The DR FRIDTJOF NANSEN RESEARCH PROGRAMME is sponsored by the Norwegian Agency for Development Cooperation (NORAD). The Food and Agriculture Organization of the United Nations (FAO) provide support to the Programme through Project GCP/INT/730/NOR: International Cooperation with the Nansen Programme: Fisheries Management and Marine Environment. This project is the follow-up to the Project NORAD/FAO/UNDP GLO/92/013. The Institute of Marine Research (IMR), Bergen, Norway is responsible for the implementation of the Programme in cooperation with FAO Fisheries Department and the local fisheries administrations. The aim of the Nansen Programme is to assist developing countries in fisheries research, management and institutional strengthening.

The programme has previously conducted the following surveys in the Gulf of Guinea:

Area	Period
Cape Verga (Rep. of Guinea) to Cape St. Paul (Ghana)	02 – 25 June 1981
Togo to Cameroon	07 – 20 August 1981
Côte d'Ivoire and Ghana	12 – 20 October 1989

CHAPTER 1 INTRODUCTION

Following a request from the Government of Ghana, later supported by the Governments of Benin, Togo and Côte d'Ivoire, IMR, NORAD and FAO agreed to conduct a survey in the western Gulf of Guinea covering the waters of the above four countries. The objectives of the survey had been previously discussed and agreed upon by responsible from Marine Fisheries Research Division in Tema, Ghana and responsible for the Nansen programme at IMR.

1.1 Objectives

The main objectives of the survey were to:

- Map the distribution and estimate the abundance of the main pelagic species.
- Describe the distribution, composition and abundance of the demersal fish stocks by a swept-area trawl programme.
- Map the general hydrographic regime by using a CTD-sonde to monitor the temperature, salinity and oxygen regimes at bottom trawl stations and some transects.
- Sampling of plankton at some bottom trawl stations.
- On-the-job training on the main survey routines.

1.2 Participation

The scientific staff consisted of:

Marine Fisheries Research Division, Tema, Ghana:

Kwame A. Koranteng, Paul O. Bannerman, Daniel W. Ofori-Adu, Joseph K. Teye

Direction l'Elevage de la Pêche, Lomé, Togo:

Yaovi Acakpo-Addra

Direction des Pêches, Cotonou, Benin:

Cossi Philippe Tohouegnon

FAO Fisheries Department (FIRM), Rome:

Merete Tandstad

Ecology and Epidemiology Group, University of Warwick, Coventry, UK:

Alan D. Lovell

Institute of Marine Research, Bergen:

Oddgeir Alvheim, Tore Mørk, Sigmund Mehl and Tore Nilsen

1.3 Narrative

The vessel left Tema (Ghana) on the afternoon of 19 April and steamed to the Benin-Nigerian border where the survey started at daylight 20 April. During daytime (0600 to 1800) the shelf was surveyed by parallel course tracks 24 NM (nautical miles) apart from approximately 20 m depth to beyond the 400 m isobath. Semi-random swept-area hauls were carried out on the shelf within the depth zones 20-30 m, 31-50 m and 51-100 m during daytime. In Ghana a few additional bottom trawl hauls were made deeper than 100 m at night-time in areas with suitable trawling grounds. Acoustic registration and integration of main groups were done throughout the survey. To obtain a better acoustic coverage, night-time registrations were made in between the daytime-course tracks. Pelagic trawling with the mid-water trawl was carried out during dark hours. The majority of the CTD-profiles were made at locations of fish-trawl stations, i.e. bottom trawls. In addition, some CTD profiles were made from surface down to depths of 500 m. In Ghana and Côte d'Ivoire a few plankton hauls were made at depths from 30 to 50 m.

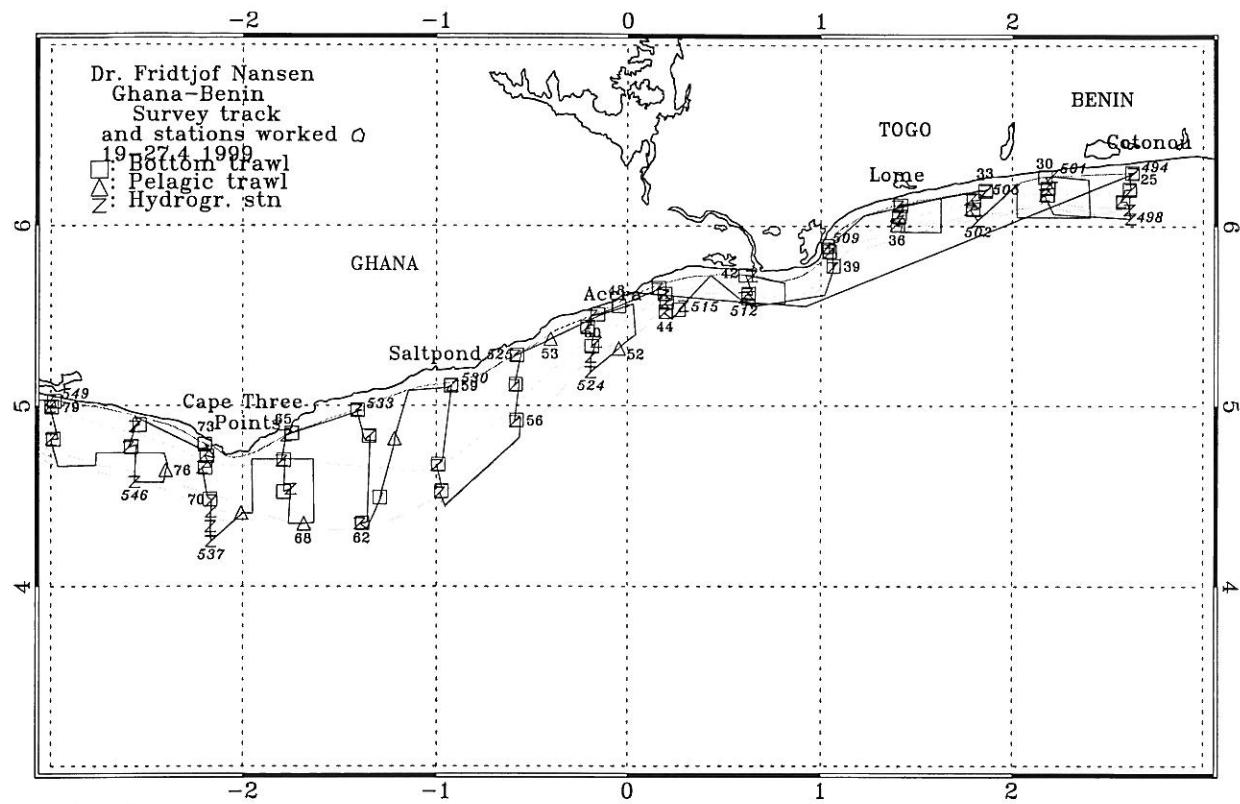

The shelf off Benin-Togo was covered from 20 to 21 April. One hydrographic transect was made in this area, off Cotonou. The shelf off Ghana was surveyed from 22 to 27 April. Two hydrographic transects were made in this area, off Accra and Cape Three Points. At noon on 27 April the vessel steamed from the Ghana-Côte d'Ivoire border to Abidjan for change of crew. The ship left Abidjan at noon on 29 April and steamed towards the Côte d'Ivoire-Liberia border where the survey continued 10 NM east of the border. The shelf off Côte d'Ivoire was covered from 30 April to 5 May and two hydrographic transects were made, off Grand Bérébi and Grand Jacques. The survey was completed at the Ghana-Côte d'Ivoire border at noon on 5 May and the vessel arrived in Tema in the morning of 6 May.

1.4 Survey effort

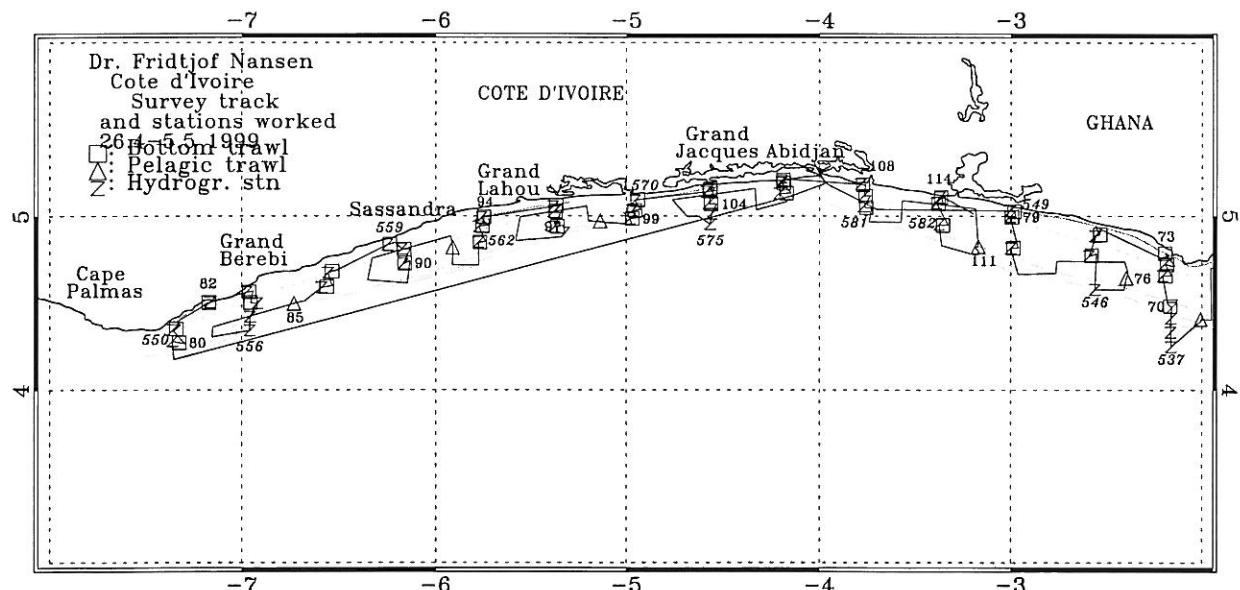

Figure 1 shows the cruise tracks with fishing, hydrographic and plankton stations. Table 1 summarises the survey effort in each sector.

Table 1. Number of hydrographic (CTD), plankton (P), pelagic trawl (PT) and bottom trawl (BT) stations, swept-area hauls (interrupted hauls not included) and distance surveyed (NM) by area.

Region	CTD	P	PT	BT	Swept-area hauls			Distance surveyed (NM)
					0-30 m	31-50 m	51-100 m	
Benin – Togo	15	-	-	12	4	4	4	300
Ghana	41	4	6	37	10	12	10	955
Côte D'Ivoire	35	4	4	31	9	11	11	810

CHAPTER 2 METHODS

2.1 Meteorological and hydrographical sampling

Temperature, salinity and oxygen

A Seabird 911 CTD plus was used to obtain vertical profiles of temperature, salinity and oxygen. Real time plotting and logging was done using the Seabird Seasave software installed on a PC. The profiles were usually taken down to a few metres above the bottom, but not deeper than 500 m. Two Niskin bottles were triggered for water samples at a few of the stations, one near the bottom and one near the surface (5 m depth). The samples were analysed for salinity using a Guildline Portasal salinometer, and the oxygen content was determined using the Winkler method. These laboratory values were used to calibrate the CTD, though after removing obvious outliers.

