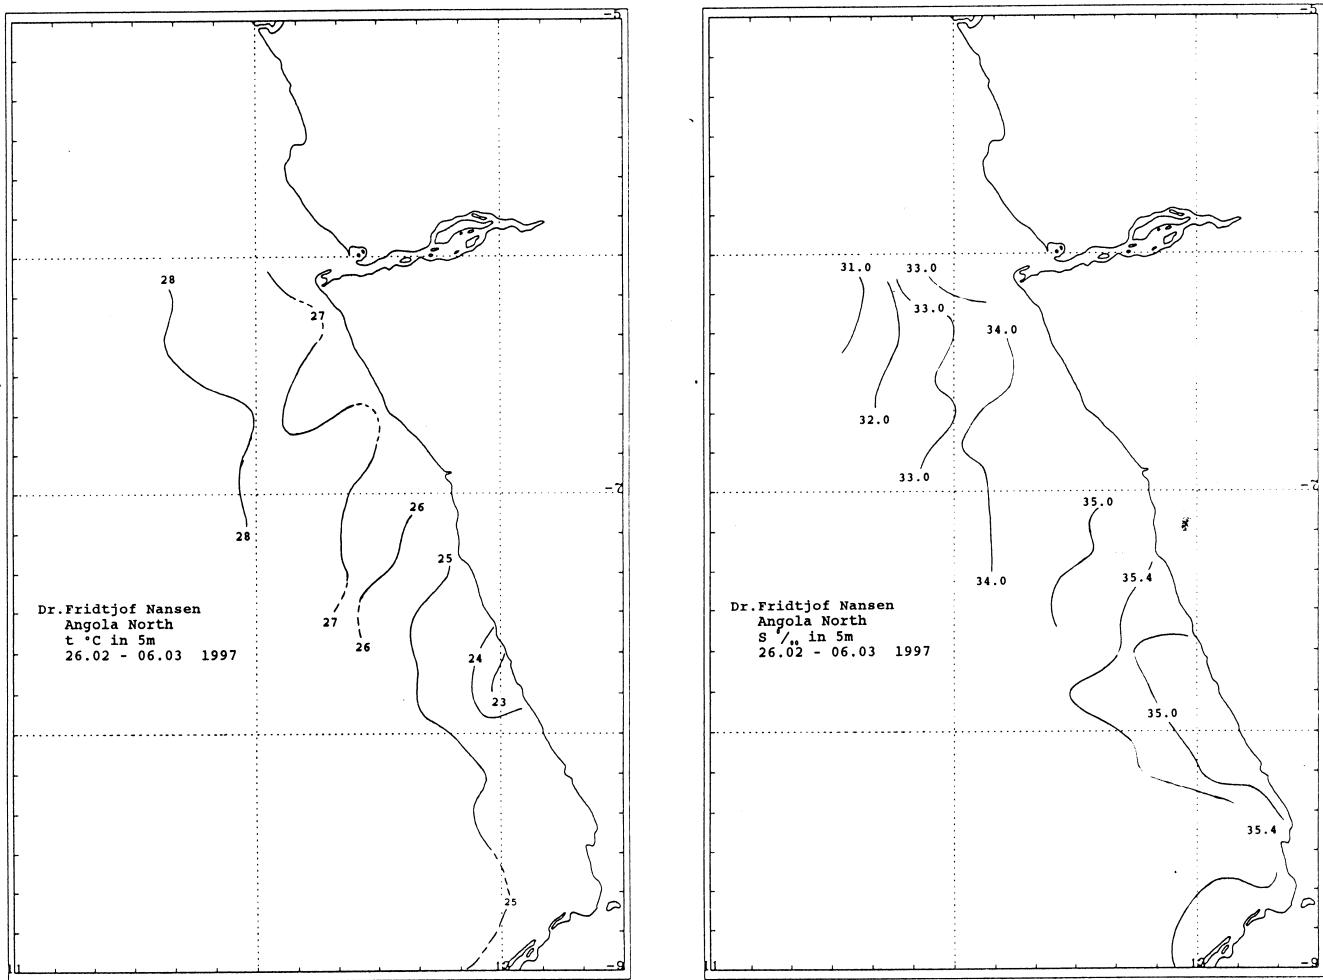

Figure 2. Horizontal distribution of temperature($^{\circ}\text{C}$) and salinity (‰), Congo River - Pta das Palmeirinhas

In the area Pta das Palmeirinhas-Benguela (Fig 3 a and b) there was a similar pattern of increasing temperatures from the coast and offshore. Lowest temperatures were encountered just south of

Pta das Palmeirinhas with values below 23°C, off Pta do Morro and south of Cabeça da Baleia ($T < 24^\circ\text{C}$). Salinity values appeared to be quite uniform at the surface (ranging from 35.4 to 35.9‰) and thus much higher than in the northern part where they ranged from 31 to 35.4‰. In the region between Tombua and the Cunene River surface waters become quite cold, down to 17.9 °C in Baias dos Tigres. There is a gradient of increasing temperatures from the coast to offshore, indicating an upwelling process in this region (Figure 4).

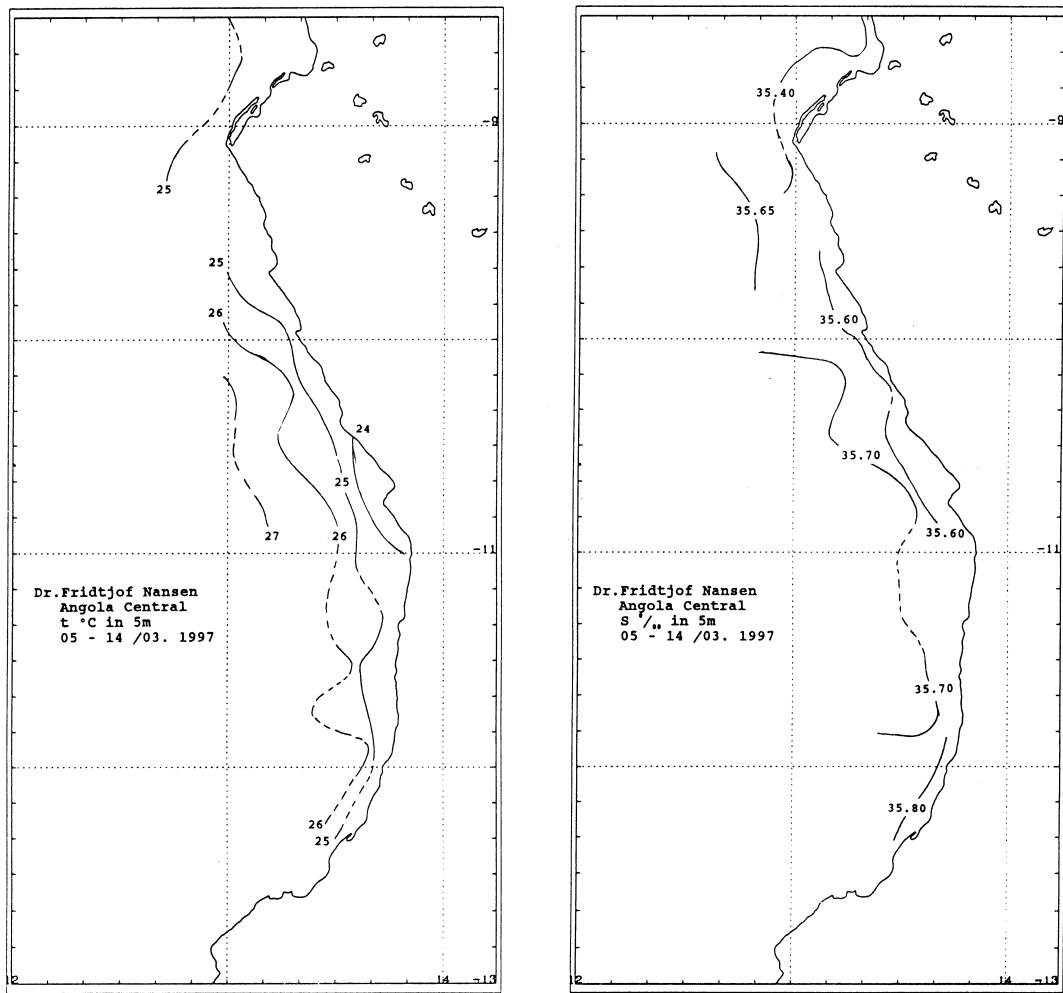

Figure 3. Horizontal distribution of temperature($^\circ\text{C}$) and salinity (‰), Pta das Palmeirinhas - Benguela

