CHAPTER 1 INTRODUCTION

1.1 Objectives

The objectives of the survey, previously agreed upon with the Director of the Instituto de Investigaçāo Pesqueira (IIP) and briefly discussed with the Angolan participants of the cruise are the following:

- To describe the distribution, composition and abundance of the major demersal resources, with special emphasis on deep-water shrimps (*Parapenaeus longirostris* and *Aristeus varidens*), seabreams (Sparidae), Benguela hake (*Merluccius polli*) and other species of shrimp in the by-catch, in the area from Luanda to Benguela.
- To map the general hydrographic regime by using a CTD-sonde at trawl stations all over the survey area and monitor temperature, salinity, and oxygen, along IIP standard profiles, for hydrographic studies.
- To carry out comparative fishing trials with the bottom trawls of R/V “Dr. Fridtjof Nansen” and the commercial shrimp trawler “Palmeirinhas”. To investigate the possibility of using this commercial trawler in future demersal surveys in Angola.

1.2 Participation

The scientific staff consisted of:

From IIP, Angola:

Domingos AZEVEDO, Kumbi KILONGO, Gisela RAMOS, Maria de Lourdes SARDINHA, Ana de SOUSA, Pedro TCHIPALANGA and Filipe VIANDA.

From IMR, Norway:

Oddgeir ALVHEIM, Guillermo BURGOS, Magnar MJANGER, Erik OLSEN (7/05-13/5), and Jan Arne VÅGENES.

1.3 Narrative

The vessel left Luanda in the afternoon of May 7 and steamed westwards together with the shrimp trawler 'Palmeirinhas'. In the evening, the vessels started trawling in parallel course to practice the routine and to test the SCANMAR trawl opening sensors on the gear of 'Palmeirinhas'. During this first trawl haul, both trawl warps of 'Dr. F. Nansen' snapped. The whole gear was recovered but the vessel was not ready to trawl until the evening of May 8. From then onwards, the sampling programme began with course tracks approximately 20-25 NM apart, covering the inner, middle and outer shelf and the slope to about 750 m depth. Semi-random bottom trawl hauls were carried out on the shelf during daytime and on the slope deeper than 400 m also during dark hours. The gear inter-calibration with the 'Palmeirinhas' was done in locations corresponding to trawl stations of the standard bottom trawl survey. The joint activity with 'Palmeirinhas' was adapted to the working possibilities of the commercial trawler, that is, 12 working hours a day. The comparison of bottom gear performance between 'Palmeirinhas' and 'Dr. Fridtjof Nansen' was conducted between the evening of May 8 and the morning of May 13. As part of the routine survey of demersal resources, CTD stations were taken at most of the bottom trawl stations. Besides, additional CTD recordings were collected in the standard IIP hydrographic sections of Pta. das Palmeirinhas, Pta. do Morro and Lobito. The studied area delimited by Luanda and Benguela and the isobath of 20 and 800 m was covered from May 8 to May 19. While sailing southwards, the hydrographic section in front of Baia dos Tigres was completed on May 20. The cruise finished on May 22 when 'Dr. Fridtjof Nansen' called in Walvis Bay, Namibia.

1.4 Survey effort

Table 1 presents the number of CTD and fishing stations and the distance surveyed. Figure 1 shows the general cruise track and the locations of bottom trawl and hydrographic stations.

Table 1. Number of hydrographic stations (CTD), bottom trawl stations (BT), successful swept-area hauls per depth strata and distance surveyed. Luanda-Benguela

			0-200m	200-400m	400-800m	
Luanda - Benguela	86	72	38	14	19	1400
Baia dos Tigres	7	0	0	0	0	