For oxygen, 15 samples out of 15 were accepted for the calibration. A linear regression gave the following formula for correcting the oxygen values:

$$O_2 = O_{2ctd} * 1.106 - 0.436$$

For the salinity calibration, a total of 12 out of 15 samples were accepted. The average difference between laboratory and CTD values was 0.003 with a standard deviation of 0.003, and hence the CTD values were accepted and used.

Current speed and direction measurements (ADCP)

A ship-born Acoustic Doppler Current Profiler (ADCP) from RD Instruments was activated on every CTD station with bottom depth greater than 50 m. The ADCP was set to ping every 8 seconds, the depth cell was chosen to 8 m and the number of cells to 50. As a routine the data were averaged over 300 seconds for analyses onboard. Both the raw and averaged data were stored on files. The data were analysed by the PC software UMS (Underway Mapping System).

Meteorological observations

Wind direction and speed, air temperature, global radiation and sea surface temperature (5 m depth) were logged automatically every nautical mile on an Aanderaa meteorological station.

2.2 Biological sampling

The trawl catches were sampled for species composition by weight and numbers. The deck sampling procedure is described in more detail by Strømme (1992). In general, for important species the fork length was recorded to the nearest 1 cm below for fish and carapace length to the nearest 1 mm below for shrimp. In addition, total length and total body weight (g) were recorded for the target species in the acoustic survey. Basic information recorded at each fishing station, i.e. trawl haul, is presented in Annex I. Pooled length frequency distributions, raised to catch per hour, of selected species by area are shown in Annex II. A description of the fishing gear used, acoustic instruments and their standard settings, is given in Annex IV.

2.3 Biomass estimates

Acoustic abundance estimation

The following target strength (TS) function was applied to convert s_A -values (mean integrator value for a given area) to number of fish (sardinella, anchovy, scombrids and carangids):

$$TS = 20 \log L - 72 \text{ dB} \quad (1)$$

or in the form $C_F = 1.26 \cdot 10^6 \cdot L^{-2}$ (2)

where L is total length and C_F is the fish conversion factor. The following formula was used to calculate the number of fish in length groups (cm) for each fish concentration:

$$N_i = A \cdot s_A \cdot \frac{p_i}{\sum_{i=1}^n \frac{p_i}{C_{Fi}}} \quad (3)$$

where:
 N_i = number of fish in length group i
 A = area (NM^2) of fish concentration
 s_A = mean integrator value (echo density) in area A (m^2/NM^2)
 p_i = proportion of fish in length group i in samples from the area
 C_{Fi} = fish conversion factor for length group i

The number per length group (N_i) was then summed and the total number of fish obtained:

$$N = \sum_{i=1}^n N_i \quad (4)$$

The length distribution of a given species within an area was computed by simple adding of the length frequencies obtained in each trawl sample within the area. In the case of co-occurrence of target species, the s_A value was split in accordance with length distribution and catch rate in numbers in the trawl catches. Biomass per length group (B_i) was estimated by applying observed weights by length (W_i) when available or theoretical weights (calculated by using condition factors), multiplied with number of fish in the same length group (N_i). The total biomass in each area was obtained by summing the biomass of each length group:

$$B = \sum_{i=1}^n N_i \bar{W}_i \quad (5)$$

The number and biomass per length group in each concentration were then added up to obtain totals for each region. The mean integrator value in each sampling unit (s_A -values) was divided between the standard categories/groups of fish, as noted below, on the basis of trawl catches and characteristics of echo traces.

- plankton
- sardinella (*Sardinella aurita* and *S. maderensis*)
- anchovy (*Engraulis encrasicolus*)
- Chub mackerel (*Scomber japonicus*)
- PEL 1 (other clupeids than sardinella and anchovy)
- PEL 2 (carangids, other scombrids than chub mackerel, barracudas, hairtail)
- mesopelagic fish
- demersal fish

Biomass estimates based on swept-area method

In the bottom trawl survey, stock biomasses were estimated by the swept-area method with catch per haul as the index of abundance (see Strømme 1992). The general formula to estimate biomass B , using this method is:

$$B = \frac{A}{a} \cdot \frac{\bar{X}}{q} \quad (6)$$

A is the total area surveyed, a is the swept area of the net per haul, \bar{X} is the average catch per haul (the index of abundance) and q is the proportion of fish in the path of the net that are actually caught. The density of the resource is estimated as biomass per unit area. In a stratified survey of k non-overlapping strata, if the mean catch per haul in stratum i and its

variance are denoted by \bar{X}_i and σ_i^2 respectively, then an unbiased estimate of the population mean \bar{X} is the stratified mean \bar{X}_{st} which is given by:

$$\bar{X}_{st} = \frac{1}{N} \sum_{i=1}^k N_i \bar{X}_i = \sum_{i=1}^k W_i \bar{X}_i \quad (7)$$

where $W_i = \frac{N_i}{N} = \frac{A_i}{A}$ is the relative size of the i^{th} stratum (A_i is the area of the i^{th} stratum and A is the total area surveyed). The variance of the stratified mean is given by

$$\text{var}(\bar{X}_{st}) = \sum_{i=1}^k W_i^2 \text{var} \bar{X}_i = \sum_{i=1}^k W_i^2 \frac{s_i^2}{n_i} \quad (8)$$

where n_i is number of hauls in the i^{th} stratum and n is the total number of hauls in the survey.

Table 2 shows the areas used in the swept-area method to estimate biomass for the different regions. A stratified semi-random design was used, with depth and main area as stratification factors. Estimated total biomass by species/group was obtained by summing estimates for each depth stratum.

The swept-area-per-haul (a) is calculated as the product of the distance covered during trawling and the distance between the wings of the trawl. The bottom trawl on R/V "Dr. Fridtjof Nansen" has an estimated headline height of 5 m and a distance between wings during towing of about 18 m. All trawl hauls were monitored by SCANMAR trawl sensors, allowing improved accuracy in determining the actual time the trawl was fishing on the bottom. A more detailed description of the fishing gear is given in Annex IV. For conversion of catch rates to fish densities the area between the wings is assumed to be the effective fishing area. The catchability coefficient q was assumed to be 1. The length of a haul, recorded as distance over the bottom, was measured by GPS.

Table 2. Area (NM^2) used in the swept-area biomass estimates for the different regions.

Depth stratum (m)	Benin-Togo	Ghana	Côte d'Ivoire
0 – 30	536	1 412	563
31 – 50	212	2 064	701
51 – 100	344	2 751	1 619

CHAPTER 3 OCEANOGRAPHIC CONDITIONS

Temperature and salinity

Surface distribution

Figures 2 and 3 show the horizontal distribution of sea surface temperature (SST) and salinity, respectively, for the Benin-Togo-Ghana and west Ghana-Côte d'Ivoire area. Generally, the temperature was around 29°C in both areas with slightly cooler waters towards the shore. In the Côte d'Ivoire sector, the SST was slightly lower and there were pockets of water within the vicinity of Abidjan, with temperature less than 28°C.

In the Benin-Togo-Ghana area, the salinity ranged from 35.2-35.4‰ near the shore to 34.7-34.8‰ on the outer part of the shelf. In the west Ghana-Côte d'Ivoire sector, the salinity generally varied between 35.0 and 35.2‰. In the central part of this sector, there were areas with surface water salinity of less than 35‰.

Vertical sections

In Fig. 4 the vertical distribution of temperature, salinity and oxygen are shown for the five hydrographic transects made during this survey. There are very little differences between the environmental profiles obtained from the five hydrographic transects. A thermo-cline was found between 20 and 60 m depth and a relatively flat structure was observed in most sections with no clear signs of vertical water displacement and upwelling. This is expected at this time of the year when the thermocline is strongest (Longhurst 1962, Mensah and Koranteng 1988). On the onset of upwelling, which usually occurs in the beginning June, the thermocline is expected to weaken.

There was no sign of low bottom oxygen content on the shelf. Dissolved oxygen values ranged between 2 and 5 ml/l (non-corrected).

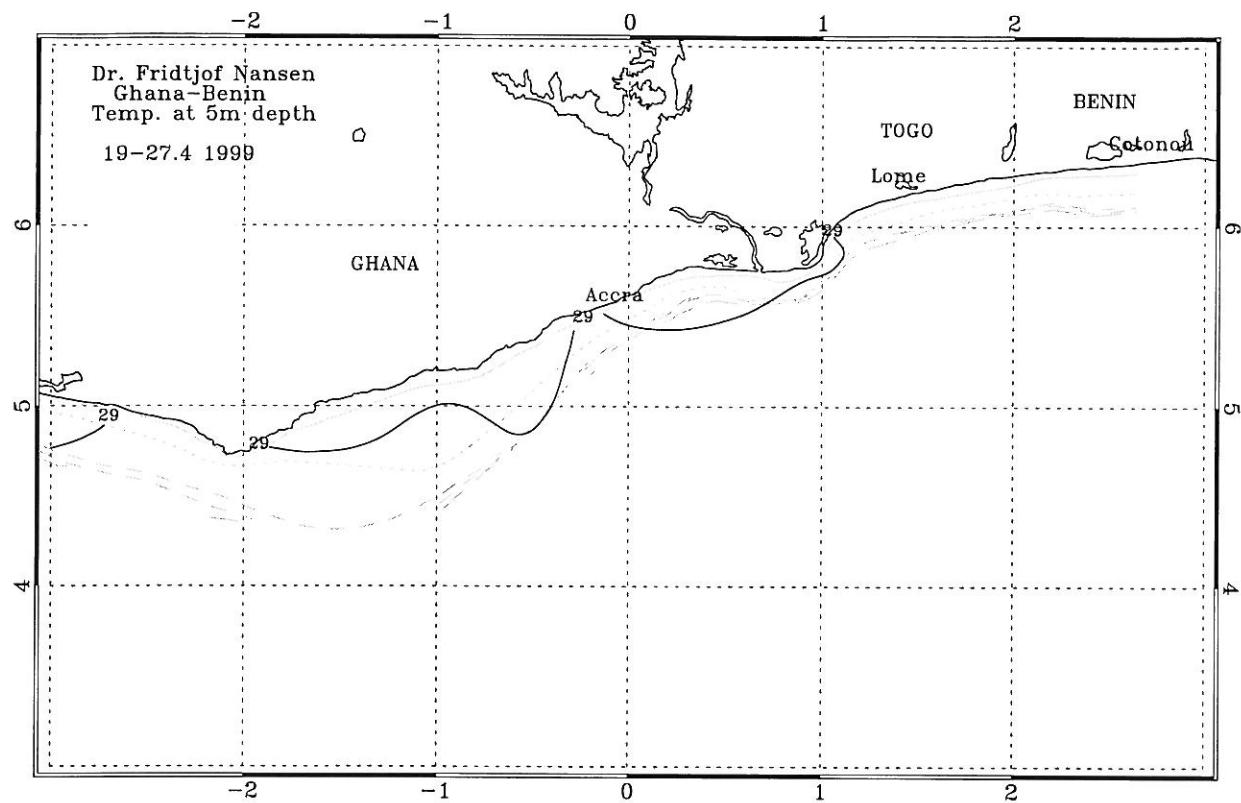

Current measurements (ADCP)

A subset of vectors obtained at 19 m depth is shown in Fig. 5. No averaging was done except the 5 minutes averaging done in real time. Therefore, at deep stations lasting more than 10 minutes, several vectors are plotted at the same position, and there is some variability both within and between stations due to variability in time and space.