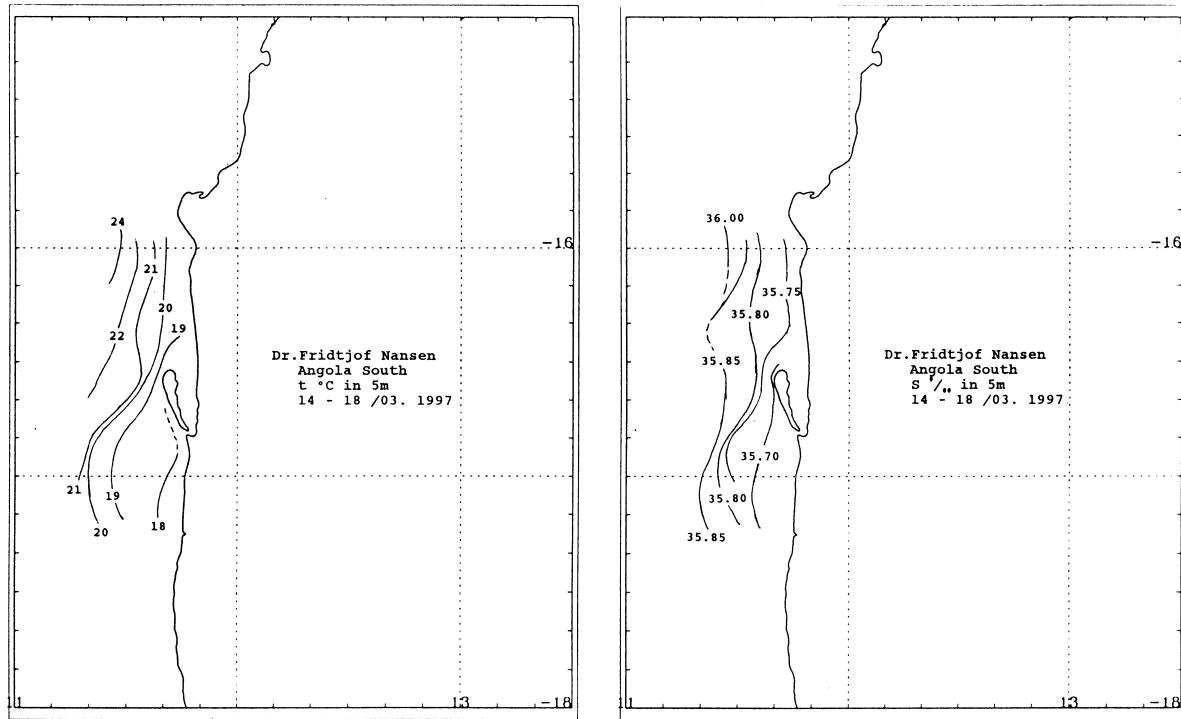

Figure 4. Horizontal distribution of temperature($^{\circ}\text{C}$) and salinity (‰), Tombua - Cunene

Vertical distribution

The vertical distributions of temperature, salinity and oxygen along the standard sections are shown in Figures 5 a-g.

The northernmost section (Pta da Moita Seca, Fig 5a) shows the presence of a stable layer of warm and brackish water, originating from the outflow of the Congo River. Off Ambriz (Fig.5 b) the conditions are more dynamic and the surface layer is broken toward the coast by a possible upwelling process. This confirms the image produced by the horizontal distributions of temperature and salinity discussed above. Signs of slight upwelling were found off Pta das Palmeirinhas, as shown by the horizontal temperature distribution, although so feeble that are not visible in the vertical section. The section at Pta do Morro on the contrary shows clear signs of vertical water displacement toward the surface, both in the temperature and oxygen values. In the southern region (Tombua-Cunene) there was an autumn situations, with clear signs of coastal upwelling throughout. Low oxygen levels (<2m/l) were already found at about 50 m depth.

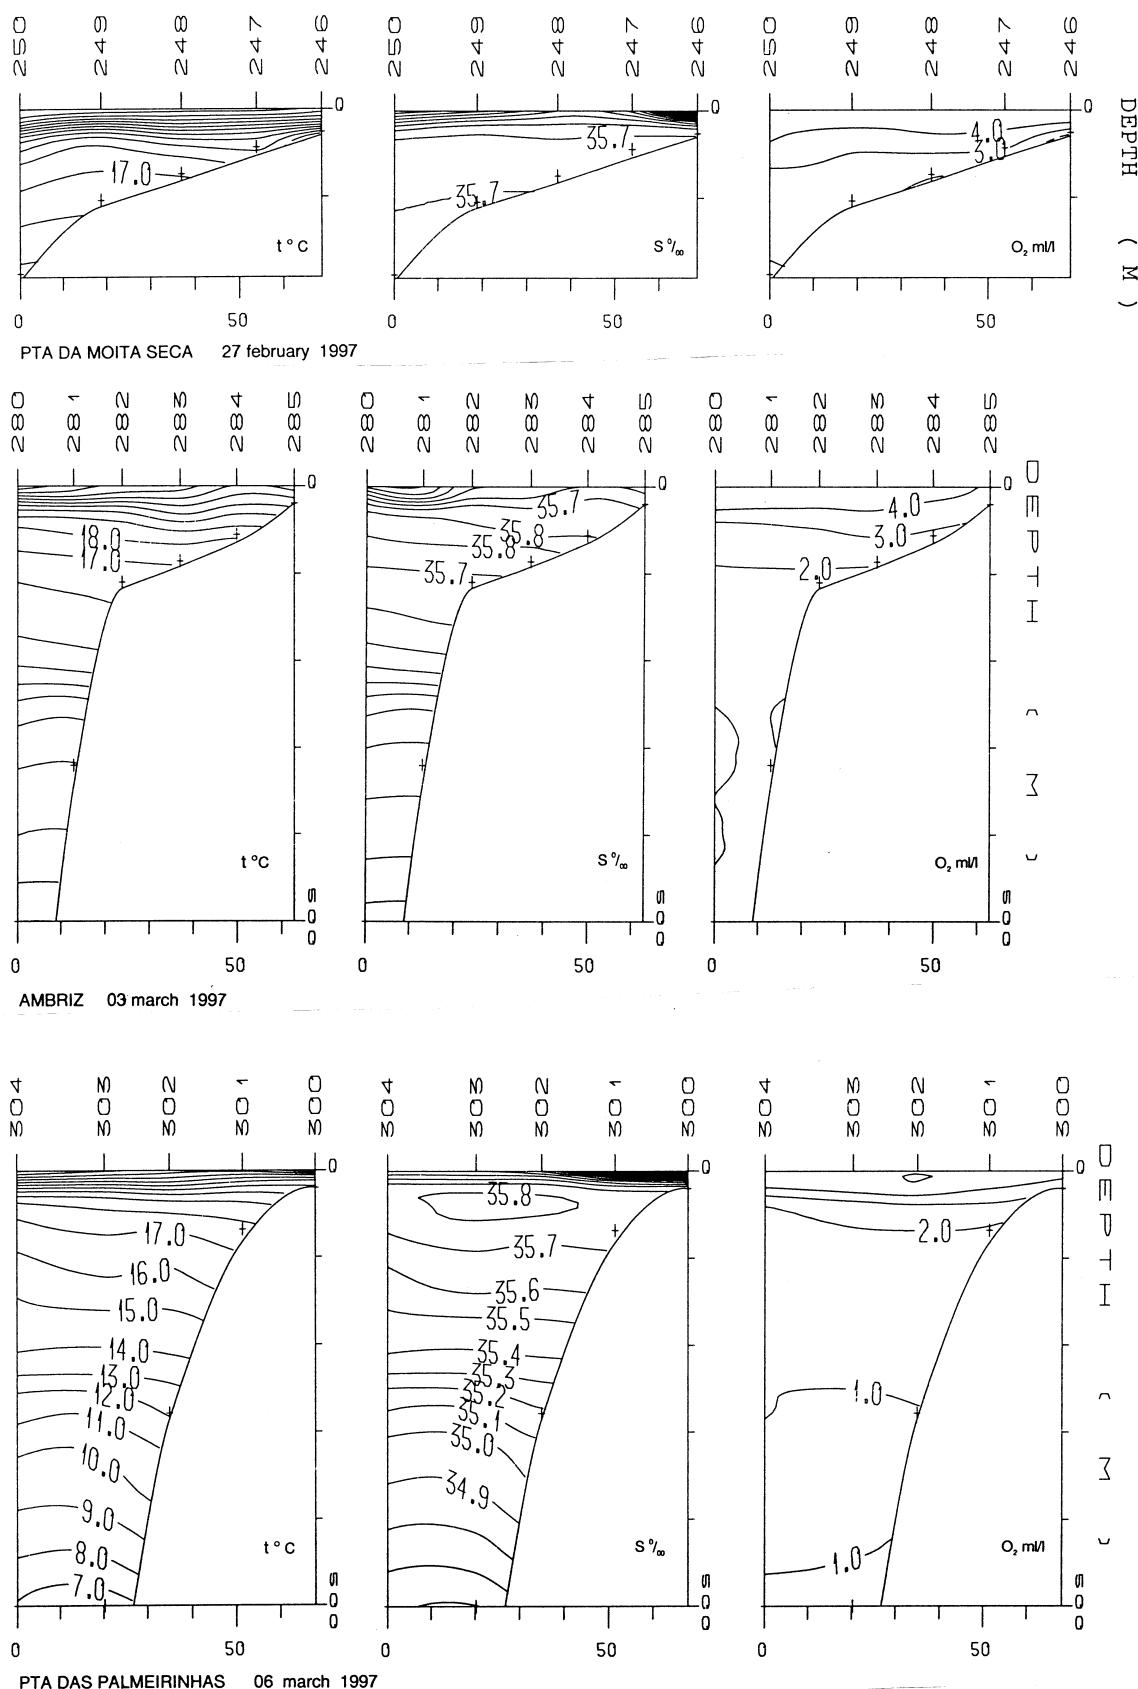

Figure 5 . Vertical profiles of temperature($^{\circ}\text{C}$), salinity (\%_o) and oxygen(ml/l)