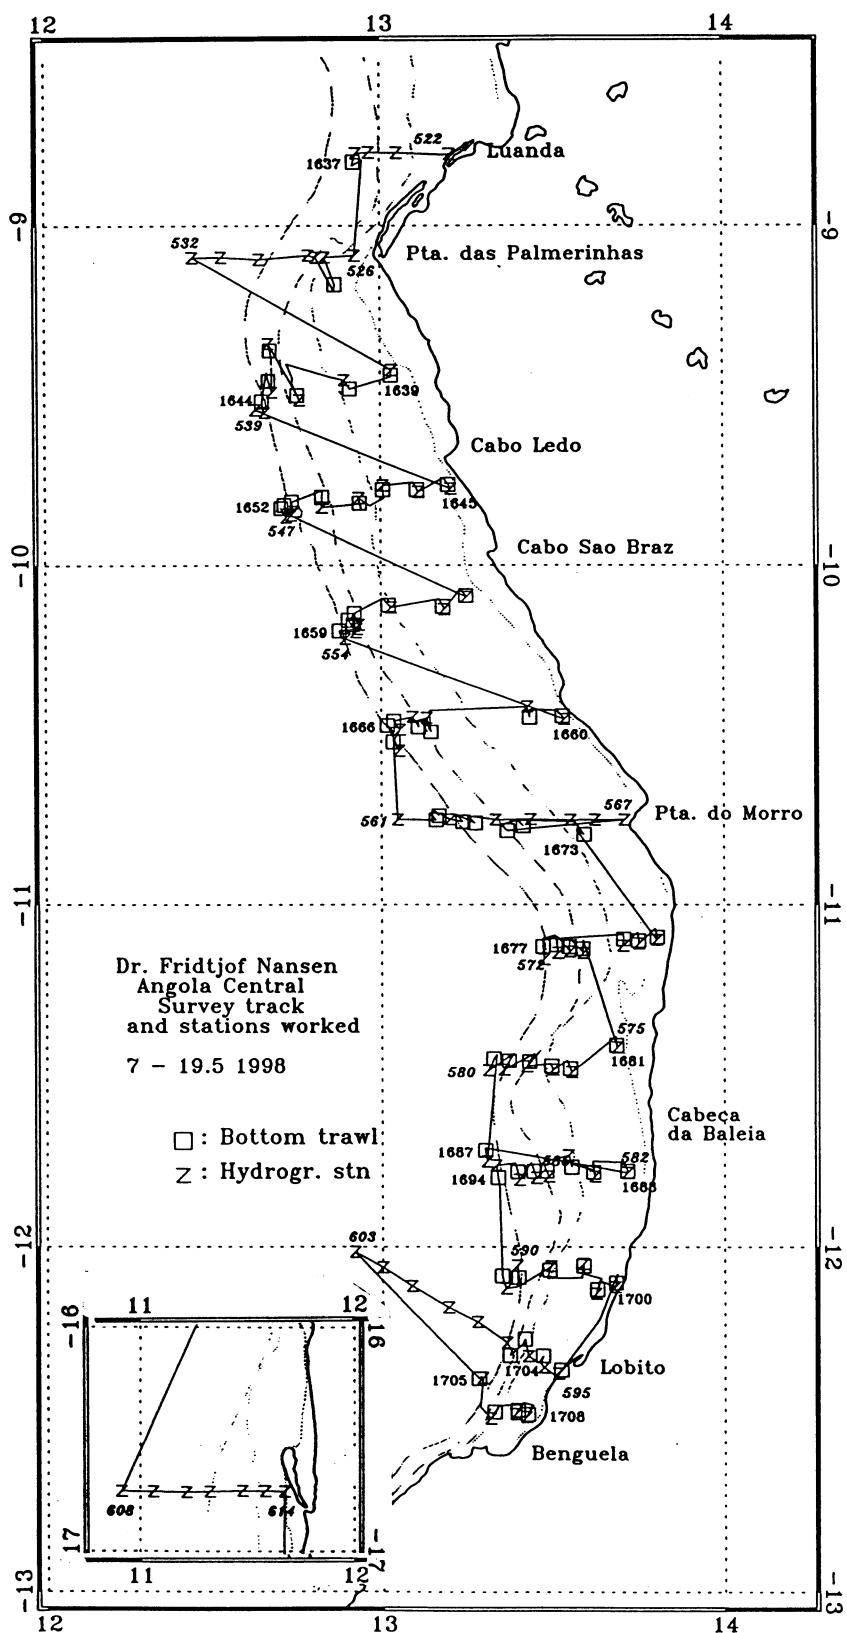

Figure 1. Course track with fishing and hydrographic stations. Luanda-Benguela

CHAPTER 2 METHODS

2.1 Hydrographic sampling

A Seabird 911 + CTD probe was used to obtain vertical profiles of temperature, salinity and oxygen. Real time plotting and logging was done using the Seabird Seasave software installed on a PC. The profiles were in general taken down to a few meters above the bottom. In deep stations however, data logging was interrupted at 700m. At each station two Niskin bottles were triggered for water samples, one near the surface and one near the bottom. In order to calibrate the oxygen and salinity sensors, water samples were analysed for dissolved oxygen using the Winkler method and salinity using a Guildline Portasal salinometer mod. 8410.

A total of 61 samples were accepted for oxygen calibration. A linear regression of the Winkler determinations on the CTD values gave the following results:

$$O_2 = O_{2\text{ CTD}} * 1,078 + 0.087$$

The standard deviation of the difference between both measurements was 0.187

A total of 25 salinity samples were accepted for calibration. The average difference between laboratory readings and CTD values was -0.026 with a standard deviation of 0.0142.

The results presented in this preliminary report have not been adjusted according to the last calibration values. Corrected values will be presented in the final version of this report.

No current profiles with ADCP were recorded during this cruise.

Meteorological observations including wind direction and speed, air temperature, global radiation and sea surface temperature (SST) were automatically logged every nautical mile using an Anderaa meteorological station.

2.2 Fish sampling

Catches were sampled for species composition by weight and numbers. Samples of deep-water rose shrimp (*Parapenaeus longirostris*) and striped red shrimp (*Aristeus varidens*) were also separated by sex. Length measurements were taken as follows: total body length (cm) of fish was measured to the nearest 1 cm below and carapace length (mm) of shrimp was measured to the nearest 1 mm below. Biological samples, i.e. total body length, total body weight, sex and maturity stages, were taken for *P. longirostris* and *A. varidens*. The records of fishing stations are presented in Annex I. Pooled length frequency distributions of selected species by area are shown in Annex II; individual frequency distributions were pooled together using the catch in the corresponding trawl haul as weighing factor.

Table 2 shows the areas used in the swept-area biomass estimates. These strata were used to make comparable calculations with previous years. More complete and updated values of depth strata areas are presented in Table 3.

Table 2. Areas used in the swept-area biomass estimates (nm ²)		
Depth stratum (m)	Cabinda-Luanda	Luanda-Benguela
0-50	3 023	1 850
50-100	2 693	1 730
100-200	2 085	1 252
200-300	755	500
300-400	660	350
400-500	540	445
500-600	880	450
600-800	1500	(900)

A stratified semi-random design was used, with depth and degree latitude as stratifying variables. Planned allocation of trawl stations began with a proportional sampling effort to the stratum size. This original design was slightly changed to increase the number of trawl stations in the main distributional area of deep-water shrimps. The depth range from 20m to 750m depth was sampled between south of Luanda to Benguela bay. Biomass estimates by species were obtained by summing up the estimates calculated for each depth stratum.

Table 3. Areas of each stratum defined on depth and degree latitude.

Depth stratum (m)	Congo River-Luanda degrees latitude			Luanda-Benguela degrees latitude				Total
	6-7° S	7-8° S	8 -9° S	9-10° S	10-11° S	11-12° S	12-13° S	
20-50	595	520	264	320	353	310	85	2447
50-100	827	685	457	393	607	344	242	3556
100-200	744	706	490	425	587	319	108	3378
200-300	262	145	194	160	116	103	28	1008
300-400	235	154	161	105	116	123	28	922
400-500	184	142	111	102	101	86	54	781
500-600	161	148	100	102	104	92	48	754
600-700	181	151	76	73	66	72	57	676
700-800	333	272	97	87	101	109	60	1059
Total	3523	2921	1950	1767	2151	1558	712	14582

The bottom trawl used during this survey has a headline height of 5-6 m and a distance between wings during towing of about 21 m. The footrope was equipped with a tickler chain to improve the catchability of deep-water shrimp in samples taken deeper than 300m. During trawling a 9.5 m long rope (strapping) was fastened between the wires 130 m in front of the doors giving a constant distance between the doors of 49-50 m. All trawl hauls were monitored by SCANMAR trawl sensors and the actual time the trawl was fishing on the bottom was determined with improved accuracy. A more detailed description of the fishing gear is given in Annex IV. For conversion of catch rates to fish densities, the area between the wings is assumed to be the effective fishing area. The catchability coefficient q was assumed equal to 1. The length of a haul, recorded as distance over the bottom, was measured by the GPS.

Acoustic recordings were stored in paper echograms and in the BEI echo-integration system. It was not possible during the cruise to scrutinise the echograms to allocate echo-integrator values between the different species. Raw data were stored for future analysis.

CHAPTER 3 OCEANOGRAPHIC CONDITIONS

3.1 Surface distribution

The horizontal distributions of surface temperature and surface salinity (5m depth) are shown in Figs. 2 a -b, respectively. Sea surface temperatures (SST) between 24 and 28°C were found in the Angolan central region. Compare with last year survey, temperatures were 2-3 degrees higher during this cruise. In general, SST increased monotonically with distance from the coast along the whole coast line. Minimum temperatures were recorded south of Pta. do Morro and between Cabeça da Baleia and Lobito. Sea surface salinity showed a very dynamic distribution in the range 33.2 - 36.0 ‰. A nucleus of water masses of relatively low salinity were found off Pta. das Palmerinhas, probably originated from river discharge. The salinity distribution also suggested the contribution of coastal run-off being transported southwards by a coastal current.