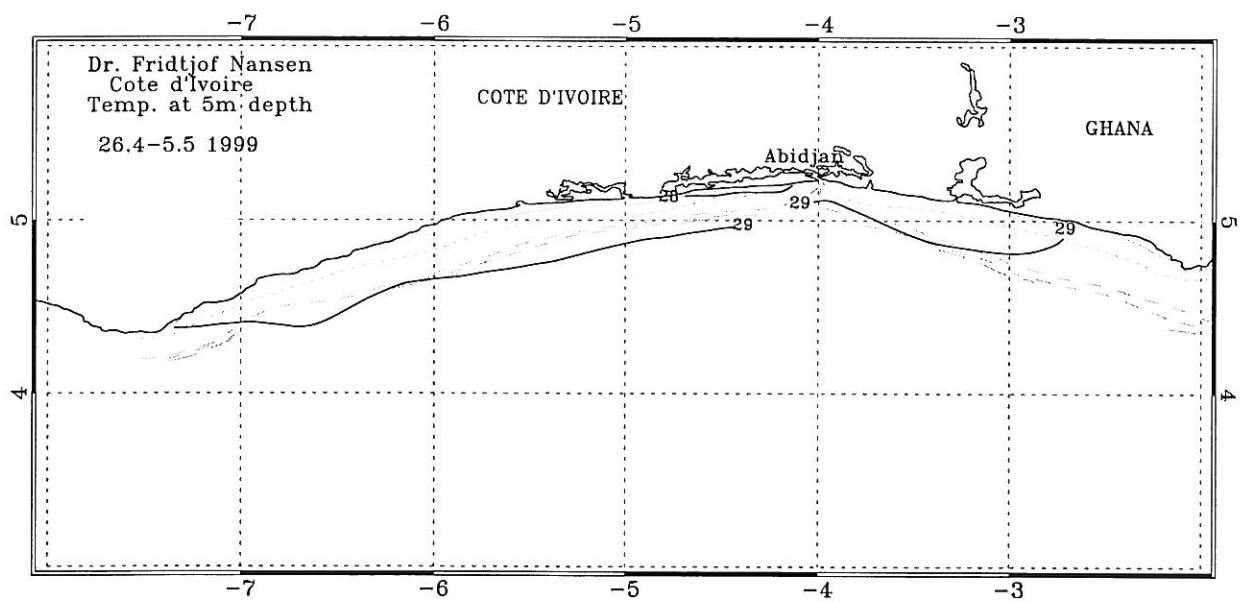

However, the vectors show a marked and strong current parallel to the coastline, and going from west to east. This is the Guinea Current. The strength of the current was about 2 NM/h

or approx. 1 m s^{-1} . This is in accordance to Anon (1996) that reported an average speed of the Guinea Current to be about 0.8 m s^{-1} , and that occasionally reaches a maximum of 1.0 m s^{-1} . It appears that the measurements close to the bottom have been taken within the Guinea-Under-Current that flows westward and underlies the Guinea Current. This is according to Binet and Marchal (1993) because the Guinea Current extends only to the 25 m depth offshore and is shallower closer inshore.

The intensity of the current to the immediate east of Cape Palmas (west off Côte d'Ivoire) and Cape Three Points (western Ghana) is quite significant. Marchal and Picaut (1977) argued that the dynamic interaction between the flow of the Guinea Current and these two large capes leads to a rise in the thermocline downstream and accumulation of water upstream. These events contribute to the oceanographic conditions in the area.

CHAPTER 4 RESULTS OF THE ACOUSTIC SURVEY: FISH DISTRIBUTION AND ABUNDANCE ESTIMATE OF PELAGIC SPECIES

Figures 6-8 illustrate the distribution and abundance of sardinellas, anchovies and fish category PEL 2 (mainly carangids) as observed with the acoustic integration system. The unit of acoustic reflection is m^2/NM^2 , and a scale normally used on acoustic surveys with R/V "Dr. Fridtjof Nansen" was used to illustrate different levels of concentration.

4.1 Benin - Togo

Clupeids

Both *Sardinella aurita* and *S. maderensis* were caught in small quantities in the bottom trawl hauls in Benin-Togo waters. *S. aurita* of 14-18 cm total length (TL) were found both on the inner and outer shelf, while juvenile *S. maderensis* (8-12 cm) were found only on the inner shelf. Some low-density fish schools in this area (Fig. 6a) were attributed to sardinella, but unfortunately no pelagic trawl hauls were made to establish the species composition and length distribution of the schools. The biomass of the two species together was estimated to be about 5 000 tonnes.

Ilisha africana was recorded in some of the bottom-trawl stations in Benin waters, but no s_A -values were attributed to this species and no estimate of abundance was made.

Anchovy

A few schools of juvenile (3-5 cm TL) *Engraulis encrasicolus* were recorded in shallow waters (20-30 m) at the Benin-Togo border (Fig. 7a). The biomass of these schools was estimated to be 250 tonnes.

PEL 2 (carangids, scombrids, barracudas and hairtail)

This group consisted mainly of carangids with *Selene dorsalis* and *Alectis alexandrinus* as the most abundant species in the bottom-trawl hauls. They were caught both on the inner and outer shelf. Other common carangids were *Chloroscombrus chrysurus* and *Decapterus macarellus*, while *Trachurus trecae* was found only at a couple of stations. Only one scombrid species, *Scomberomorus tritor*, was caught but again only at few stations. The