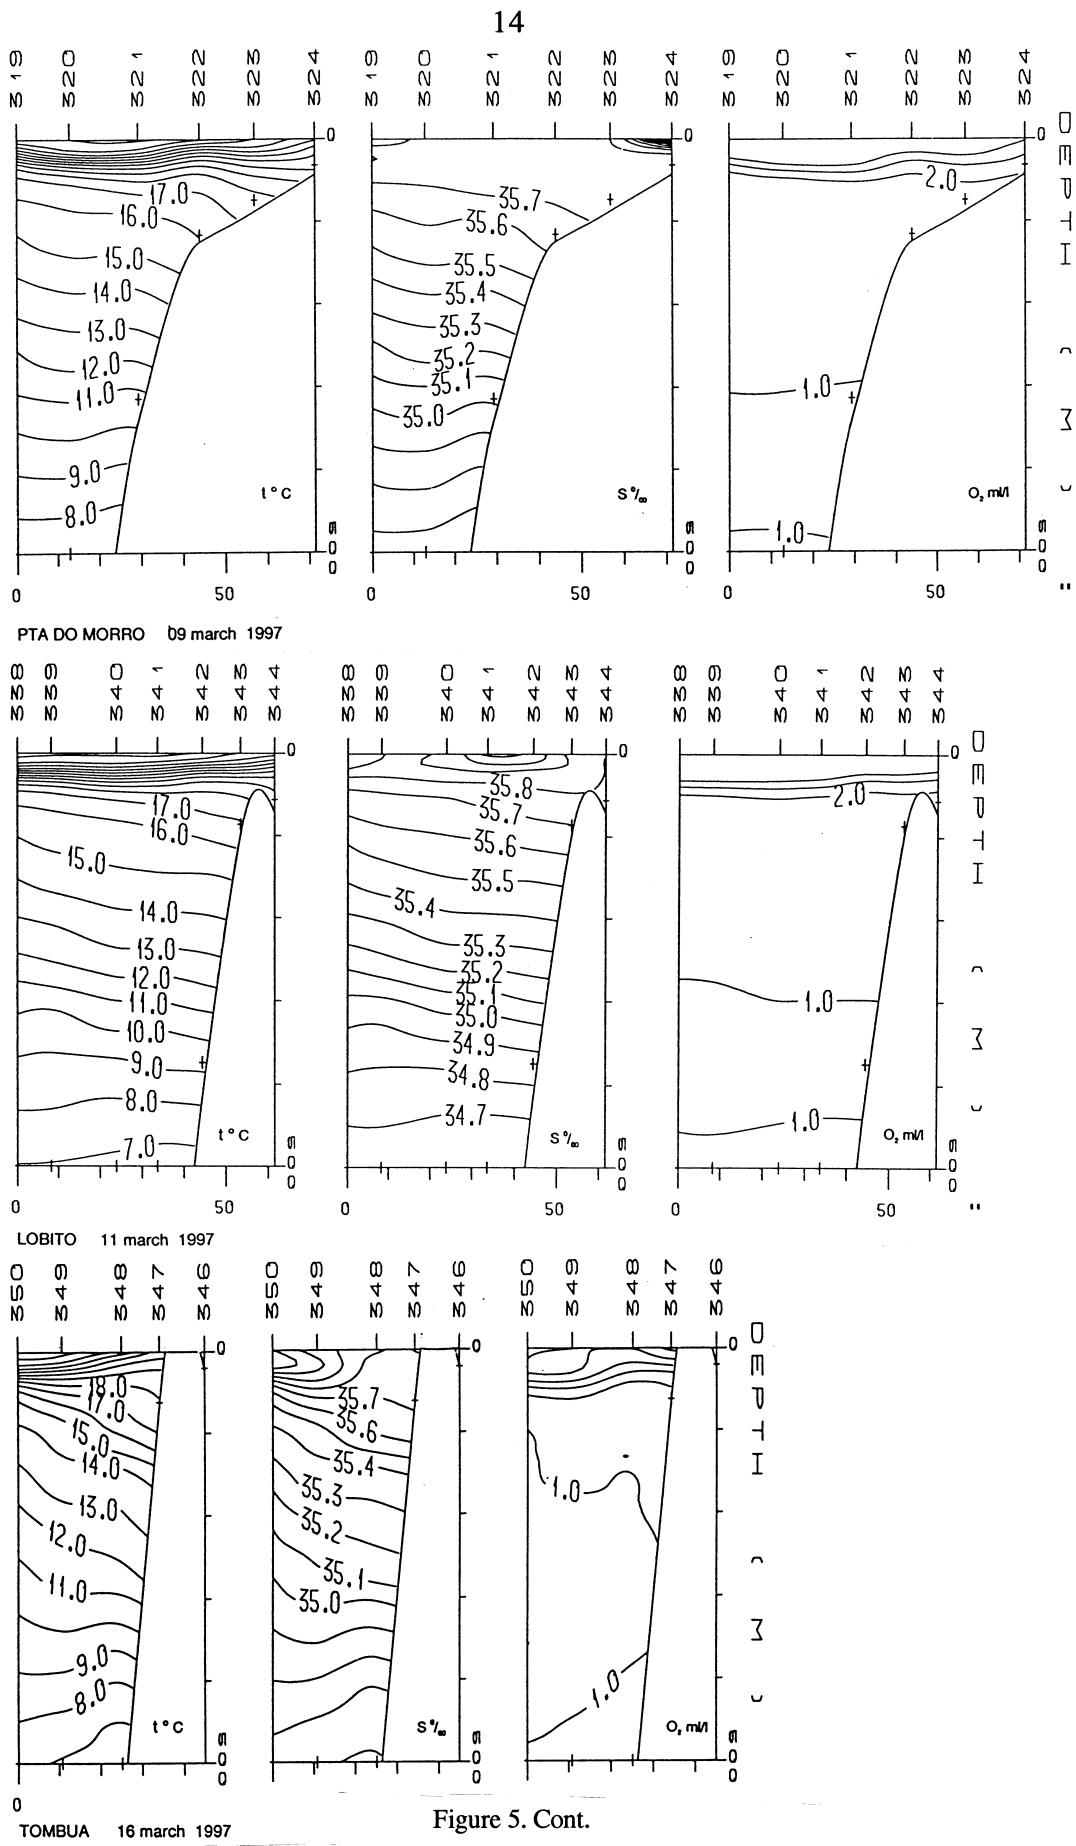

Figure 5. Cont.

In general, 1997 appears to be the coldest in the series collected by the RV 'Dr. F. Nansen' since 1994. Cooler waters are found to a depth of about 170 m while the values do not diverge much at greater depths. Salinity values are also higher than usual in surface waters. Oxygen levels at surface waters are higher than in previous years but substantially lower in subsurface layers, which indicates the vertical displacement of deep waters. Both halocline and oxycline were located at shallower depths as compared to 1995 and 1996, at about 5-15 m in the northern region and 25-35 m in the central region (Lobito). Figure 6 (a,b and c) show the vertical profiles at selected stations from the transects off Ambriz, Pta das Palmeirinhas and Lobito, respectively, to compare the present with the last year situation, in the same period. Also in the southern region, Tombua to Cunene, surface temperatures were much lower than in 1996, ranging between 17.9 to 22.0°C against 26 to 28 °C of last year. The present condition indicates the onset of the autumn season and should be considered as normal.

LOBITO

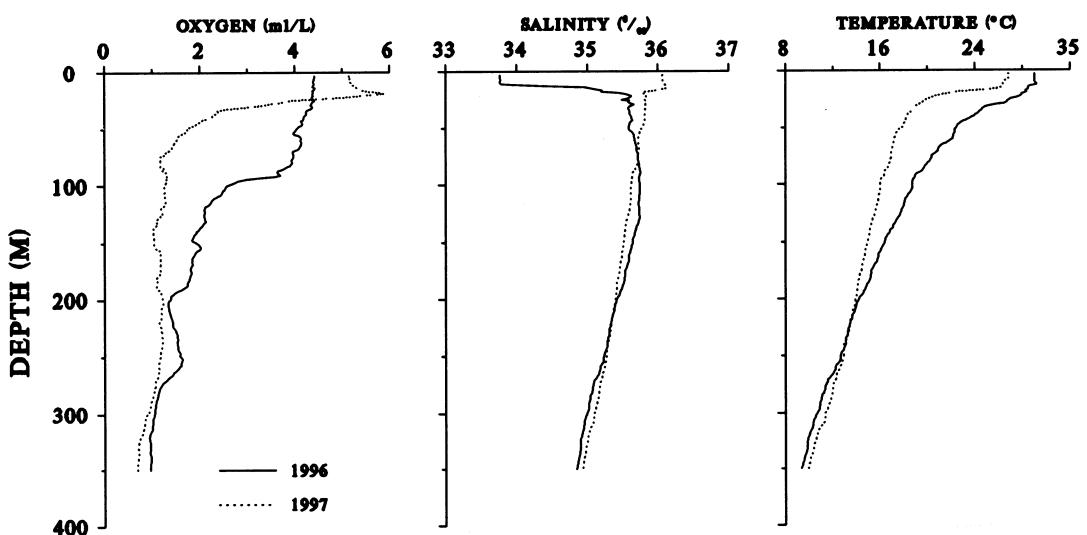

Figure 6. Cont.