3.2 Vertical sections

In Figs. 3a-d, the vertical distribution of temperature, salinity and oxygen are shown for the 4 sections worked during the survey (3 inside the studied area, and 1 outside off Baia dos Tigres). A thermocline was found between 10 and 30 m depth. Low salinity surface water was evident in the sections off Pta. das Palmerinhas and Pta. do Morro. A relative flat structure was observed in most sections, but there were signs of coastal upwelled water off Lobito. In the additional hydrographic section made on our way to Walvis Bay, off Baia dos Tigres, a clear upwelling process with isolines bending upwards in the direction of the coast in the three fields analysed could be seen.

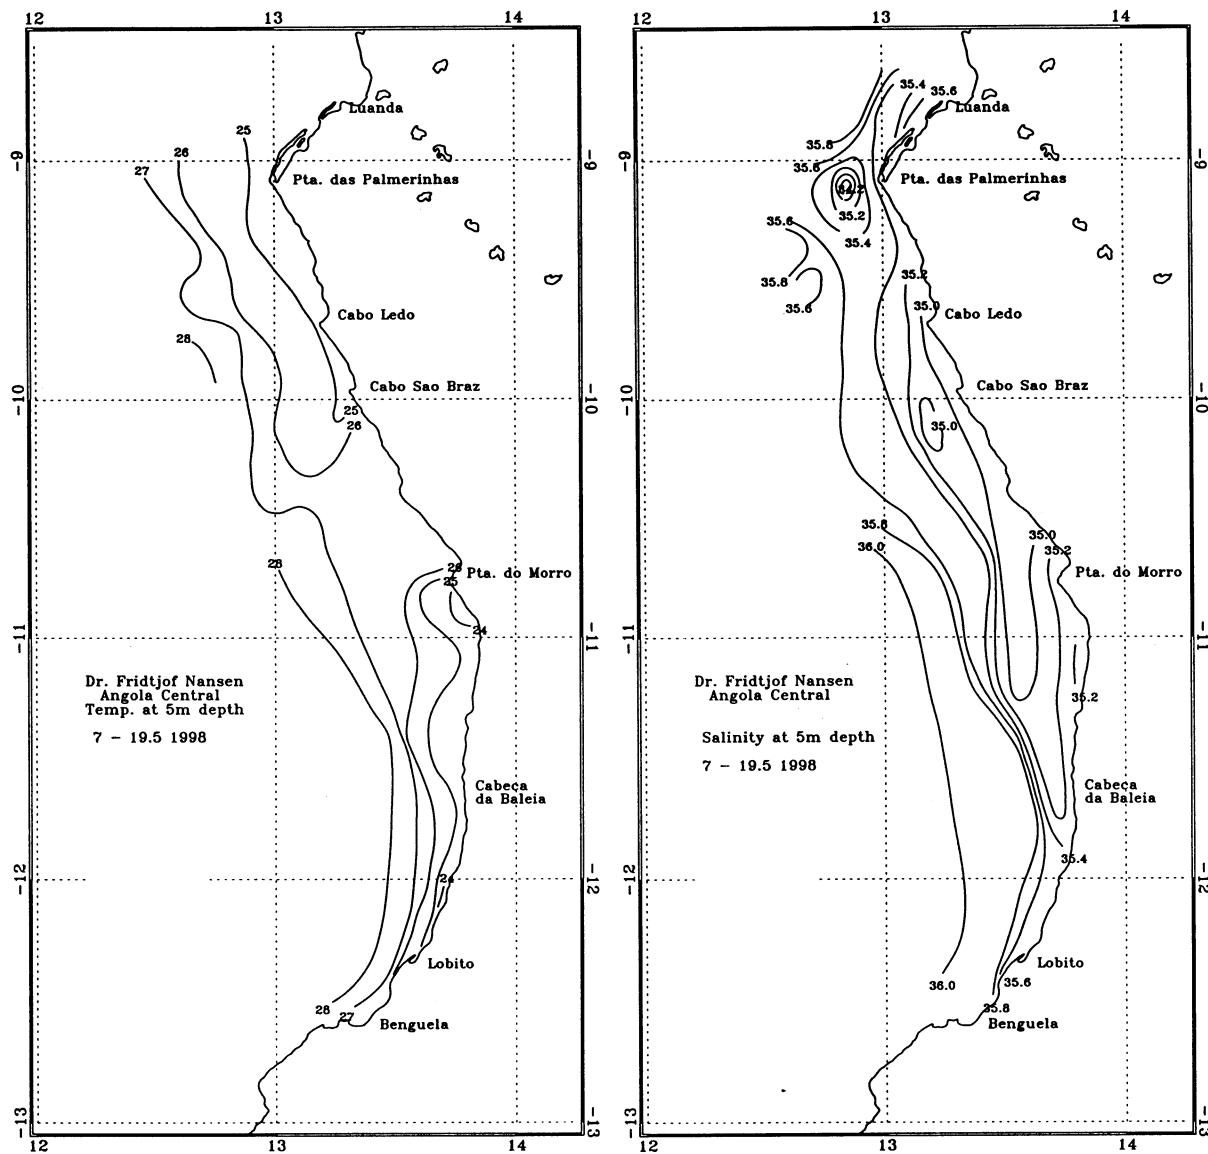

Figure 2. Horizontal distribution of a) surface temperature (5m depth) and b) surface salinity. Luanda-Benguela.