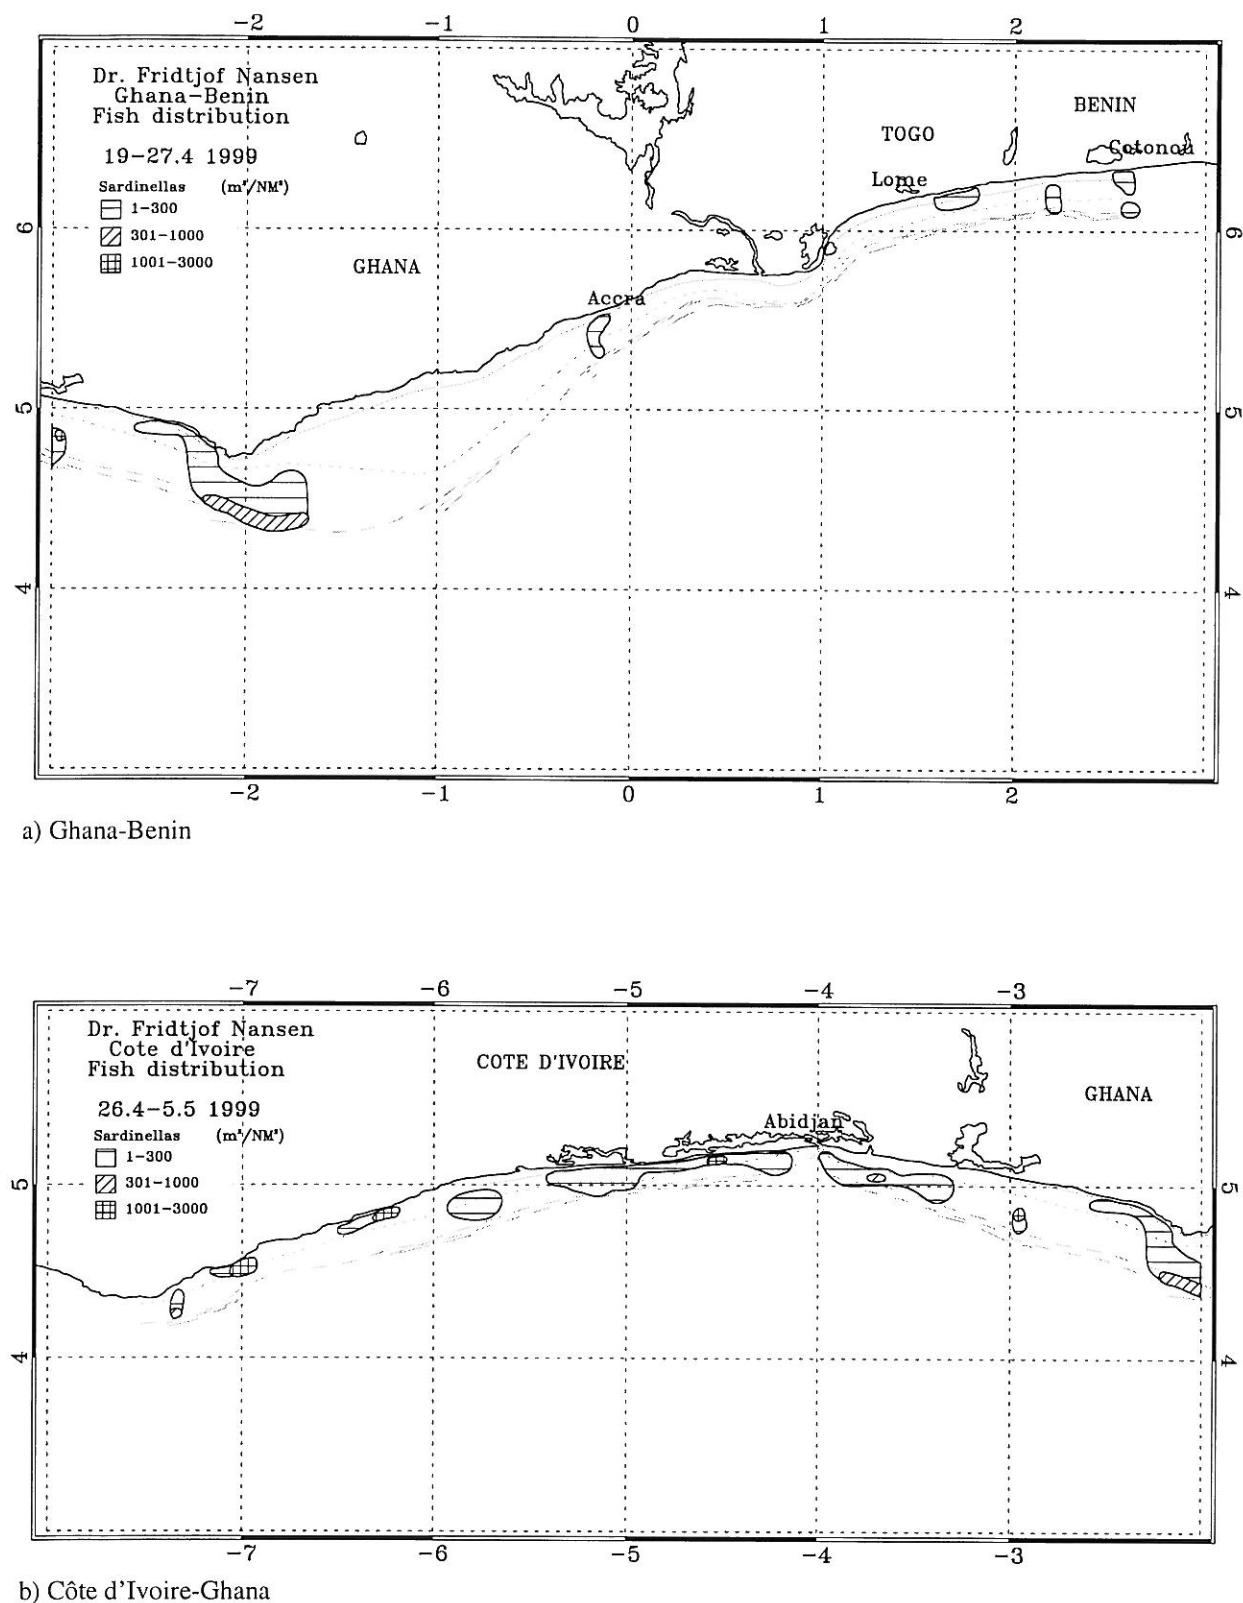

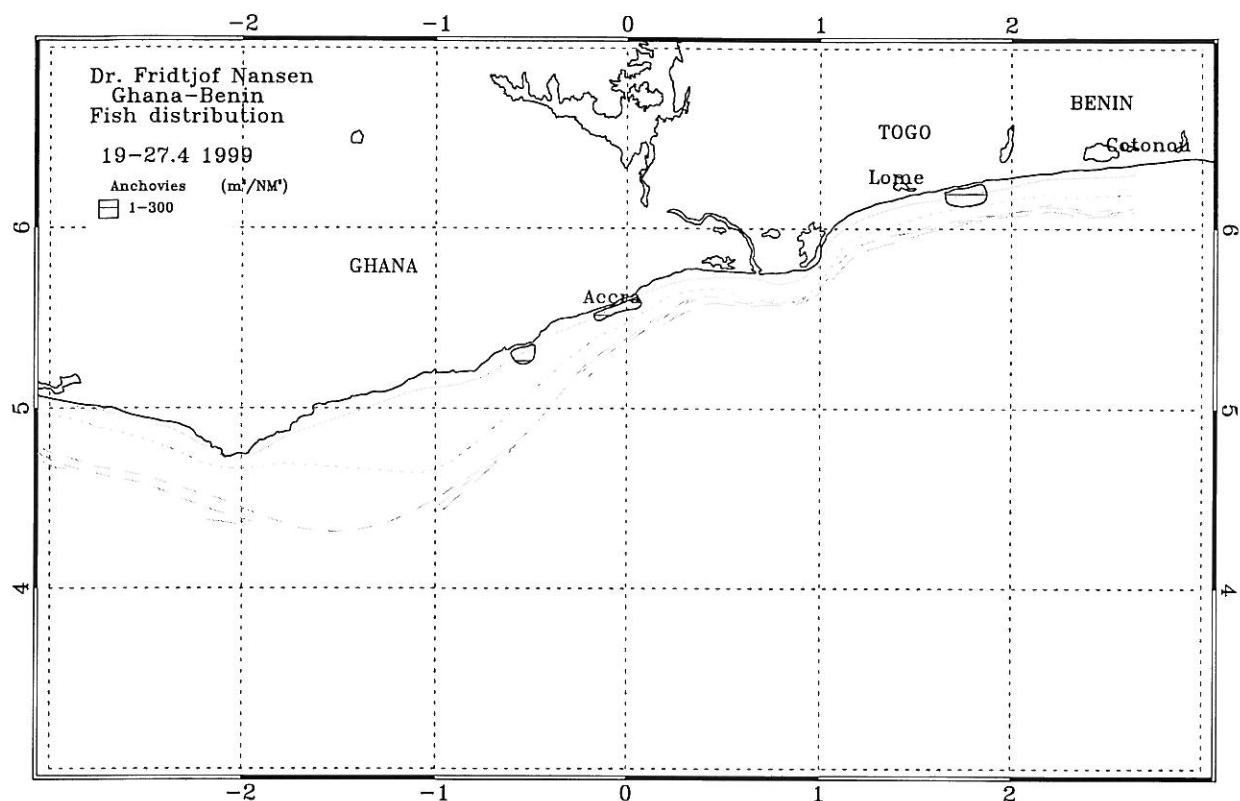

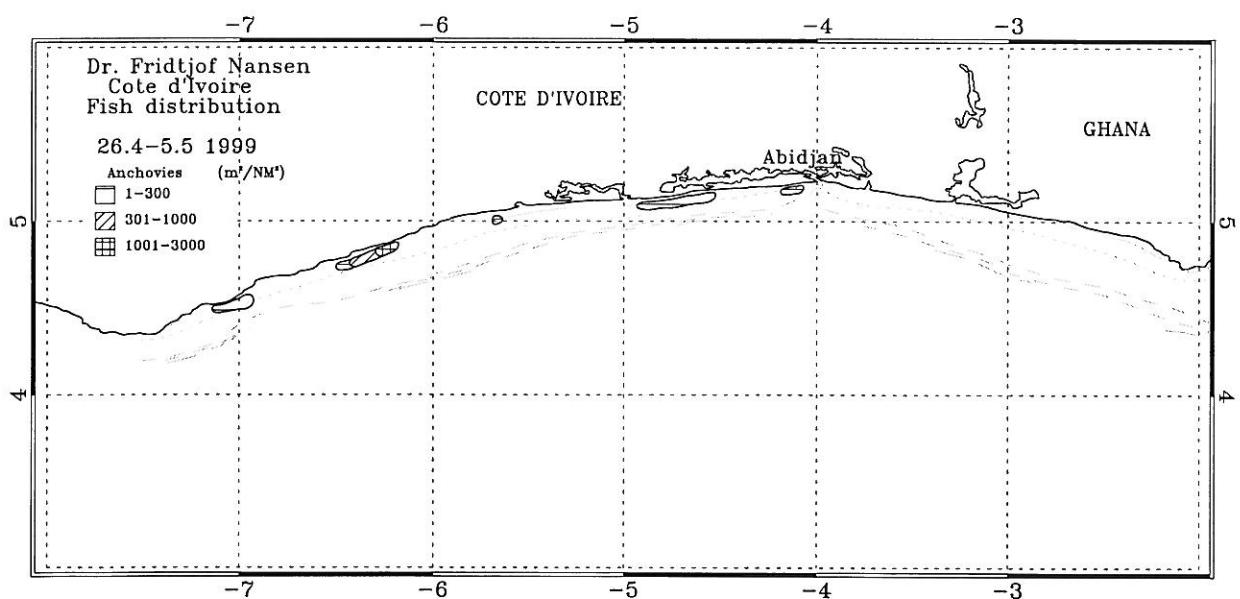

Figure 6. Distribution of *Sardinella* spp. off a) Ghana-Benin and b) Côte d'Ivoire. Depth contours as in Fig. 1.

b) Côte d'Ivoire-Ghana

Figure 7. Distribution of anchovy (*Engraulis encrasicolus*) off a) Ghana-Benin and b) Côte d'Ivoire. Depth contours as in Fig.1.

a) Ghana-Benin

b) Côte d'Ivoire-Ghana

Figure 8. Distribution of PEL 2 (Carangids, scombrids, barracudas and hairtail) off a) Ghana-Benin and b) Côte d'Ivoire. Depth contours as in Fig.1.

barracuda *Sphyraena guachancho* was common in most of the bottom-trawl hauls, while the hairtail *Trichiurus lepturus* was caught at one station only. A few larger schools and some smaller ones, all of low density, were attributed to this group (Fig. 8a). Based on length distributions of *Selene dorsalis* and *Alectis alexandrinus* from bottom trawl hauls (mean TL of about 30 cm), the biomass of this group was estimated to be about 3 900 tonnes.

4.2 Ghana

Clupeids

In addition to a few large pelagic catches, *S. aurita* was found at about two-thirds of the bottom-trawl stations, both on the inner and outer shelf. *S. maderensis* was much less abundant and was mainly found on the inner shelf. Several small and some larger schools of medium density were allocated to sardinella (Fig. 6a, b). The highest concentrations were recorded off Cape Three Points, where the main species was *S. aurita*, both juvenile of about 10 cm TL and adults of about 20 cm TL. Fig. 9 shows the length distribution of *S. aurita* as estimated from the acoustics. The total biomass of sardinellas was estimated to be about 40 000 tonnes.

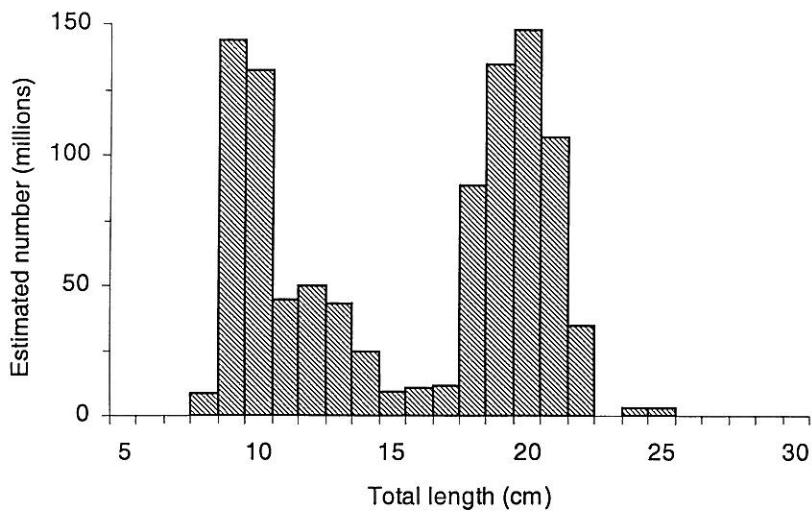

Figure 9. Length distribution (in million) of *Sardinella aurita* in the Ghana area, estimated acoustically.

Ilisha africana was caught in a few bottom trawl hauls in shallow waters, but no s_A -values were attributed to this species and no estimate of abundance was made.

Anchovy

Some schools of small *E. encrasiculus* (4-8 cm TL) were recorded in shallow waters off Accra (Fig. 7). The biomass of these schools was estimated to be about 400 tonnes. Anchovy was also caught in the bottom trawl at a couple of stations both east and west of Accra.

PEL 2 (carangids, scombrids, barracudas and hairtail)

As in Benin - Togo waters this group consisted mainly of carangids. In addition to *Alectis alexandrinus* and *S. dorsalis*, the species *Caranx cryos*, *Chloroscombrus chrysurus*, *D. macarellus*, *Selar crumenophthalmus* and *T. trecae* were relatively abundant in the bottom trawl catches in Ghana. *Scomberomorus tritor* was the most common scombrid in the bottom-trawl hauls, while a large quantity of *Scomber japonicus* was caught with the pelagic trawl during night-time. Most of the carangids were juveniles (5-15 cm). The barracuda *S. guachancho* was found in about half of the bottom-trawl hauls, while hairtail *T. lepturus* was only caught at a few stations. Schools of PEL 2 species were detected on most of the shelf, both on the inner and outer shelf (Fig. 8a, b). The schools were of low density, and the highest values were usually found on the outer shelf. The biomass of PEL 2 was estimated to approximately 50 000 tonnes, applying an over-all average length of 17 cm (pooled length distributions, weighted by catch, for carangids, scombrids, barracudas and hairtails). This estimate also includes a few larger and denser schools *S. japonicus*, 23-31 cm TL, recorded on the outer shelf off Cape Three Points. The total biomass of these schools was estimated to be about 6 000 tonnes and the estimated length distribution is shown in Fig. 10.