CHAPTER 4 DISTRIBUTION, COMPOSITION AND BIOMASS ESTIMATES OF PELAGIC FISH

4.1 Congo River - Pta das Palmeirinhas

As in earlier surveys, the northern region, north of the Congo River estuary, was not covered because of oil extraction activities. The entire exclusion of this area from the survey coverage started with the August-September survey in 1995.

4.1.1 Sardinella

Both species (*Sardinella aurita*, the round sardinella, and *Sardinella maderensis*, the flat sardinella) were found in shelf waters from the Congo River to Pta das Palmeirinhas, with highest concentrations in the shallow area between N'Zeto, Ambriz and off Pta das Palmeirinhas. Figure 7 shows the distribution of both sardinellas for the northern region, including the varying degree of their concentrations as average acoustic integrator values for each area. This distribution coincides with the area of lower surface temperatures and higher surface salinity values (see Chapter 3) found in this region. These values indicate water mixing processes or upwelling, that generate conditions more suitable for pelagic fish.

The two species were usually mixed in the catches. The round sardinella consisted mainly of juveniles and young, with modes of 15 and 23 cm (Fig. 8 a). Its highest concentrations were found just north of N'Zeto and off Ambriz. The biomass of this species was estimated to 90 000 tonnes.

The flat sardinella (Fig. 8 b) was represented by young with lengths between 12 and 23 cm and a mode of 17 cm. Larger specimens (mode 28 cm) were also present but their abundance was much smaller. The biomass of flat sardinella was estimated to about 120 000 tonnes.

Compared with the results obtained in March last year, the biomass estimates for this region are significantly higher for both species. In 1996 the flat sardinella was estimated to 65 000 tonnes, with a similar length distribution as compared to this year, and the round sardinella was estimated to 5 000 tonnes and consisted mainly of large individuals. The former species has shown an increase of about 55 000 tonnes, while the latter is now present at a level of 90 000 tonnes, mostly consisting of young specimens. Although in this report the estimates for the northern region also include the area between Luanda and Pta das Palmeirinhas (contrary to earlier reports) this concentration totalled 21 000 tonnes for the flat sardinella and only 3 000 tonnes for the round

sardinella, which does not influence the overall conclusion that there is an increase in the biomass of both species in this area. (See Chapter 5 for further discussion on comparisons with earlier years).

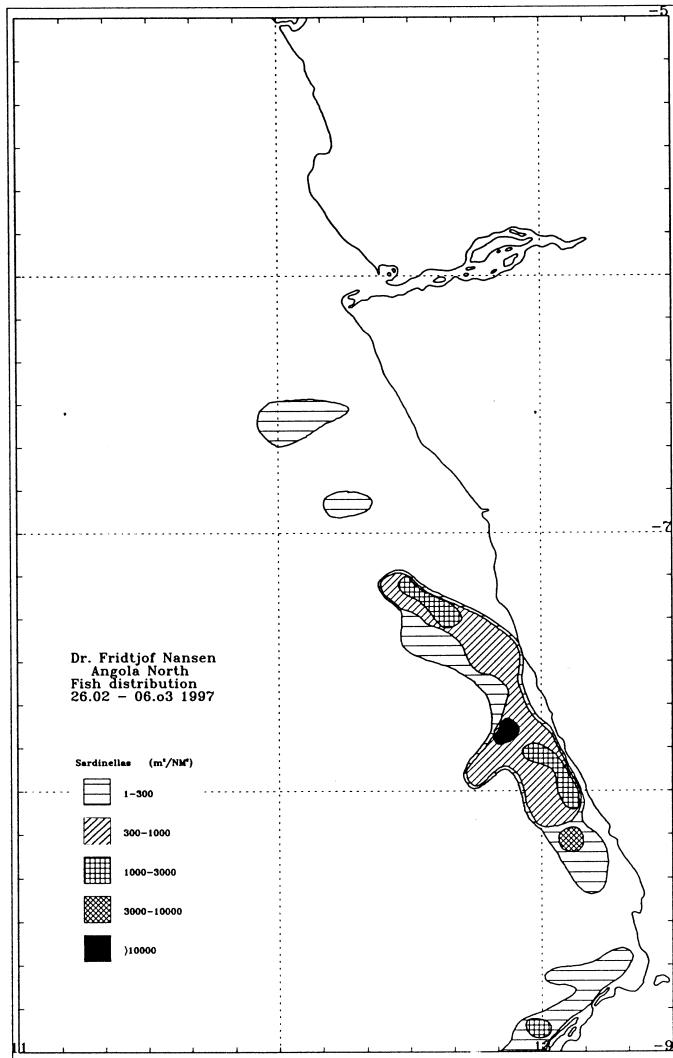

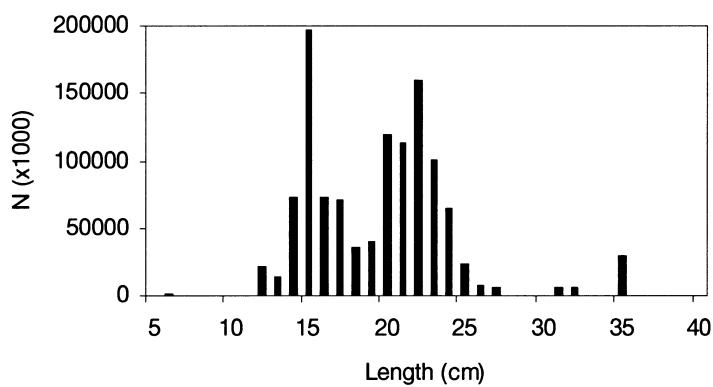

Figure 7. Distribution of *Sardinella* spp. Congo River-Pta das Palmeirinhas

a) *Sardinella aurita*

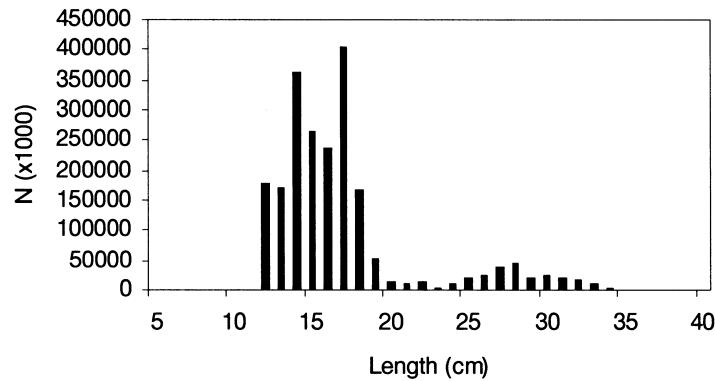

b) *Sardinella maderensis*

Figure 8. Total length distribution of a) round sardinella (*S. aurita*) and b) flat sardinella (*Sardinella maderensis*). Congo River-Pta das Palmeirinhias

4.1.2 Cunene horse mackerel

Figure 9 shows the distribution of horse mackerel for the region from off the Congo River estuary to Pta das Palmeirinhias. The species was widely distributed in this region, occupying also the shallower parts of the shelf south of N'Zeto. The densities were usually low, except for two small areas off N'Zeto, south of Ambriz and between Luanda and Pta das Palmeirinhias, respectively. Figure 10 shows the length distribution of horse mackerel for the whole region. Young fish with a mode of 18 cm dominated, followed by two cohorts with modes of 32 and 46 cm. The young fish was distributed over the whole shelf to Luanda, while the adult fish was in the Pta das Palmeirinhias area. The total biomass of horse mackerel in this region was estimated to about 138 000 tonnes. Compared to the last year estimate for this region (6 000 tons), it appears that, as for the round sardinella, there is a massive increase, particularly of young fish.