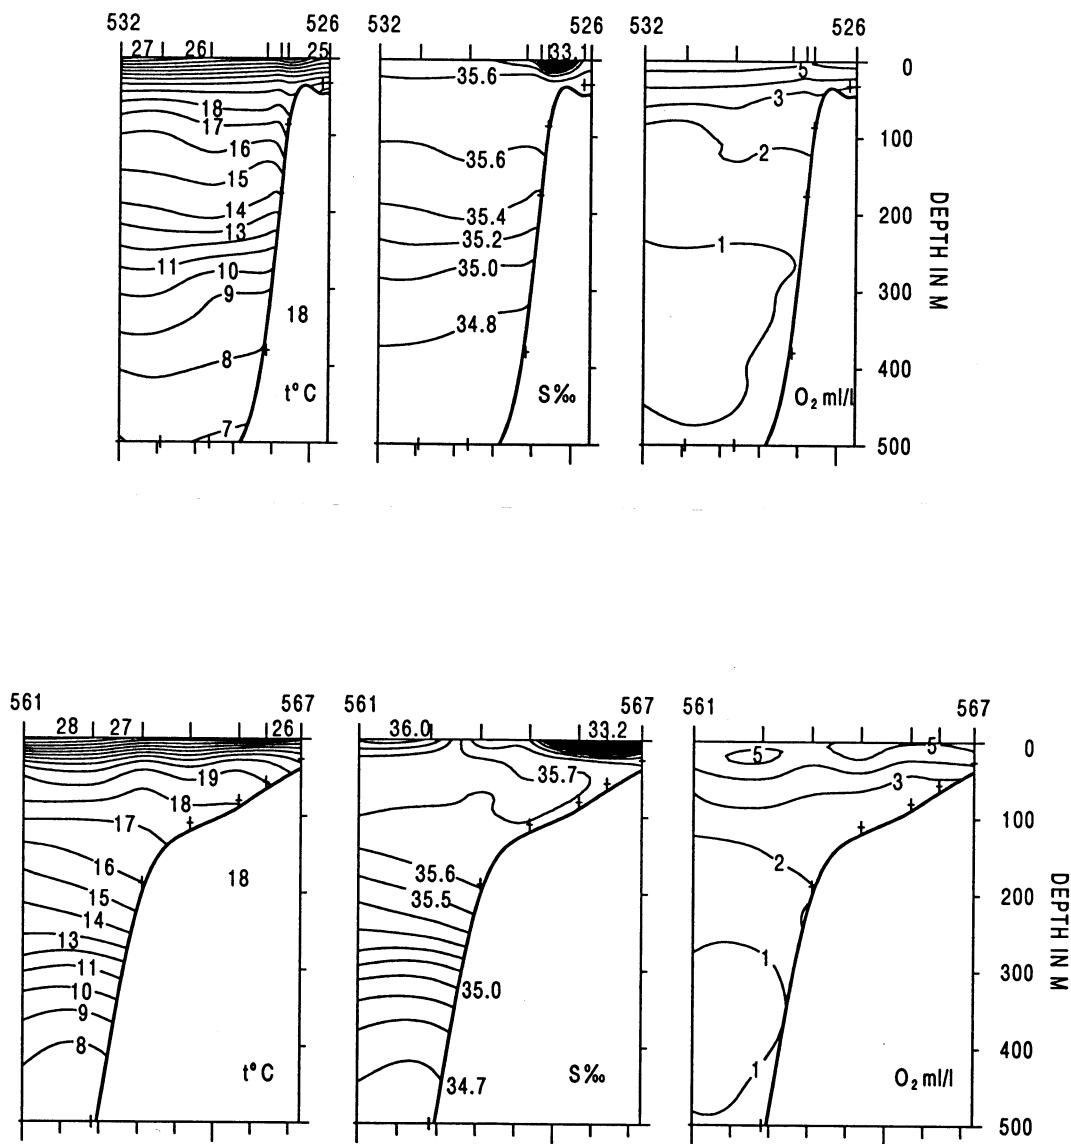

Figure 3. Vertical sections of a) temperature, b) salinity and c) oxygen.

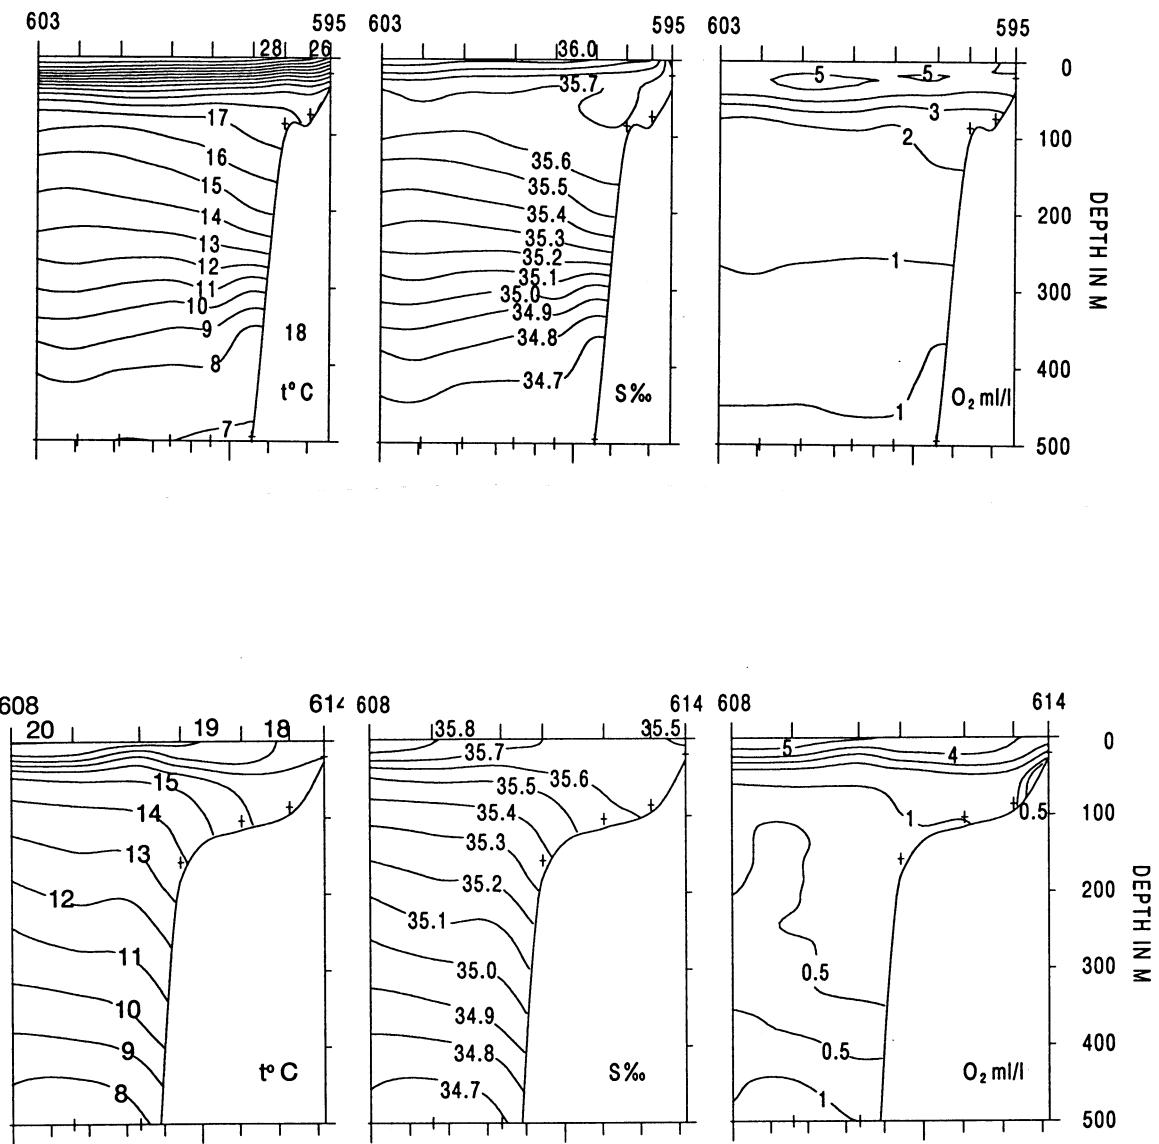

Figure 3 (cont) Vertical sections of a) temperature, b) salinity and c) oxygen.

CHAPTER 4 CATCH RATES, DISTRIBUTION, COMPOSITION AND BIOMASS ESTIMATES OF DEMERSAL FISH (SHELF)

The catch species composition on the Angolan shelf between Luanda and Benguela was studied in two different depth strata: 20-70 m depth (inner shelf) and 71-200 m depth (outer shelf). The results for the slope area are presented in Chapter 5. The locations of the trawl stations are shown in Fig. 1. Records of fishing stations and catches are presented in Annex I, and pooled length distributions (weighted by the catch) of main species are shown in Annex II.