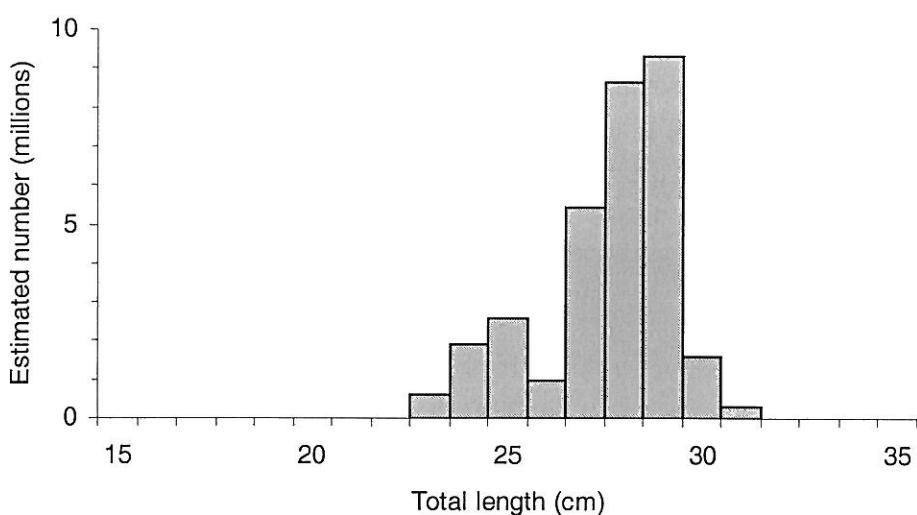

Figure 10. Length distribution (in million) of *Scomber japonicus* off Cape Three Points, estimated acoustically.

4.3 Côte d'Ivoire

Clupeids

Schools of sardinellas were recorded along the whole coast of Côte d'Ivoire, with highest concentrations in shallow waters in the western part of the area (Fig. 6b). Both *S. aurita* and *S. maderensis* occurred frequently in the bottom-trawl catches, and were also caught in a few pelagic-trawl hauls. *S. maderensis* was most abundant and dominated the inner shelf, while *S. aurita* was common on the outer shelf. Most of the sardinellas found on the shelf off Côte d'Ivoire were small in size (Fig. 11), and the total biomass was estimated to be about 37 000 tonnes.

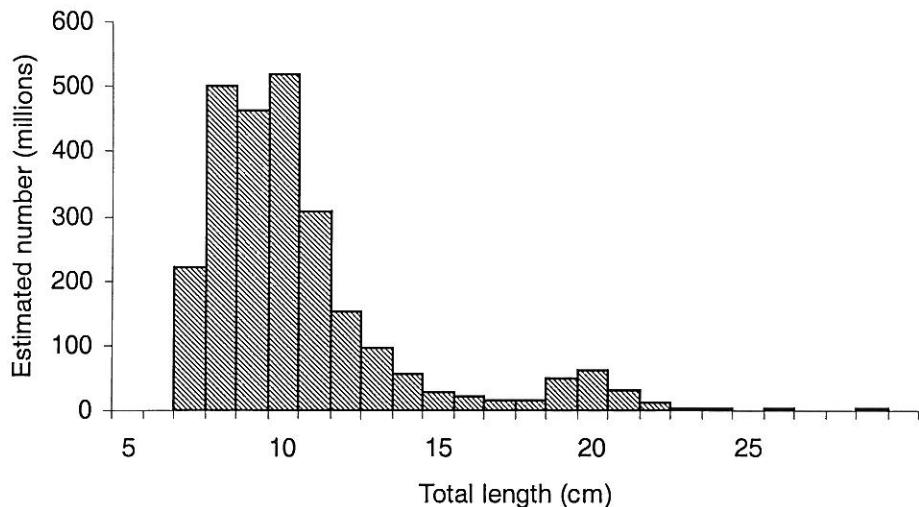

Figure 11. Length distribution of *Sardinella* spp. in the Côte d'Ivoire area, estimated acoustically.

Anchovy

Several schools of *E. encrasicolus* (5-11 cm TL) were recorded in shallow waters off Côte d'Ivoire. The main concentrations were found off Pointe Klama (10 NM west off Grand Bérébi), Sassandra and in the area between Grand Lahou and Abidjan (Fig. 7b). Anchovy was also caught at several of the bottom-trawl stations on the inner shelf (see Annex I). The biomass of anchovy was estimated to be 5 100 tonnes.

PEL 2 (carangids, scombrids, barracudas and hairtail)

Like in Benin-Togo and Ghana the species category PEL 2 consisted mostly of carangids, but also barracudas occurred in many of the bottom-trawl hauls with relatively high catch rates. The main species of carangids were *S. dorsalis*, *C. chrysurus* and *T. trecae*. Other carangids such as *A. alexandrinus*, *Caranx cryos*, *Selar crumenophthalmus* and *Decapterus* sp. also occurred but at lower densities. The two species of barracuda found are *Sphyraena guachancho* and *S. sphyraena*. The first was found in approximately half of the bottom-trawl stations and the second species at about one quarter of the stations. The most common species of scombrids were *Scomberomorus tritor* and *Scomber japonicus*, occurring less frequently than the barracudas and at lower catch rates. The hairtail, *T. lepturus*, was found at about one third of the bottom-trawl stations and at low-to-moderate densities.

Schools of PEL 2 species were found on most of the shelf, both on the inner and outer shelf. The schools were of low-to-medium densities; the highest densities usually found on the outer shelf (Fig. 8a). Applying an over-all average length of 14 cm (pooled length distributions, weighted by the catch, for carangids, scombrids, barracudas and hairtails), the biomass of PEL 2 was estimated to be approximately 30 000 tonnes.

4.4 Review of results

Table 3 presents estimated biomass of PEL 1 species (sardinellas and anchovies) and PEL 2 species (carangids, scombrids, barracudas and hairtails) based on the 'Dr. Fridtjof Nansen' surveys in 1981 (Strømme 1984), 1989 (Anon. 1989) and 1999 (this survey). The Benin-Togo sector was covered only during the present survey.

As in 1989, pelagic fishes were present over large parts of the area, especially the central and western parts. In addition to schools recorded with the acoustic system, pelagic fish also occurred in dispersed distributions. This was confirmed by random pelagic trawl hauls made in the area. Sardinellas and anchovy dominated on the inner shelf, while carangids, scombrids and barracudas were more widely distributed over the entire shelf. Triggerfish (*Balistes capriscus*) was found only at a few stations in each area. In Ghana the biomasses estimated in this survey are similar to those estimated in 1989 and about twice the 1981 estimates. In Côte d'Ivoire the total biomass of sardinellas and anchovy was much higher in the present survey than in 1989 but at the same level as in 1981, while the PEL 2 biomass was slightly lower than in 1989 and much higher than in 1981. The total biomass of pelagic fish in the Ghana-Côte d'Ivoire area has increased by almost 80% since 1981, mainly due to an increase in the biomass of carangids. As previously indicated by Anon. (1989) this increase may be related to

the decrease in the stock of triggerfish, from 500 000 tonnes in 1981 to 140 000 tonnes in 1986 (Oliver and Miquel 1987) and almost nothing in 1989 and 1999. The distribution of carangids was found to cover the whole shelf area, as for the triggerfish.

Table 3. Acoustic biomass estimates of main pelagic groups a) Sardinellas and anchovies (PEL 1) and b) carangids, scombrids, barracudas and hairtail (PEL 2) from surveys with "DR. Fridtjof Nansen" off Côte d'Ivoire, Ghana, and Benin-Togo in June 1981, October 1989 and this current survey in April/May 1999. Note that Benin-Togo was only covered during this present survey.

a) Sardinellas and anchovies (PEL 1)

Survey Year	Survey period	Côte d'Ivoire	Ghana	Benin - Togo	Total
1981	June	39 000	40 000	not covered	79 000
1989	12 – 20.10	6 000	41 000	not covered	47 000
1999	19.4 – 6.5	42 000	40 000	5 000	87 000

b) Carangids, scombrids, barracudas and hairtail (PEL 2)

Survey Year	Survey period	Côte d'Ivoire	Ghana	Benin - Togo	Total
1981	June	2 000	10 000	not covered	12 000
1989	12 – 20.10	33 000	57 000	not covered	90 000
1999	19.4 – 6.5	30 000	50 000	4 000	84 000

CHAPTER 5 RESULTS FROM THE TRAWL SURVEY: CATCH DISTRIBUTION, COMPOSITION AND SWEPT- AREA BIOMASS ESTIMATES OF DEMERSAL FISH

The composition of the fish fauna on the continental shelf and slope of the western Gulf of Guinea changes with depth (Williams 1968). The catch-distribution analyses were therefore performed for two depth strata on the shelf, 0-50 m (inner shelf) and 51-100 m (outer shelf). In the analyses the “Demersal” group comprises commercially important families as Sciaenidae, Haemulidae (=Pomadasytidae), Serranidae, Sparidae and Lutjanidae, while the “Pelagic” group includes Engraulidae, Clupeidae, Carangidae, Scombridae, Sphyraenidae and Trichiuridae (the latter family is actually mainly benthopelagic). For the different analysis the “other” group includes all species not accounted for in the groups listed. Therefore the content of “other” will change from table to table.

The locations of the trawl stations are shown in Fig. 1. Records of fishing stations and catches are presented in Annex I and pooled length distributions (weighted by catch) of main species by area are shown in Annex II.

In the swept-area biomass estimates, only the shelf area down to depths of 100 m was included, divided into 0-30 m, 31-50 m and 51-100 m. Mean densities of the main demersal species by depth strata, occurrence and catch distributions are shown in Annex III.

5.1 Benin - Togo

In the Benin-Togo area, 12 swept-area trawl stations were successfully fulfilled on the shelf, while no hauls were made in areas deeper than 100 m due to a steep slope and rough bottom. Tables 4a and b show catch rates by main groups for the inner shelf (20-50 m) and outer shelf (51-100 m) respectively.

The pelagic group dominated on the inner shelf with a relative contribution of 38%. The group “other” was the second most important, contributing to 33% of the catches, while the demersal group made up 26%. Shrimps and cephalopods had small average catch rates, and no sharks were caught on the inner shelf. On the outer shelf the demersal group was the most important with 45% of the average catch rate. The pelagic group made up 28% of the catches, cephalopods 20% and non-commercial fish 7%. *Alloteuthis africana* and *Sepia officinalis hierredda* were the dominant cephalopods. The catch rate of sharks was low, and no commercially important shrimps were caught in this zone.

Table 4. Benin – Togo. Catch rates (kg/hour) by main groups in swept-area bottom trawl hauls on a) inner shelf, 0-50 m, and b) outer shelf, 51-100 m. SE = standard error.

a) Inner shelf, 0-50 m

Catch rates of the most important pelagic families, caught by bottom trawl in the swept-area survey, are presented in Tables 5a and b. Carangids dominated both on the inner and outer shelf, and the average catch rate was slightly higher on the latter than the former. *S. dorsalis* and *A. alexandrinus* occurred most frequently and had the highest catch rates. Barracudas (Sphyraenidae) were the second most important group, with the highest average catch rate on the inner shelf. The catch rates and frequency of occurrence of clupeids, scombrids and hairtails were all low, and no scombrids and hairtails were caught on the outer shelf. The clupeids consisted of *Sardinella aurita*, *S. maderensis*, *Ilisha africana* and *Engraulis encrasicolus*, while *Scomberomorus tritor* was the only species in the Scombridae family.

Tables 6a and b present catch rates of the most commercially important demersal species on the shelf down to depths of 100 m, grouped as seabreams (Sparidae except *Boops boops*), snappers (Lutjanidae), groupers (Serranidae), grunts (Haemulidae except *Brachydeuterus auritus*) and croakers (Sciaenidae). All groups had low catch rates on the inner shelf. Seabreams had the highest average catch rate, followed by croakers and groupers. The catch rates of grunts and snappers were very low on the inner shelf, and together with croakers, these groups were not found on the outer shelf. Seabreams were more abundant on the outer shelf and dominated with an average catch rate of 57 kg/h, or 30% of the total average catch rate. The most common species were *Pagellus bellottii*, *Dentex angolensis*, *D. canariensis* and *Pagrus caeruleostictus*. Groupers were also more abundant on the outer than on the inner shelf, with an average catch rate of 25 kg/h. *Epinephelus aeneus* was the dominant species in this group.