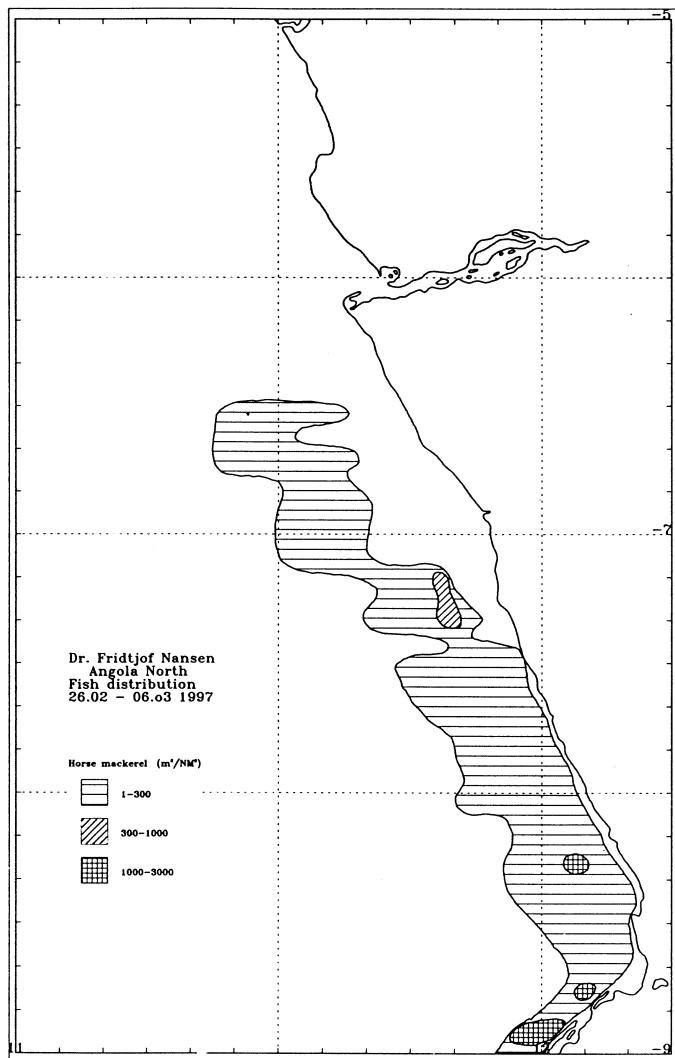

Figure 9. Distribution of Cunene horse mackerel (*Trachurus trecae*). Congo River - Pta das Palmeirinhas

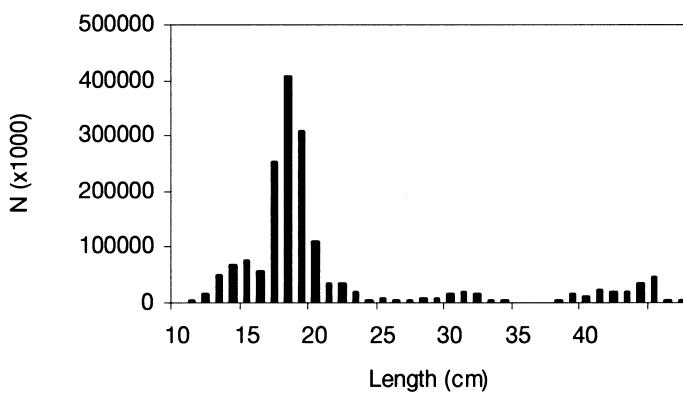

Figure 10. Estimated abundance of Cunene horse mackerel (*Trachurus trecae*) by length groups. Congo River - Pta das Palmeirinhas

4.1.3 Other pelagic species and big-eye grunt

This category includes a large number of pelagic species of the families Carangidae, Sphyraenidae, Trichiuridae, and Scombridae, usually mixed in a highly diverse pelagic community. This makes the abundance estimation with the acoustic system, at species level, practically impossible. For this reason all these species are treated together to give an idea of the order of magnitude of these resources, but the estimate should be considered as very rough. Figure 11 shows the distribution of pelagic fish type 2 for the region and Table 2 shows the catch rates of the main categories included in this group (sardinella and horse mackerel are not included). Highest concentrations were detected in the shallow waters between Pta da Moita Seca and Cabeça da Cobra and between N'Zeto and Ambriz. The biomass estimate was obtained by using an overall average length (about 30 cm) for this area and resulted in a value of about 140 000 tonnes. The composition in the catches shows a dominance of Carangidae (*Selene dorsalis* and *Chloroscombrus chrysurus*) followed by hairtail (*Trichiurus lepturus*), both in the shallow inshore waters as well as over the edge of the shelf. This group includes several species of commercial importance, particularly for small scale fisheries.

4.2 Luanda-Benguela

4.2.1 Sardinella

Both species were found throughout the area, in the inner part of the shelf, with highest concentrations off Pta do Morro and between Lobito and Cabeça da Baleia. The highest concentrations were found at about in a band along the coast, at about 40 m depth, in the southern part of the area. Figure 12 shows the distribution for this region of the species combined, with an indication of their relative densities. The length distributions showed two main modes for the flat sardinella at 23 and 33 cm. For the round sardinella the length distribution is

less clear, with one clear mode at 23 cm, while for the rest of the distribution is difficult to identify possible cohorts. Biomass estimates showed that the flat sardinella is still dominating, but the relative abundance of the round sardinella is increasing in comparison with previous years. Present estimates indicated about 150 000 tonnes for the former species and about 45 000 tonnes for the latter.

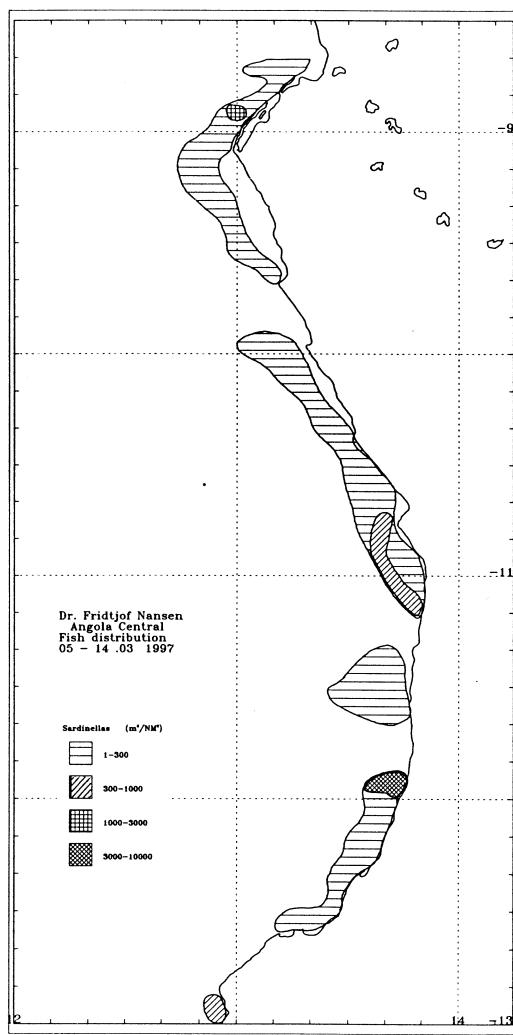

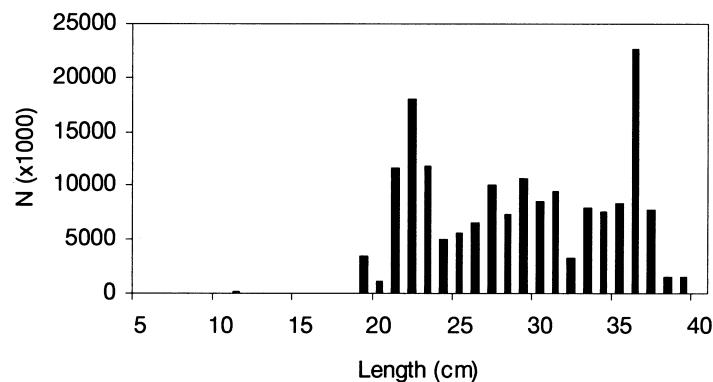

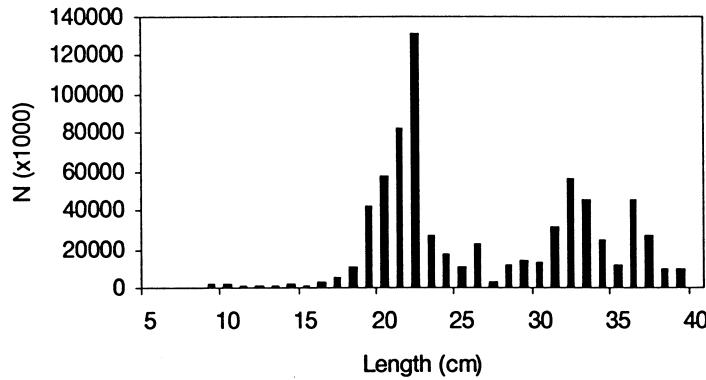

Figure 12. Distribution of *Sardinella* spp. Pta das Palmeirinhas - Benguela

b) *Sardinella maderensis*

Figure 13. Total length distribution of a) round sardinella (*S. aurita*) and b) flat sardinella (*Sardinella maderensis*).
Pta das Palmeirinhas - Benguela

4.2.2 Cunene horse mackerel

Horse mackerel were evenly distributed over most of the inner shelf in this region (Figure 14). Larger concentrations were found closer to the coast and particularly between Cabeça da Baleia and Benguela.