In the swept-area biomass estimates for the shelf down to 200 m, the depth strata 0-50m, 50-100m and 100-200 m were used. Mean densities by depth strata of the main species, the incidence and the catch distributions are shown in Annex III.

4.1 Luanda-Benguela shelf

A total of 38 successful swept-area trawl stations were accomplished on the shelf area. Table 4 shows the catch rates by main species groups for the inner (20-70 m) and the outer shelf (71-200 m). The group "Demersal" comprises the commercially important families Sciaenidae, Haemulidae (=Pomadasytidae), Serranidae, Sparidae and Lutjanidae, while the group "Pelagic" includes the families Engraulidae, Clupeidae, Carangidae, Scombridae, Sphyraenidae and the benthopelagic family Trichiuridae. In the inner shelf, the average catch rate of both 'Demersal' and 'Pelagic' were slightly lower than last year estimates, but still they dominated the average catch rate with a relative contribution of 48% and 44%, respectively. The average catch rate of both sharks and shrimps were relatively small but, compare with last year's estimates, the sharks were in similar level while the shrimps increased dramatically. The average catch rate of both Cephalopods and non commercial fish was found about half of last year's estimates. In the outer shelf, the 'Demersal' group was dominating with a catch rate more than twice of that of last year; however, this increase is the result of one trawl haul that had to be interrupted because of sea bottom conditions and that after 8 minutes brought a catch of 1.6 tonnes of mainly big-eye dentex. Excluding that trawl, the average catch rate of 'Demersal' was 312 kg/hour which is close to last year value. Except for 'Sharks' that had a catch rate similar to last year's, the rest of the groups showed a significant decline.

Table 4. Catch rates (kg/hour) by main groups in swept area bottom trawl hauls on the shelf

Catch rates of the most important pelagic fish families are presented in Table 5. Except for the increase on the catch rate of hairtails (Trichiuridae) in the inner shelf, all the families considered showed an important decrease in the catch rate when they are compared with last year's estimation. Carangids showed the same average catch rate in the inner and outer shelf, and represented the most important pelagic family in the outer shelf. Cunene Horse mackerel (*Trachurus trecae*) was the most important species, followed by African lookdown (*Selene dorsalis*) and in shallower waters by Atlantic bumper (*Chloroscombrus chrysurus*). Clupeids followed in importance in the inner shelf represented by *Ilisha africana* and *Sardinella maderensis*, both species confined to shallow waters. Barracudas, mainly *Sphyraena guachancho*, were caught only on the inner shelf with a mean catch rate about seven times

lower than the one obtained last year. Small tuna of the family Scombridae were caught incidentally both in the inner and outer shelf.

Table 5. Catch rates (kg/hour) of main pelagic families on the shelf obtained with bottom trawl hauls.

Table 6 presents the catch rates of the most important demersal species grouped into families. The family Pomadasidae (grunts) clearly dominated on the inner shelf. The second most important group was seabreams followed by croakers and then groupers. During last year cruise, croakers and then seabreams were the dominant families in the inner shelf while grunts came in third place. The mean catch rate of grunts estimated during this cruise was almost 6 times

higher than that of last year, seabreams had a comparable level while the catch rate of croakers was half of that of last year. Seabreams were the dominating family on the outer shelf with a mean catch rate almost three times higher than last year estimate. The most abundant species were *Dentex macrophthalmus* and *Pagellus bellottii*, followed by *D. angolensis* and *D. barnardi*. Croakers were the second family in importance in the outer shelf with a catch rate twice as high as last year estimate. Like on the inner shelf, the groupers were rare, occurring only in one station. The snappers (*Lutjanus* spp.) were absent on the inner and on the outer shelves.

Table 6. Catch rates (kg/hour) of valuable demersal species grouped by families; bottom trawl hauls on the shelf. LUANDA-BENGUELA

Figure 4 shows the distribution of the seabreams in the region between Luanda and Benguela.