¹ Corrected

In Annex IIIA, swept-area estimates of mean densities based on 12 random bottom trawl hauls are presented for the demersal species on the shelf, to depths of 100 m. *Galeoides decadactylus*, *Polydactylus quadrifilis* and *P. senegalensis* had the highest densities in the shallowest depth zone (≤ 30 m), *P. caeruleostictus* and *B. auritus* in the 31-50 m zone, while *Dentex angolensis* had the highest density in the 51-100 m zone, followed by *Epinephelus aeneus*, *Alloteuthis africana* and *P. bellottii*. *E. aeneus* had the highest over all mean density, closely followed by *P. caeruleostictus*, *D. angolensis* and *A. africana*.

Table 7 presents swept-area biomass estimates for valuable demersal groups and other groups that occurred in sizeable quantities. Estimated total biomass of valuable demersal groups was only about 1 500 tonnes, with approximately 70% in Benin and 30% in Togo waters. Seabreams had highest biomass, followed by groupers and croakers. Seabreams and groupers

had the highest biomass in the deepest zone (51-100 m), while croakers, grunts and snappers were found only in the shallowest zone (≤ 30 m). Of the pelagic and semi-pelagic groups, carangids had the highest estimated biomass.

5.2 Ghana

Thirty-two swept-area trawl stations were made on the shelf off Ghana. In addition a couple of bottom-trawl hauls were made in waters deeper than 100 m. Tables 8a and b present catch rates by main groups for the inner and outer shelf. On the inner shelf the “other” species group (after considering the main groups) had the highest average catch rate with a relative contribution of 39%. The pelagic and demersal groups had about the same share of the catch (30 and 26%, respectively). Cephalopods made up about 10% of the catch, while shrimps and sharks were scarce. On the outer shelf the demersal group dominated with 82% of the overall average catch rate due to some large catches of *Brachydeuterus auritus*. Both the pelagic and “other” group had similar average catch rates as on the inner shelf, while catch rates of cephalopods were several times higher than on the inner shelf (37 kg/h). *Alloteuthis africana* and *Sepia officinalis hierredda* were the dominating cephalopods. The catch rate of sharks was also low on the outer shelf, and no commercially important shrimps were caught on this part of the shelf.

Table 8. Ghana. Catch rates (kg/hour) by main groups in swept-area bottom-trawl hauls on the a) inner shelf (0-50 m) and b) outer shelf (51-100 m).

Tables 9a and b show catch rates of the most important pelagic families caught in the bottom-trawl hauls. Carangids dominated both on the inner and outer shelf with similar catch rates of about 30 kg/h. The most abundant species were *Alectis alexandrinus*, *Chloroscombrus chrysurus*, *Decapterus macarellus*, *Selar crumenophthalmus*, *Selene dorsalis* and *Trachurus trecae*. Barracudas constituted the second most important group on the inner shelf, closely followed by clupeids. Clupeids had somewhat higher catch rates on the outer shelf and formed the second most important pelagic group here, while barracudas came third. The most frequently found clupeid was *Sardinella aurita*, while *S. maderensis* and *Ilisha africana* were less abundant. Hairtails (*Trichiurus lepturus*) occurred in low numbers at only two stations, one on the inner and one on the outer shelf. Scombrids were caught at about half of the stations on the inner shelf but not on the outer shelf. The most abundant species in this group was *Scomberomorus tritor*. The seemingly high catch rate of over 5 500 kg/hr of other was mainly due to a large catch of *Brachydeuterus auritus* off Saltpond (Table 8b).

Table 9. Ghana. Catch rates (kg/hour) by main pelagic families in swept-area bottom-trawl hauls on the a) inner shelf (0-50 m) and b) outer shelf (51-100 m).

Catch rates of the most valuable demersal groups on the shelf are presented in Tables 10a and b. Like in Benin-Togo waters the average catch rates were low on the inner shelf. Seabreams had the highest average catch rate. Grunts came second due to one large catch of mainly *Pomadasys jubelini* and some *P. incisus* and *P. rogeri*. Groupers had the third highest average catch rate on the inner shelf, but much lower than the first two groups. Seabreams dominated on the outer shelf with an average catch rate of 72 kg/h. *Dentex angolensis*, *D. canariensis*, *Pagellus bellottii* and *Pagrus caeruleostictus* were the most common species. Groupers with *Epinephelus aeneus* constituted the second most important demersal group on the outer shelf. Snappers and croakers were only caught in low numbers at a few stations on both the inner and outer shelf.

Annex IIIB gives the swept-area estimates of mean densities based on 32 random trawl stations for demersal species on the shelf. *B. auritus*, *Drepane africana*, *S. officinalis hierredda* and *D. canariensis* had the highest densities in the shallowest depth zone; *P. jubelini*, *B. auritus*, and *P. caeruleostictus* in the 31-50 m zone, while *B. auritus* dominated in the 51-100 m zone. These were followed by *P. bellottii*, *S. officinalis hierredda*, *Fistularia petimba*, *P. caeruleostictus*, *Pseudupeneus prayensis*, *Priacanthus arenatus*, *A. africana* and *D. angolensis*. *B. auritus* had the highest over all mean density, followed by *P. bellottii* and *S. officinalis hierredda*.

Table 10. Ghana. Catch rates (kg/hour) of valuable demersal species grouped by families in swept area bottom trawl hauls on the shelf. A: Inner shelf (0-50 m), B: Outer shelf (51-100 m).

Table 11 presents swept-area biomass estimates for valuable demersal groups. Estimated total biomass was about 10 000 tonnes of which Seabreams made up almost 80%. The highest biomass of seabreams was found between depths of 51 and 100 m. Grunts had the second highest biomass with almost 1 400 tonnes, followed by groupers, while snappers and croakers both had low biomass estimates. Of the pelagic and semi-pelagic groups, Bigeye grunt (*B. auritus*) dominated with an estimated biomass of more than 70 000 tonnes. However, the 95% confidence limits show that this estimate is quite uncertain since it is based on a few very large catches. The biomass of carangids was estimated to be about 7 000 tonnes.

5.3 Côte d'Ivoire

A total of 31 swept-area trawl hauls were carried out on the shelf of Côte d'Ivoire. No trawl hauls were made in waters deeper than 100 m. Tables 12a and b show catch rates by main groups for the inner (20-50 m) and outer (51-100 m) shelf. The pelagic group had highest average catch rate on the inner shelf with a relative contribution of 62% (Table 12 a). The demersal group was the second most important group contributing to 21% of the catches, followed by the group "other", which had a relative contribution of 16%. Both shrimps and cephalopods had low average catch rates, and no sharks were found on this part of the shelf. On the outer shelf the demersal group had the highest average catch rate, contributing 60% to the total (Table 12 b). The pelagic group and the group "other" contributed 24% and 14% respectively. The average catch rate of shrimps on the outer shelf was very low, whereas the catch rate of cephalopods was somewhat higher with a relative contribution of 1.5% as compared to 1% on the inner shelf. Sharks contributed 0.7% to the total on this part of the shelf. The species of shrimp found in Côte d'Ivoire were *Penaeus notialis*, *Penaeus kerathurus* and *Parapenaeopsis atlantica* and the main species of cephalopods were *Sepia officinalis hierredda*, *Octopus vulgaris* and *Alloteuthis africana*.

Tables 13a and b show the catch rates of the most important pelagic families caught in the bottom trawls. The clupeids were the dominant pelagic group on the inner shelf with an average catch rate of around 150 kg/h (Table 13a). The clupeid species that occurred most frequently and with the highest catch rates were the sardinellas, *Sardinella aurita* and *S. maderensis* and the anchovy, *Engraulis encrasicolus*. *Ilisha africana* and *Ethmalosa fimbriata* were also found. The second most important group was the carangids, which contributed 15% to the total. The most frequently caught species of this group were *Chloroscombrus chrysurus* and *Selene dorsalis*, which also had the highest catch rates. Barracudas had a relative contribution of 5%, while scombrids and hairtails contributed little to the total catch. The carangids had the highest average catch rate on the outer shelf (73 kg/h) followed by the clupeids (31 kg/h). The most frequently caught carangid on the outer shelf was *Trachurus trecae*, which also had the highest catch rates of this group. The main clupeid species was *S. aurita*. The catch rate of barracudas on the outer shelf was 1 kg/h, which is lower than on the inner shelf where the catch rate was 18 kg/h. As for the inner shelf, scombrids and hairtails contributed little to the total catch.

Table 13. Côte d'Ivoire. Catch rates (kg/hour) by main pelagic families in swept-area bottom-trawl hauls on the
a) inner shelf (0-50 m) and b) outer shelf (51-100 m).

Catch rates of the most valuable demersal groups on the shelf are presented in Tables 14a and b. From Table 14a it can be seen that the catch rates of the valuable demersal species on the inner shelf were low. This is similar to what was observed in Togo-Benin and Ghana. Grunts (excluding *Brachydeuterus auritus*) had highest catch rate of 10.3 kg/h, and a relative contribution to the total catch of 2.8%. The most frequently occurring grunts were *Pomadasys rogeri* and *P. jubelini*, the latter generally having the highest catch rate of the two. Croakers constituted the second most important group followed by seabreams, snappers and groupers. On the outer shelf, seabreams were dominant with a relative contribution of 14% and an average catch rate of 63 kg/h. *Dentex angolensis*, *Pagellus bellottii* and *D. canariensis* were the most frequently occurring species. Croakers, with *Pteroscion mbizi* and *Umbrina canariensis*, constituted the second most important group followed by the groupers. The catches of snappers and grunts were negligible on the outer shelf.

Table 14. Côte d'Ivoire. Catch rates (kg/hour) of valuable demersal species grouped by families in swept-area bottom-trawl hauls on the a) inner shelf (0-50 m) and b) outer shelf (51-100 m).

a) Inner shelf 0-50 m

Appendix III B gives the swept-area estimates of mean densities (t/NM^2) based on 31 random trawl stations for demersal species on the shelf. *B. auritus* had the highest mean densities in all the three depth zones (0-30 m, 31-50 m and 51-100 m) followed by *Galeoides decadactylus* and *Drepane africana* in the shallowest depth zone; *G. decadactylus* and *Elops lacerta* in the 31-50 m zone and *Priacanthus arenatus*, *D. angolensis* and *P. bellottii* in the 51-100 m zone. *B. auritus* had the highest over all mean density, followed by *Priacanthus arenatus* and *G. decadactylus*.

Table 15 presents the swept-area biomass estimates for the valuable demersal groups and other groups that occur in sizeable quantities. The estimated total biomass of valuable demersal groups was about 6 000 tonnes of which seabreams made up about 70%. The highest biomass of seabreams was found between depths from 51 to 100 m. Croakers had the second highest biomass with 950 tonnes followed by grunts, groupers and snappers. Croakers had the highest biomass in the 0-30 m depth interval followed by grunts, while grunts and seabreams had the highest biomass between 31-50 m. In the deepest depth interval (51-100 m), seabreams had the highest biomass, followed by croakers and groupers. No grunts or snappers were found at these depths.