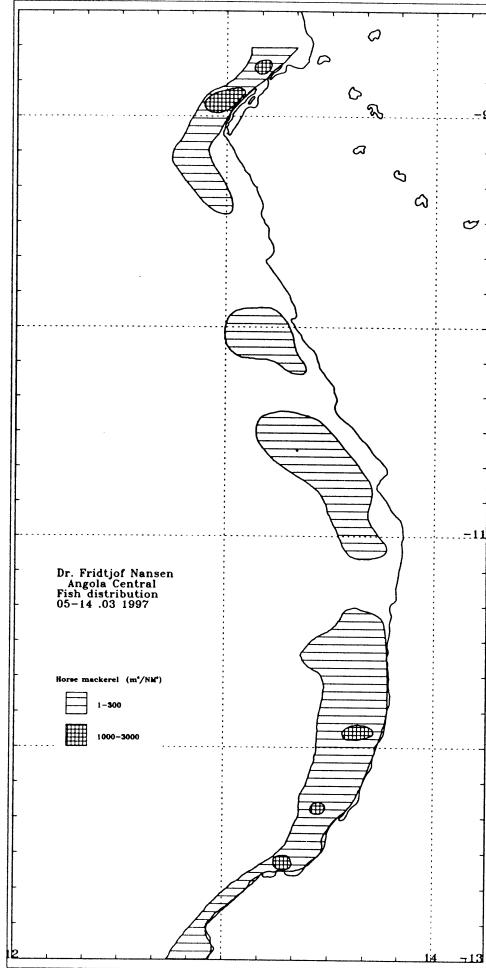

Figure 14. Distribution of horse mackerel (*Trachurus trecae*), Pta das Palmeirinhas - Benguela

The vertical distribution was very much the same as was observed north of Luanda, dense schools close to bottom at daytime and dispersal and concentration of single fish near the surface during the night. The length distribution (Fig. 15) shows that juvenile fish dominates, with a mode of 14 cm. Adult fish shows a mode of 34 cm while intermediate cohorts are barely visible. The biomass estimate for the species was about 55 000 tonnes.

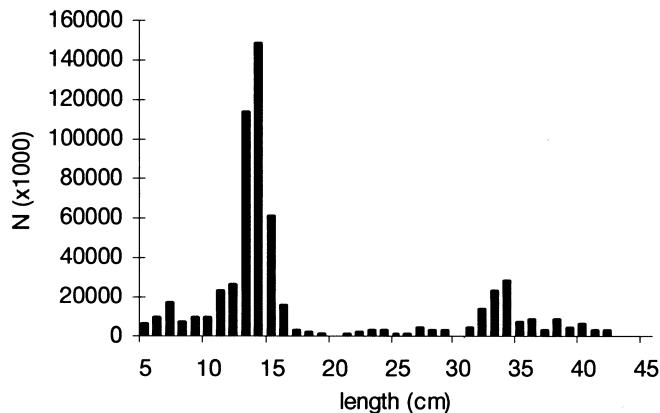

Figure 15. Total length distribution of horse mackerel (*Trachurus trecae*), Pta das Palmeirinhas-Benguela.

4.2.3 Other pelagic species and bigeye grunt

Figure 16 shows that pelagic species type 2 were widely distributed in this region from shallow coastal waters to beyond the edge of the continental shelf. Dense concentrations were found off Pta do Morro and in the Lobito-Benguela area. Large-size hairtail, up to 100 cm TL, appeared to be quite abundant. This species, appreciated in Angola as foodfish, was abundant both inshore and offshore, pelagic and near the bottom. Carangids were almost as abundant (Table 3) and consisted mainly of *Selene dorsalis* and *Chloroscombrus chrysurus*. The estimated biomass totalled about 130 000 tonnes, using an average length of 30 cm.

The big-eye grunt (*Brachydeuterus auritus*) was found in the areas with highest concentrations of pelagic fish (Fig. 17). Although belonging to a typically demersal family (Haemulidae) this species follows the diel migration pattern of pelagic species and is found near the surface during nighttime. During daytime it forms loose concentrations close to the bottom. A biomass estimate was attempted based on the acoustic registrations. With an average length of 18 cm and a condition factor of 1.36, the biomass was estimated at about 30 000 tonnes.

4.3. Benguela - Cunene

4.3.1 Horse mackerels

In this area two species overlap, the Cunene horse mackerel (*Trachurus trecae*) and the Cape horse mackerel (*Trachurus capensis*). The latter species, the main area of distribution of which is Namibia and South Africa, was caught only sporadically from about Tombua and southward. The Cunene horse mackerel was instead dominating throughout the shelf, to the border with Namibia. Densities were usually low but a few high concentration areas were detected off Cabo Santa Marta, Namibe, Tombua and at the entrance of Baía dos Tigres (Figure 17). As observed in the other regions, horse mackerel followed with great regularity a diel vertical migration, forming schools near the bottom during daytime and dispersing in upper water layers mixed with plankton at night. Horse mackerel appeared to be the dominant species in this region, in all depths and near the bottom as well as in the upper water layers.

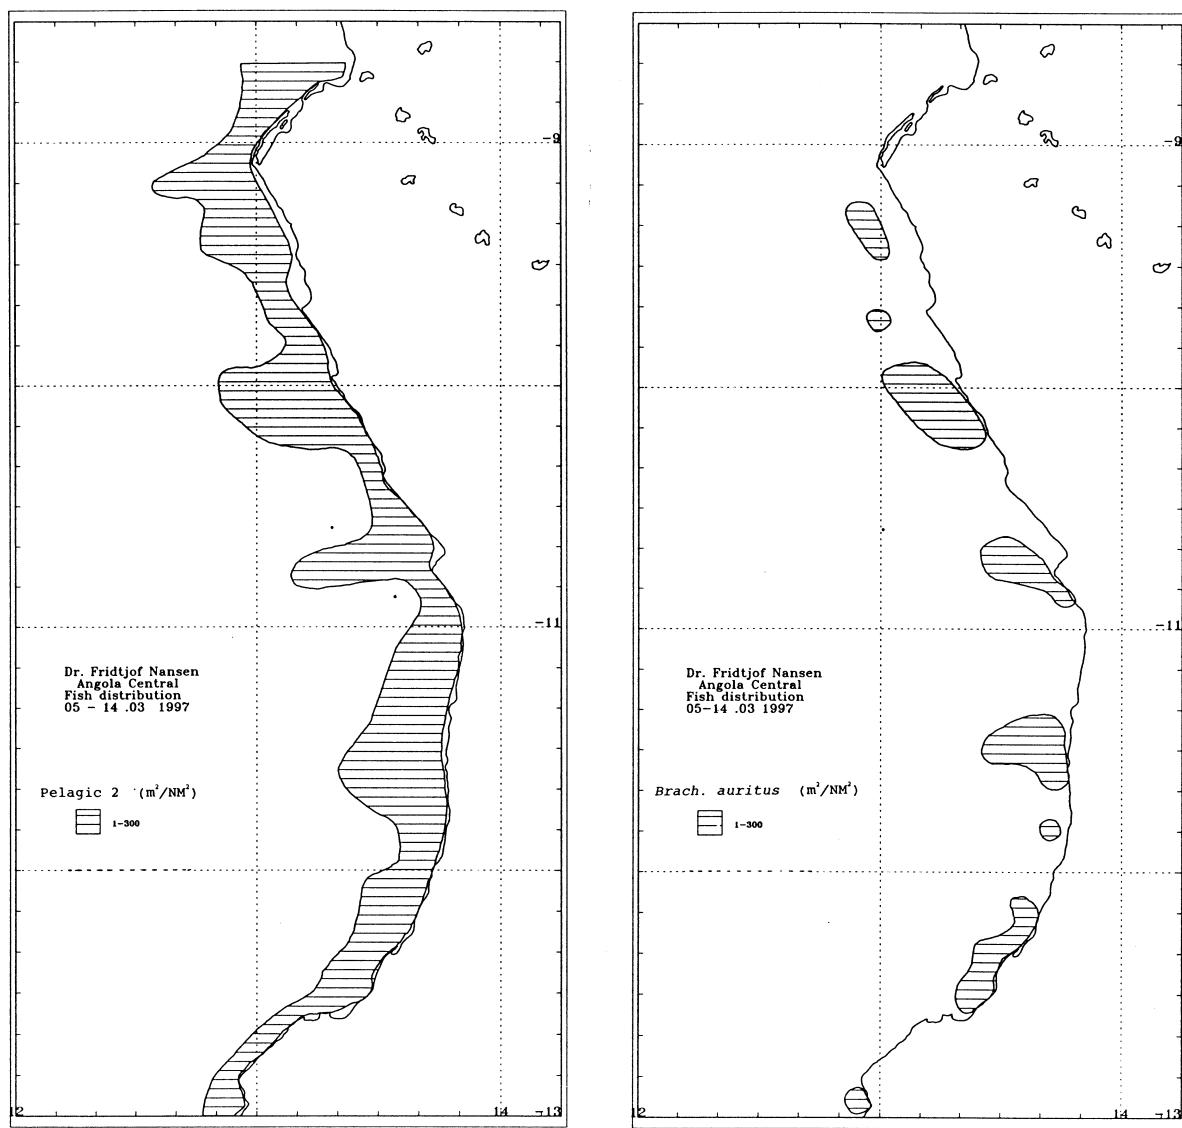

Figure 16. Distribution of other pelagic fish and bigeye grunt (*Brachydeuterus auritus*). Pta das Palmeirinhas - Benguela.