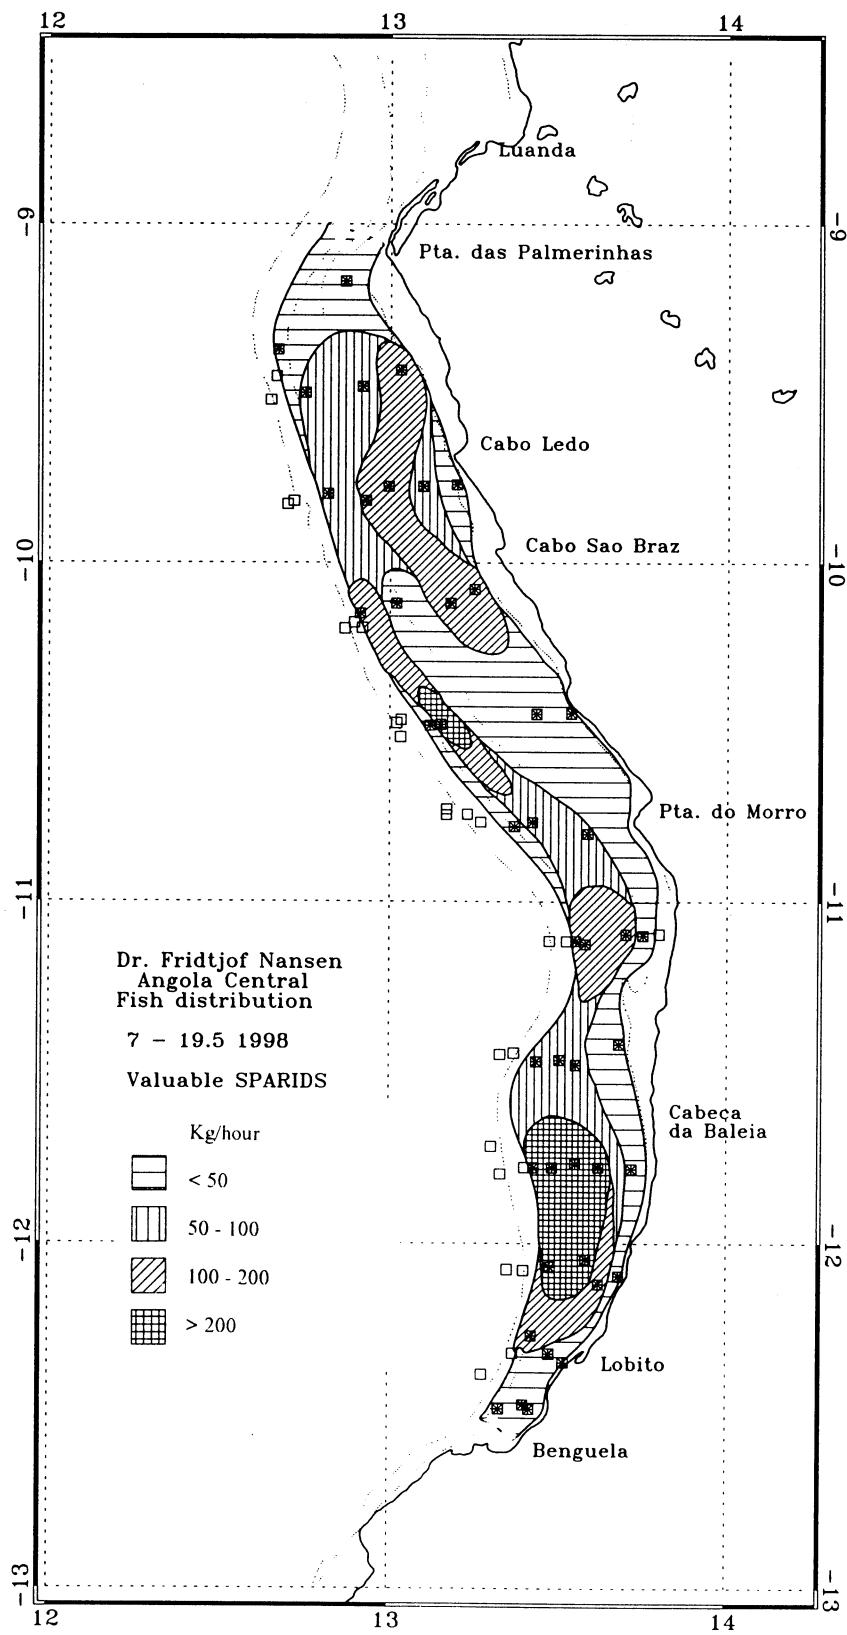

Figure 4. Distribution of seabreams (family Sparidae). Luanda-Benguela

Seabreams were distributed from the inner shelf to about 300 m depth on the slope, with the highest abundance on the outer shelf and upper slope. Four main areas of concentration (>200kg/hr) can be observed for this group. Same as last year, the best catches were taken between Cabeça da Baleia and Lobito.

In Annex III A, swept-area estimates of mean densities based on 38 random bottom trawl hauls are presented for demersal species on the shelf. *Trichiurus lepturus*, *Brachydeuterus auritus* and *Pomadasys juvelini* were the three more abundant species in the 20-50 m zone, followed by *Galeoides decadactylus*. *B. auritus*, *Atractoscion aequidens* and *P. bellottii* were the three more abundant species between 50 and 100 m. The range 100-200m was clearly dominated by *D. macrourus* followed by *D. angolensis* and *S. microlepis*. It is quite remarkable that relatively low densities of *S. microlepis* were found during this cruise while during last year cruise this was the most abundant species between 50-200m depth.

The total biomass of valuable demersal groups is presented in Table 6.

4.2 Review of results

The most important feature of this year's biomass estimates was the pronounced increase in of Seabreams and grunts as compared with last year. At the same time, with the exception of hairtails, most pelagic and semi-pelagic species showed a strong decrease. A more careful analysis should be done, specially to clarify the reasons for these abrupt changes in the estimates of seabreams and grunts. The results should be considered as very preliminary until a more in depth study is made of the present data.

Table 7 summarises the biomass estimates for valuable demersal fish in the period 85 - 98.

CHAPTER 5 CATCH RATES, DISTRIBUTION, COMPOSITION AND BIOMASS ESTIMATES OF DEEP-WATER SHRIMP AND HAKE (SLOPE)

The slope off Luanda-Benguela was covered with swept-area hauls with the following distribution: 200-400 m: 14 hauls and 400-800 m: 19 hauls. The results from the swept-area analysis by depth intervals are presented in Annex III C and D.

**Table 8. Catch rates (kg/hour) by main groups in swept area bottom trawl hauls on the slope.

Table 8 shows the composition of the catches by major groups on the slope. The groups included under 'Demersal' are families of commercial interest (including hake) that represented about 26% of the total catch.. The category 'Shrimps' included all shrimp species caught and made, in average, 17% of the total catch. It is worth noticing that 50% of the catch was conformed by groups not considered in the analysis i.e. 'Other'. Except for the 'Pelagic' group, the catch rates of all the rest categories were lower than last year's ones.

5.1 Deep water shrimp

Table 9 shows the catch rates of important shrimps and bycatch species on the slope off Luanda-Benguela. Deep-water shrimps were caught at all stations, and like in previous investigations spider shrimp (*Nematocarcinus africanus*) had the highest catch rate, a little higher than those obtained in 1997. The overall mean catch of *P. longirostris* was 10.57 kg/h, which is slightly lower than what was obtained in 1997 while the catch rate of *A. varidens* (12.84 kg/h) was much higher than last year. Hake was the most important species of fish in the slope with a mean catch of 150.58 kg/h.

Table 9. Catch rates (kg/hour) of main shrimp and bycatch species in swept area bottom trawl hauls on the slope. LUANDA-BENGUELA.

Figs. 5 and 6 show the distribution of *P. longirostris* and *A. varidens* respectively. The highest catch rates of *P. longirostris* were obtained between Ponta das Palmeirinhas and Cabo Ledo, south of Cabo São Bras and between Ponta do Morro and Cabeça da Baleia. *A. varidens* had a much more scattered distribution, with a small area with catch rates between 10 -25 kg/h. off Cabo Ledo and a area with a very high concentration (> 25kg/h) between Lobito and Benguela.