Of the pelagic and semi-pelagic species, the bigeye grunt (*B. auritus*) had the highest estimated biomass followed by the carangids.

Table 15. Côte d'Ivoire. Biomass estimates (tonnes) of important species/groups of fish on the shelf, by depth.

5.3 Review of results

Table 16 summarizes the catch rates of valuable demersal groups and a few other common groups in the three regions covered during the present survey. Average catch rates for the whole shelf area from 20 to 100 m is used in the comparisons.

Table 16. Catch rates (kg/h) of valuable demersal and some other groups in swept-area bottom -trawl hauls on the shelf (20-100 m) off Benin-Togo, Ghana and Côte d'Ivoire.

Group/species	Benin-Togo	Ghana	Côte d'Ivoire
Seabreams ¹	28.6	32.8	26.1
Grunts	0.9	7.1	6.6
Croakers	4.6	0.7	9.5
Groupers	10.3	2.5	2.5
Snappers	0.3	0.7	2.3
Sum dem. val.	44.7	43.8	47.0
Bigeye grunt	5.5	213.4	91.9
Carangids	37.0	33.3	62.2
Barracudas	6.3	5.9	13.2

¹ Corrected

The highest overall catch rate of valuable demersal fish was in Côte d'Ivoire waters of 47.0 kg/h, and consisted mainly of seabreams and croakers. The corresponding rate in the Ghana and Benin-Togo sectors was almost the same, 44-45 kg/h in each sector, with seabreams and grunts as major groups in the Ghana catches and seabreams and groupers in the Benin-Togo catches.

Of the separate species groups, the highest catch rate of seabreams was in Ghana (32.8 kg/h), followed by Benin-Togo (28.6 kg/h) and then Côte d'Ivoire (26.1 kg/h). The catch rate of snappers showed the same trend between the areas. The Benin-Togo sector had the highest catch rate of groupers, being over four times higher than the rate in Ghana and Côte d'Ivoire. For grunts and the bigeye grunt (*Brachydeuterus auritus*) catch rates were highest in Ghana, 7.1 and 213.4 kg/h respectively. The corresponding rates were 6.0 and 91.9 kg/h for Côte d'Ivoire, and 0.9 and 5.5 kg/h for Benin-Togo. Carangids and barracudas were most abundant in Côte d'Ivoire followed by the Benin-Togo and least abundant in Ghana.

Generally, the area beyond the 100 m depth in all three sectors was not trawlable. Two hauls were made east of Tema (Ghana) at 310 and 105 m depths. At those two stations, the average catch rates were 312.3 and 17.1 kg/hr for demersal and pelagic species respectively.

Appreciable catch rates were obtained for deep-water sharks (e.g. *Centrophorus squamosus*), seabreams (*Dentex congensis* and *D. angolensis*) and deep-water shrimps (e.g. *Parapenaeus longirostris*).

Considering the limited area available for trawling beyond 100 m depth, it appears unlikely that a viable deep-water fishery can exist in this area in the western Gulf of Guinea. However, a better coverage is needed in order to reach a solid conclusion on this matter.

Table 17 summarizes the biomass estimates for the three sectors covered in this survey. The shelf area in each sector is also given. Due to a much shorter coastline and also a narrower shelf than off Ghana, Benin-Togo had the lowest biomass of most fish groups. The biomass of croakers was highest off Côte d'Ivoire. Bigeye grunt was more abundant in Ghana than in the two other areas.

Table 17. Biomass estimates (tonnes) of valuable demersal and some other groups in swept-area bottom-trawl hauls on the shelf (20 - 100 m) off Benin - Togo, Ghana and Côte d'Ivoire. The shelf area (NM²) in each area is given.

Group/species	Benin – Togo	Ghana	Côte d'Ivoire	Total

¹ Corrected

Table 18 summarizes the average densities of valuable demersal groups and a few other ones for the whole area covered during the present survey. For comparison, corresponding average densities found on the shelf of Congo-Gabon (Mehl 1995) and Angola (Mehl 1997) in recent years are also given. The total density of valuable demersal groups was highest in Angolan waters and lowest in the western Gulf of Guinea area. This was mainly due to much lower catch rates of seabreams and croakers, although the catch rates of grunts (excluding bigeye grunt), were also lower in the western Gulf of Guinea than off Angola. Even though the catch rates of groupers and snappers were low in this survey, they were similar to those obtained in the other two areas.

Among the other groups, the average density of bigeye grunt (*B. auritus*) was almost the same as found in Angolan waters but much higher than off Congo-Gabon. The densities of carangids caught in the bottom trawl were much lower than on the Angolan shelf but higher than what has been obtained in Congo-Gabon waters. The density of barracudas was low, but higher than off Congo-Gabon and lower than off Angola.

Table 18. Average densities (tonnes/NM²) of valuable demersal species, and some other groups in swept-area bottom-trawl hauls on the shelf off Benin-Togo-Ghana-Côte d'Ivoire, Congo-Gabon, and Angola.

Group / species	Benin-Togo-Ghana-Côte d'Ivoire 1999 (20-100m)	Congo - Gabon 1994 - 1995 (20-200m)	Angola 1995-96-97 (20-100m)