The total length frequency distributions for both species are presented in Figure 18. The figure shows the dominance, for both species, of juvenile and young fish. The biomass estimate for the region totalled 234 000 tonnes, of which more than 90% was Cunene horse mackerel.

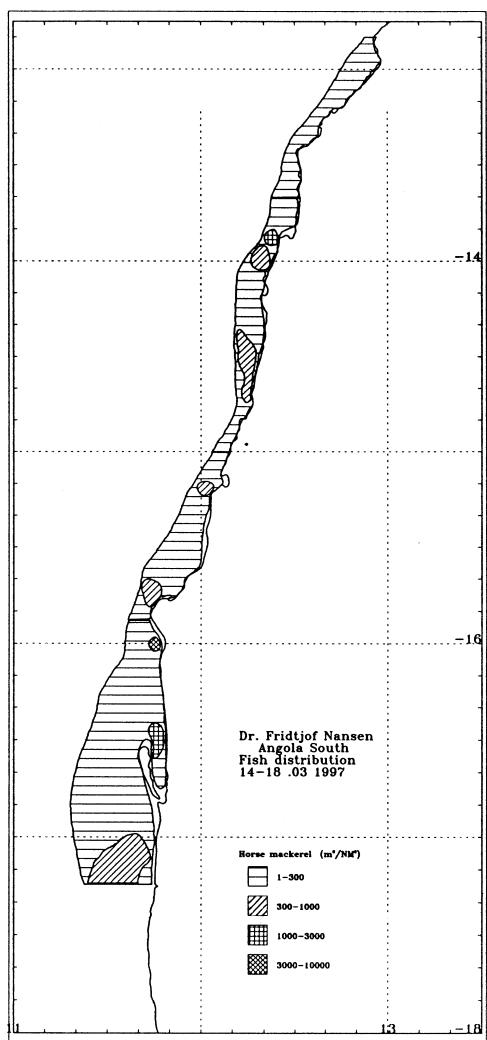

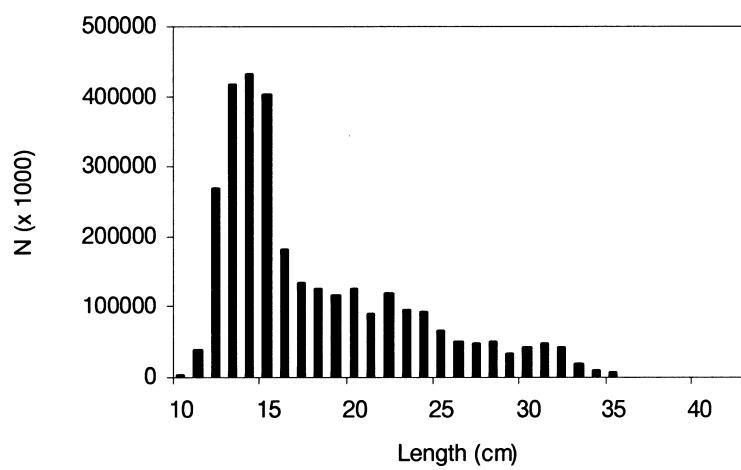

Figure 17. Distribution of *Trachurus trecae* and *Trachurus capensis*, Benguela-Cunene

a) *Trachurus trecae*

Figure 18. Total length distribution of a) *Trachurus trecae* and b) *T. capensis*. Benguela-Tombua.

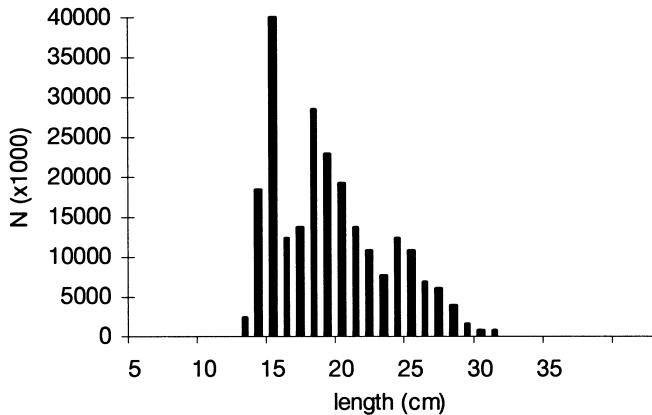

b) *Trachurus capensis*

Fig 18. Cont

4.3.2 Clupeoid species

Three young specimens of pilchard (*Sardinops sagax ocellatus*) were caught once, in shallow waters outside Baia dos Tigres and no pilchard school was detected from the eco integration system. No biomass estimate was therefore attempted.

The round herring (*Etrumeus whiteheadi*) was caught a few times, in very small amounts. Also in this case, no biomass estimate was attempted.

4.3.4 Other pelagic species

As earlier mentioned, horse mackerel totally dominated the neritic ecosystem of southern Angola (Figure 19). Horse mackerel is an important prey item for larger predators, both demersal and pelagic. *Atractoscion aequidens* and other large sciaenids fed on horse mackerel when near the bottom. Main predators of the upper water layers were *Sarda sarda*, *Trichiurus lepturus* and *Pomatomus saltatrix*. A rough estimate of pelagic species other than clupeids and carangids was attempted, by using an average length of 30 cm and a condition factor of 0.9. It resulted in about 30 000 tonnes.

CHAPTER 5 REVIEW OF SURVEY RESULTS AND AVAILABILITY FOR FISHERY

5.1 Sardinella and horse mackerel

The total biomass of sardinellas was estimated to 495 000 tonnes (Table 4). This value is higher than the last two obtained in the same season but very consistent with the value for the February/March 1994 survey. These changes in biomass probably do not reflect real biomass fluctuations but the abnormal conditions found in 1995 and 1996. Due to the abnormal high temperatures and low salinity values, pelagic species appeared to be more dispersed and thus less available to the acoustic estimation. During the present survey, the climatic conditions seemed to be cooler than normal, probably indicating an early onset of the autumn season. More than 50% of the biomass was in fact located in the northern region, which is a situation typical of the colder season.

Table 4 Biomass estimates of sardinellas by regions and surveys
(1 000 tonnes)

† surveyed from Congo River to Pta das Palmerinhas

The present estimate of horse mackerel (about 437 000 tonnes, Table 5) shows that the stock is maintaining the high levels recorded in later years. The relatively higher presence of young fish is indicative of good recruitment. The smaller amount of older fish, however, indicates a reduction of their absolute abundance as compared to earlier years.

Annex II. Length distributions of main species

Annex III Instruments and fishing gear used

The Simrad EK-500/38kHz scientific sounder was used during the survey for fish abundance estimation. The Bergen Echo Integrator system (BEI) was used to scrutinize the acoustic records from the 38kHz echo sounder, and to allocate integrator values to fish species. The details of the settings of the 38kHz echo sounder where as follows:

Fishing gear

The vessel has two different sized "Åkrahamn" pelagic trawls and one "Gisund super bottom trawl". All the above trawls were used during this survey.

The bottom trawl has a headline of 31 m, footrope 47 m and 20 mm meshsize in the codend with an innernett of 10 mm meshsize. The estimated opening is 6 m (observed 5.7) and distance between wings during towing about 18 m. The sweeps are 40 m long. The trawl is equiped with a 12" rubber bobbins gear. The doors are of 'Thyborøn' combi type, 7.81 m², 1670 kg, their distance while trawling about 46 m in average.

Both pelagic trawls have double lining at the codend, with meshes of abut 20 mm.

The SCANMAR system was used on all trawl hauls. This equipment consists of sensors, a hydrophone, a receiver, a display unit and a battery charger. Communication between sensors and ship is based on acoustic transmission. The doors are fitted with sensors to provide information on their distance and a height sensor is fitted to the bottom trawl to measure the trawl opening and provide information on clearance and bottom contact..

The pelagic trawl is equipped with a trawleye that provides information on the trawl opening and the distance of the footrope to the bottom.

Annex IV Estimation of age and growth, *Sardinella maderensis*

by Inge Fossen

Studies on length and growth of tropical species is usually rather difficult because of the lack of clear marks on the hard structures. Daily growth rings can be determined, but this is a rather tedious and time consuming method, that can be implemented only with great difficulty.

Sardinella maderensis is found off West Africa from Mauritania to Angola. Maximum abundance is in the areas with seasonal upwelling, i.e. off Senegal, Ivory Coast - Ghana and off Gabon to Central Angola. The southern stock ranges from Cape Lopez (Gabon) to Benguela (Angola).

Earlier growth studies of *S. maderensis* are available for Senegal (Samb, 1988) and Congo (Gheno and Leguen, as cited by Samb, 1988), but no study of this type is available for Angola. For this reason, an attempt was made in the course of this survey to identify suitable methods for determination of age at length and of growth parameters for this species. Because of clear seasonality in Angolan marine waters, with surface temperatures falling from 28°C to about 20 °C, presence of clear marks on hard body structures was expected.