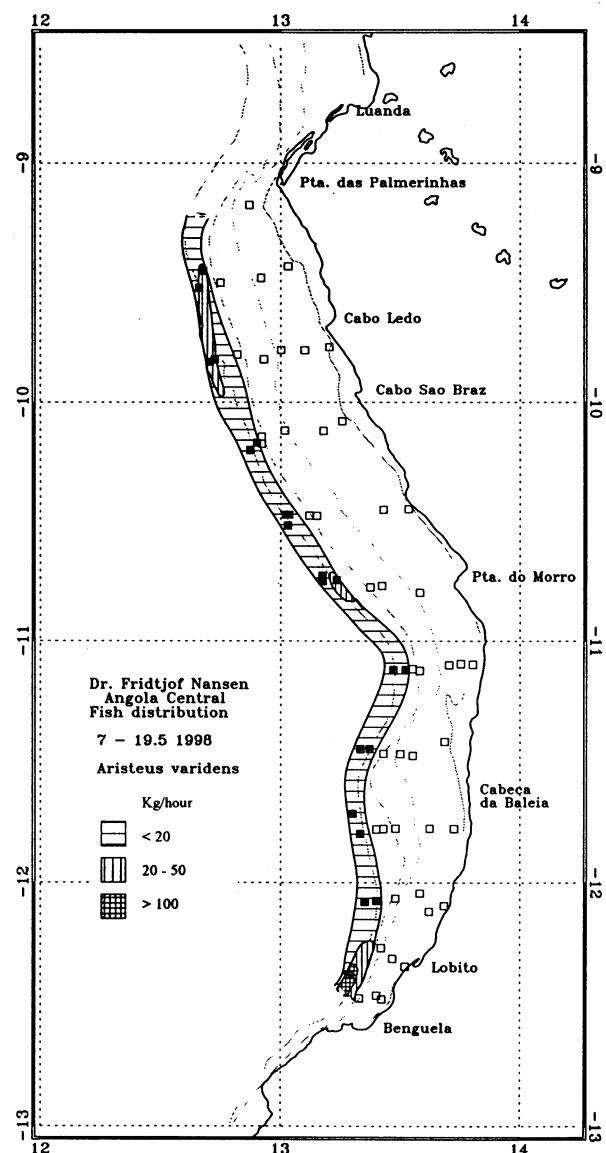

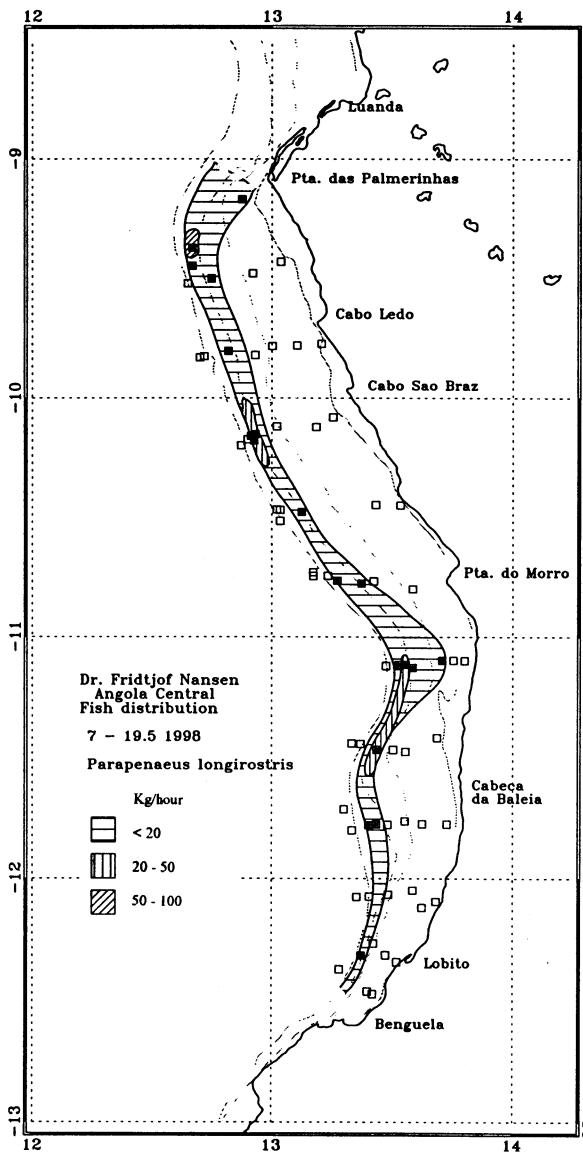

Figure 5. Distribution of rose shrimp *Parapenaeus longirostris*). Luanda-Benguela.

Figure 6. Distribution of striped red shrimp (*Aristeus varidens*). Luanda-Benguela

Mean catch rates of *Parapenaeus longirostris* (rose shrimp) by depth are shown in table 10. In the Luanda - Benguela region, the highest mean catch rate was recorded between 200-300 m , following the same trend found in 1997.

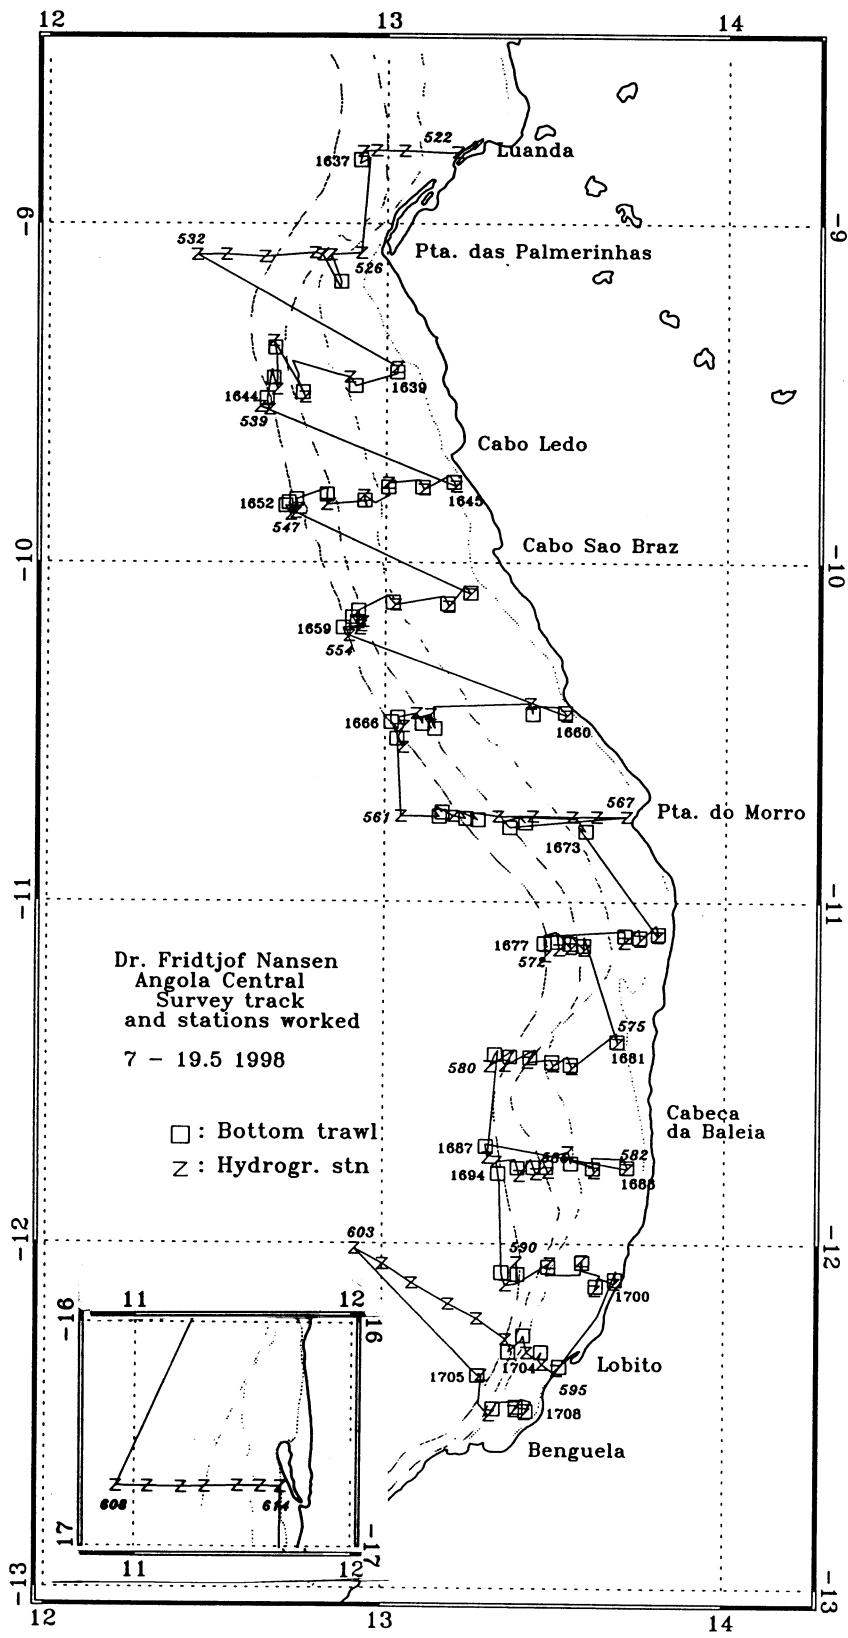

Table 10. Rose shrimp. Mean catch rates (kg/hour) by region, depth range and year of investigation.