1) Modal Progression Analysis on length data

Length frequencies were obtained from the data collected through the surveys with the RV 'Dr. Fridtjof Nansen' in the period 1994 to 1997 (Table 1). The analyses were performed by geographical region, i.e. Cabinda to Luanda and Luanda to Benguela. Specimens were always measured for total length.

The program package FiSAT (Gaynilo et al, 1994) was used. Cohorts were identified using the Bhattacharya method, followed by Modal Progression Analysis and identification of growth curve. An attempt was also made to use ELEFAN and the following results were obtained (Table 2):

Figure 1 shows the growth curves obtained from the above two methods, for the two regions. MPA suggests a slower growth, with specimens reaching about 35 cm in 4 years. ELEFAN indicates a much faster growth, the fish reaching a length of more than 30 cm after two years. Table 1 shows the growth parameters and the growth performance indices for the two regions/methods. The growth performance ($\phi' = \log K + 2\log L^\infty$) was higher in the ELEFAN output, while the differences between regions were minimal. The values obtained with MPA conform with the results obtained for Senegal and Congo (Samb, 1988).

Table 2. Growth parameters for *S. maderensis*, Cabinda- Luanda and Luanda-Benguela

	L^∞	K	ϕ'

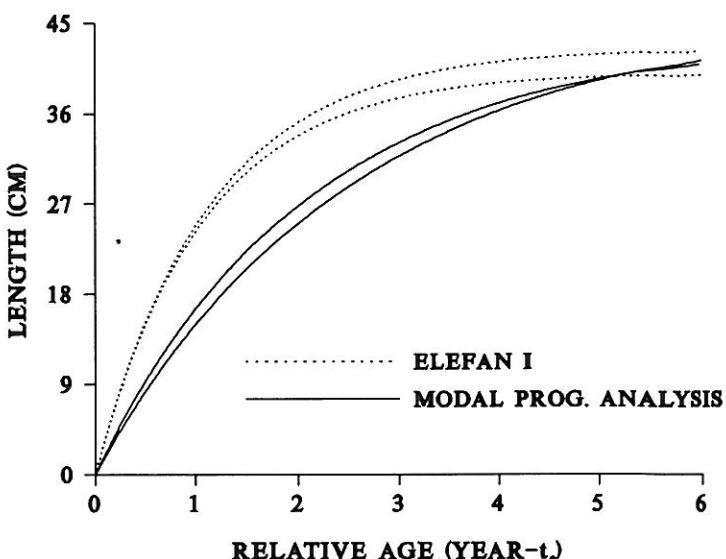

Figure 1. Growth curves for *Sardinella maderensis* for the regions Cabinda-Luanda and Luanda-Benguela

2) Age determination from otoliths

A first investigation on the applicability of this method to *S. maderensis* was based on a small sample of 50 otoliths (*Sagitta*), from specimens of 19 to 40 cm TL. Age determination was performed with a binocular and direct illumination on a black background. To facilitate the detection of growth rings, otoliths were first polished with sand paper and immersed in mineral oil.

Growth rings were clearly visible. All specimens had an outer hyaline ring indicating that they were undergoing a period of slower growth. Assuming that the distance between the hyaline rings represents one year growth, it appears that *Sardinella maderensis* reach the size of 30 cm in about 3-4 years and 40 cm in about 4-6 years. Although this first attempt is based on a small sample, they clearly indicate that age determination on otoliths is possible for this species.

3) Summary

This preliminary analysis shows that there was good agreement between length at age from otolith reading and the estimated growth function from the length frequency data obtained with MPA. Furthermore, the growth performance index obtained from this latter method appears to be consistent with earlier studies on this species from Senegal and Congo (Samb, 1988). This is reasonable, considering that the environmental conditions in these areas are quite similar to those found off northern and central Angola.

Annex V Feeding habits, *Trachurus trecae*

by

Kumbi Kilongo

The Cunene horse mackerel is an important pelagic species throughout tropical West Africa. In the regions with seasonal upwelling, like in Angola, this species reaches its maximum abundance. Besides its wide geographical distribution, little is known about its biology, particularly in the Angolan region.

In the course of the present survey 1149 stomachs of Cunene horse mackerel were collected for quantitative laboratory analysis of their contents. Inverted and regurgitated stomachs were not observed. About 61% of horse mackerel examined for stomach sampling had empty stomachs (Table 1). The study area was divided into three main regions according to the geographical distribution and abundance of horse mackerel: Cabinda - Luanda, Luanda - Lobito and Lobito - Cunene River.

The data were grouped by length, depth, and by day and night time (Tables 1 to 3). The following is only a preliminary analysis of the data collected. A more thorough analysis will be conducted at a later stage.

1. CABINDA - LUANDA

A total of 398 stomachs was collected in this area, 68.4% of which were empty. The area was characterised by a high concentration of horse mackerel of the size class between 10 - 19 cm. The highest levels of full stomachs were observed in this size class both during day and night. Degree of fulness decreased significantly between the length groups 30 to 40 cm (Figure 1 a). Euphausiid was the main prey with 68.8% of occurrence during the day time and 54.7% during the night time (Table 2). This group was dominant throughout the day and in all length groups. Amphipods and phytoplankton were less consumed in this area. The analysis of strata showed that euphausiids were consumed from 0 to 100 m of depth, with higher occurrence between 0 and 50 m during both periods (Table 3).

2. LUANDA - LOBITO

471 stomachs were collected in this area and 71.6% were empty. The highest abundance of horse mackerel was observed between the length group 10 - 19 cm. The highest percentage of full stomachs during daytime was observed in the length group ≥ 40 , but this result is not too reliable

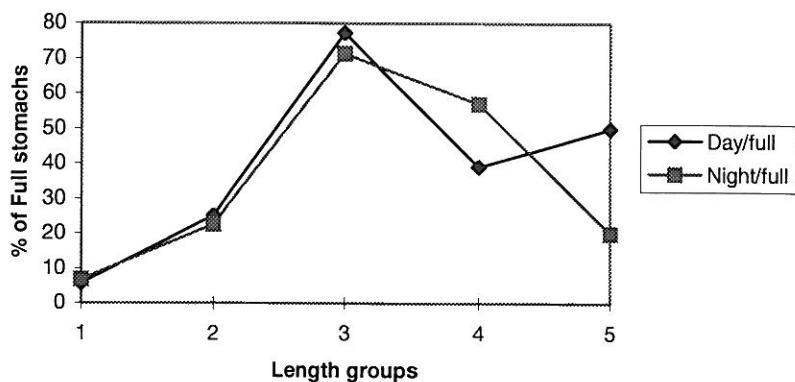

due to the small number of stomachs sampled in this size group. No stomachs were collected for the group of less than 9 cm during the day time (Figure 1 b). Euphausiids were the preferred prey in this region, with the highest frequency of occurrence throughout the length groups both during daytime as well as nighttime. Amphipods, fish larvae and foraminifera were of the less importance according to the frequency of occurrence (Table 2). Euphausiids were mainly consumed in the stratum between 0 - 50 m of depth during both periods, while fish larvae dominated the stratum \geq 100 m during daytime (Table 3). Foraminifera were found only in this area and during nighttime, between 0 and 50 m of depth.

3. LOBITO - RIO CUNENE

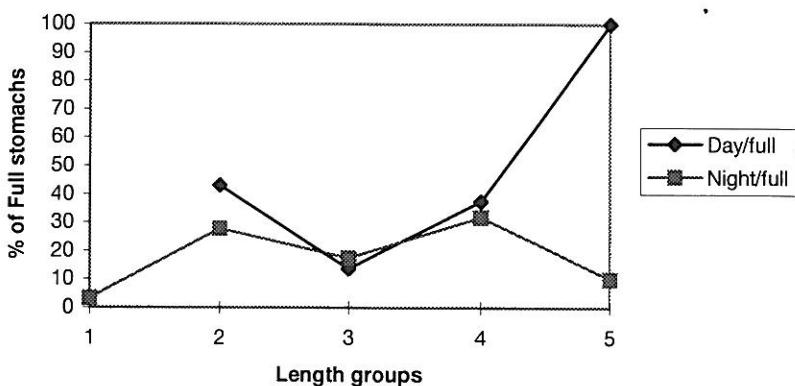

280 stomachs were collected between Lobito and Cunene River and about 53.9 % were empty. The number of full stomachs was higher between the length group 10 - 19 during the night time, and between the length group 30 - 39 during the day time (Figure 1 c). No predator of the length group \geq 40 was analysed. Copepods were the dominant prey of horse mackerel in this region, with 34.8 % of occurrence during the day time and 63 % during the night time (Table 2). Worms and mysids were only found in this region and were mostly consumed during daytime. Copepods were the main prey between 0 - 50 m during both periods, and mysids between 100 - 150 m during the day time (Table 3). Copepods were also more consumed (100 % of occurrence) between 100 and 150 m depth, during nighttime.

Figure 1: Percentage of full stomachs by length groups (cm), regions and time of the day
 (1 = ≤ 9 , 2 = 10-19, 3 = 20-29, 4 = 30-39, 5 = ≥ 40).