Mean catch rates of *A. varidens* (striped red shrimp) are presented in Table 11. In the Luanda-Benguela region, the overall mean catch rate estimate gave the highest value in the time series (22kg/h). The highest mean catch rate was observed within stratum 600-800 m which was not covered in some of the previous surveys including the last.

Biomass estimates of commercially important shrimps are presented in Table 18. In the Angolan central region the biomass estimate of *A. varidens* increased considerable and is more than three times compared to last year and the highest in the time series. The biomass of *P. longirostris* was less than half compared to last year.

5.2 Benguela hake

The mean catch rates of Benguela hake (*Merluccius polli*) in the two regions by depth zone are shown in Table 13. The mean catch rate estimated in the present survey was lower than the one obtained in 1997, but is among the highest in the time series. Like in previous surveys the best catch rates were obtained between 300 and 400 m depth.

Biomass estimates of hake are presented in Table 14. The biomass estimate represent a decrease of around 25 % in the Luanda-Benguela region compared to the results of last year survey.

* no survey

Fig. 7 shows the distribution of hake in the Luanda-Benguela area. The highest catch rates > 200 kg/ were observed in a large area between South of São Bras and 12 S (South of Cabeca da baleia), and a small area between Ponta das Palmeirinhas and Cabo ledo.

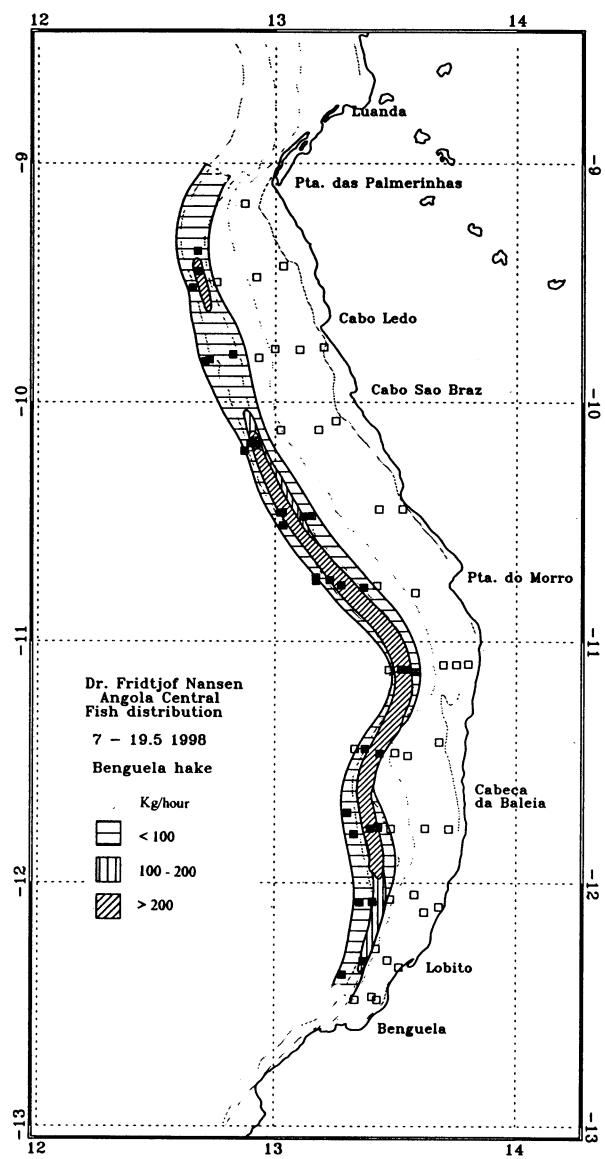

Figure 7. Distribution of Benguela hake (*Merluccius polli*). Luanda-Benguela.

Annex I Records of fishing stations

Annex IV Instruments and fishing gear used

The Simrad EK-500/38kHz scientific sounder was used during the survey for fish abundance estimation. The Bergen Echo Integrator system (BEI) was used to scrutinize the acoustic records from the 38kHz echo sounder, and to allocate integrator values to fish species.

The details of the settings of the 38kHz echo sounder where as follows:

Tranceiver-1 menu (38 kHz lowering keel)

Transducer depth	5.00 m
Absorbtion coeff.	10 dB/km
Pulse length	medium (1ms)
Bandwidth	wide
Max power	2000 Watt
2-way beam angle	-21.0 dB
SV transducer gain	27.7 dB
TS transducer gain	27.8 dB
Angle sensitivity	21.9
3 dB beamwidth	6.8 dg
Alongship offset	0.00 "
Athwardship offset	0.04 "

Display menu

Echogram	1 (38 kHz)

Range start	0
Bottom range	12 m
Bottom range start	10 m
Sv colour min	-67 dB
TVG	20 log R

Bottom detection menu Minimum level -45 dB

Fishing gear

The vessel has two different sized "Åkrahamn" pelagic trawls and one "Gisund super bottom trawl". During the present survey only the bottom trawl was used.

The bottom trawl has a headline of 31 m, footrope 47 m and 20 mm meshsize in the codend with an innernett of 10 mm meshsize. The estimated opening is 6 m (observed 5.7) and distance between wings during towing about 18 m. The sweeps are 40 m long. The trawl is equipped with a 12" rubber bobbins gear. The doors are of 'Thyborøn' combi type, 7.81 m², 1670 kg, their distance while trawling about 46 m in average. This distance is kept constant at all depths by the use of a 9.5 m strap between the wires at 130 m distance from the doors (applied at depths greater than 60 m). A tickler chain (44 m in total) was attached at the footrope to improve the catchability of deep-water shrimp.

The SCANMAR system was used on all trawl hauls. This equipment consists of sensors, a hydrophone, a receiver, a display unit and a battery charger. Communication between sensors and ship is based on acoustic transmission. The doors are fitted with sensors to provide information on their distance and a height sensor is fitted to the bottom trawl to measure the trawl opening and provide information on clearance and bottom contact.

The pelagic trawl is equipped with a trawleye that provides information on the trawl opening and the distance of the footrope to the bottom.