Annex II Length distributions of main species

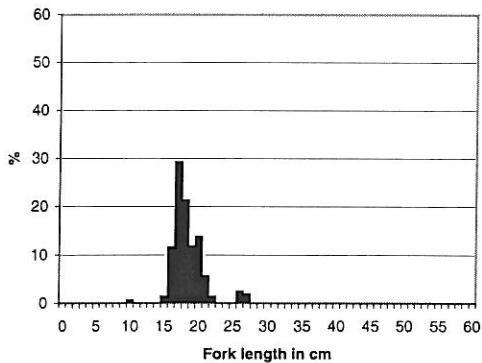

Pagellus bellottii
Mean length = 16.2 cm

Benin - Togo
N = 171

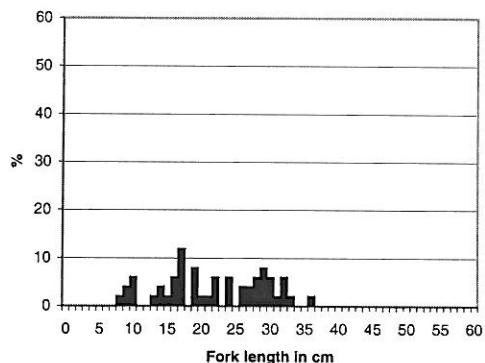

Pagrus caeruleostictus
Mean length = 25.7 cm

Benin - Togo
N = 124

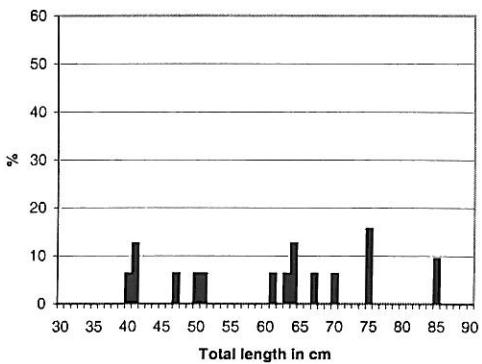

Dentex angolensis
Mean length = 18.9 cm

Benin - Togo
N = 66

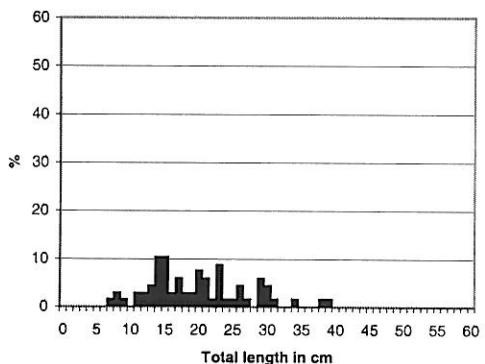

Dentex canariensis
Mean length = 22.3 cm

Benin - Togo
N = 51

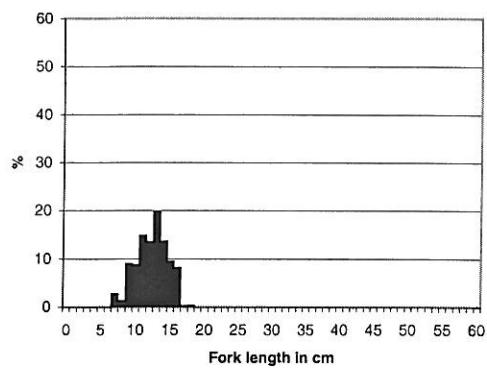

Epinephelus aeneus
Mean length = 61.4 cm

Benin - Togo
N = 15

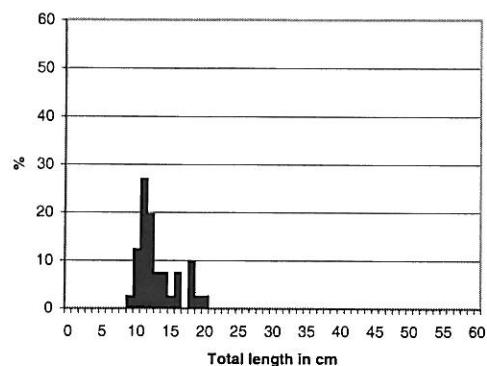

Pseudotolithus senegalensis
Mean length = 20.3 cm

Benin - Togo
N = 68

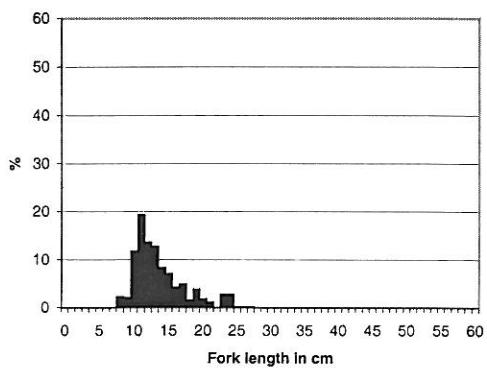

Brachydeuterus auritus
Mean length = 12.8 cm

Benin - Togo
N = 181

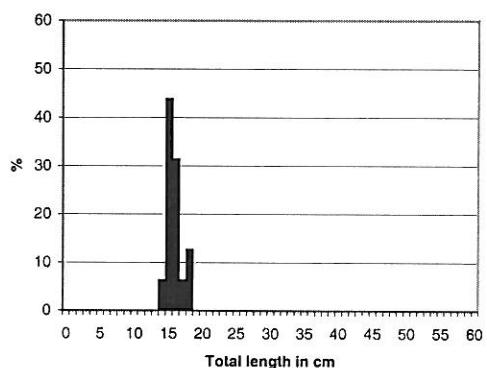

Pseudupeneus prayensis
Mean length = 13.5 cm

Benin - Togo
N = 41

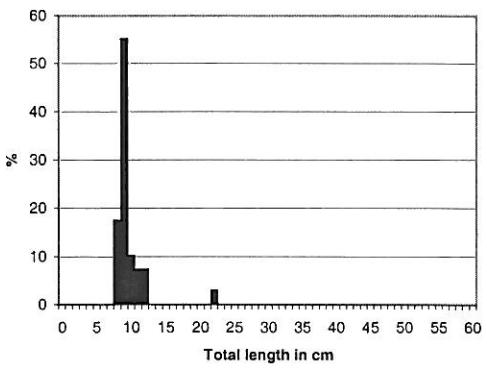

Galeoides decadactylus
Mean length = 14.2 cm

Benin - Togo
N = 119

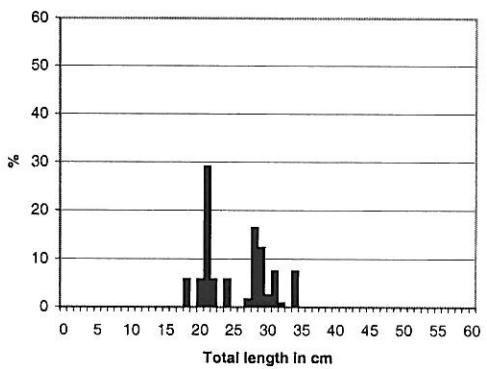

Sardinella aurita
Mean length = 16.2 cm

Benin - Togo
N = 16

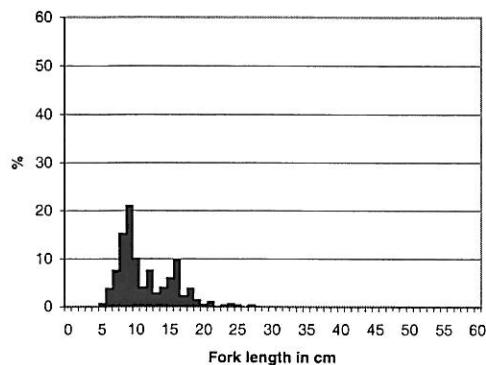

Sardinella maderensis
Mean length = 10.2 cm

Benin - Togo
N = 29

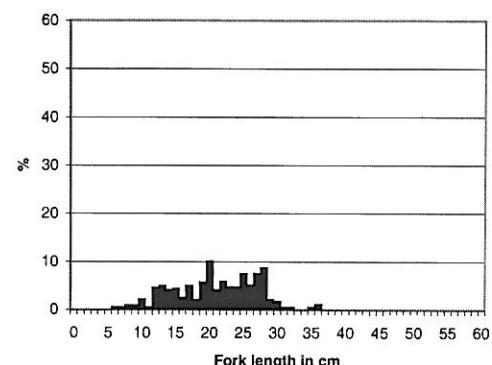

Selene dorsalis
Mean length = 25.7 cm

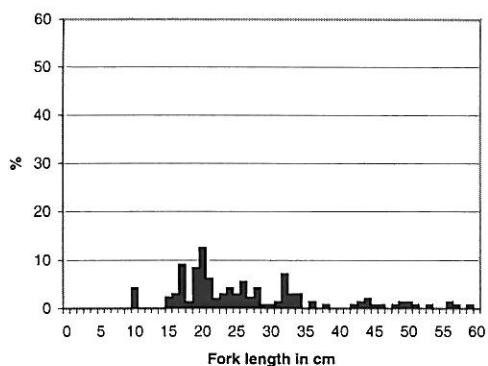

Benin - Togo
N = 32

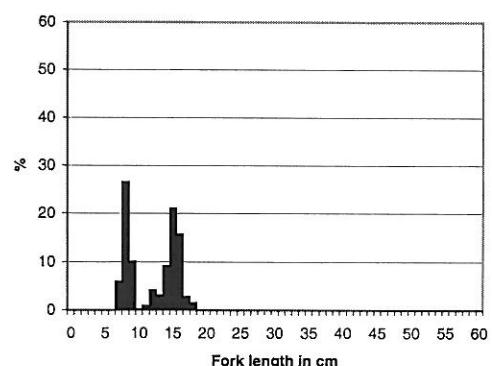

Pagellus bellottii Ghana
Mean length = 11.7 cm N = 329

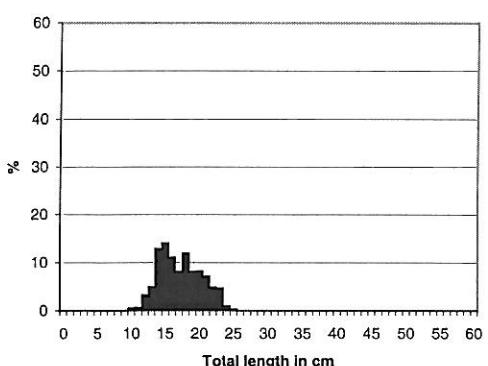

Pagrus caeruleostictus Ghana
Mean length = 21.5 cm N = 203

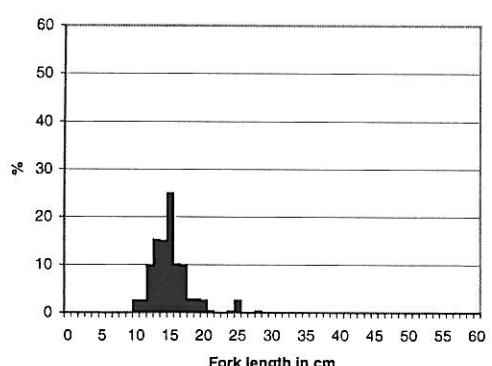

Dentex canariensis Ghana
Mean length = 26.8 cm N = 88

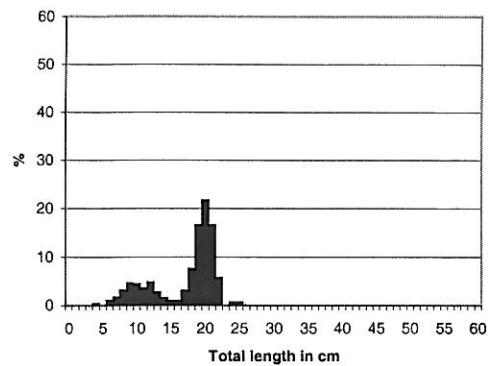

Brachydeuterus auritus Ghana
Mean length = 12.5 cm N = 273

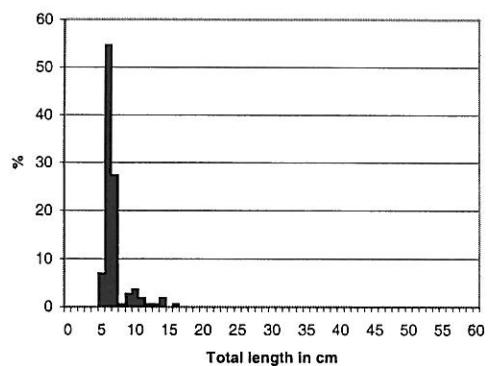

Pseudupeneus prayensis Ghana
Mean length = 17.7 cm N = 201

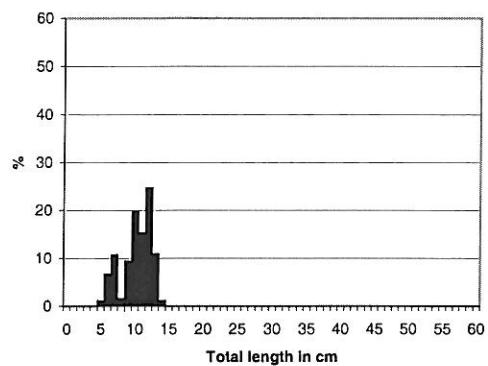

Galeoides decadactylus Ghana
Mean length = 15.5 cm N = 51

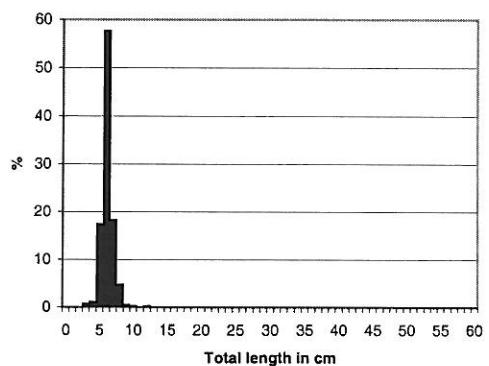

Sardinella aurita Ghana
Mean length = 17.7 cm N = 475

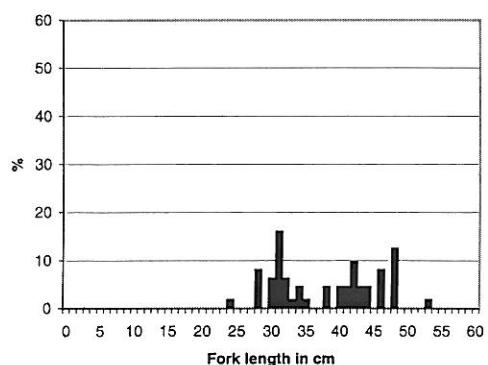

Sardinella maderensis Ghana
Mean length = 7.3 cm N = 39

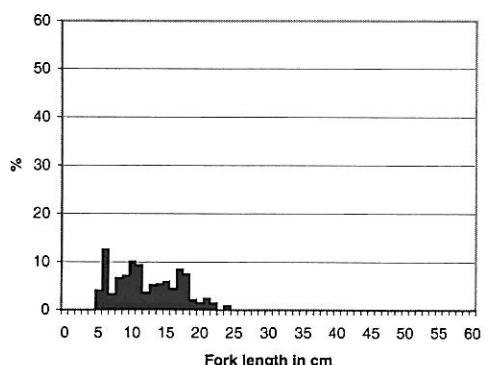

Ilisha africana Ghana
Mean length = 10.8 cm N = 83

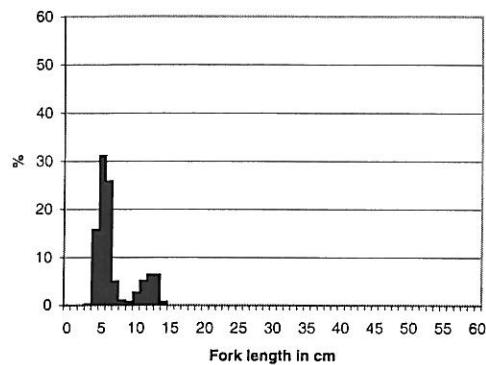

Engraulis encrasicolus Ghana
Mean length = 6.6 cm N = 463

Alectis alexandrinus Ghana
Mean length = 38.4 cm N = 29

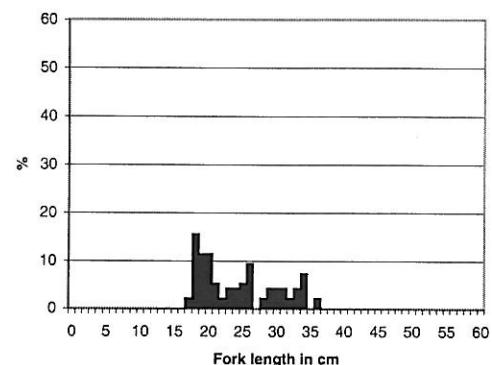

Chloroscombrus chrysurus Ghana
Mean length = 12.6 cm N = 412

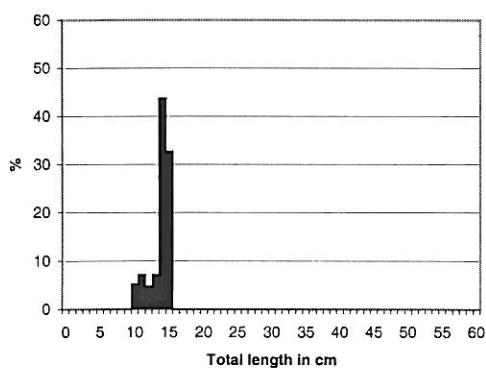

Decapterus macarellus
Mean length = 7.2 cm

Ghana
N = 233

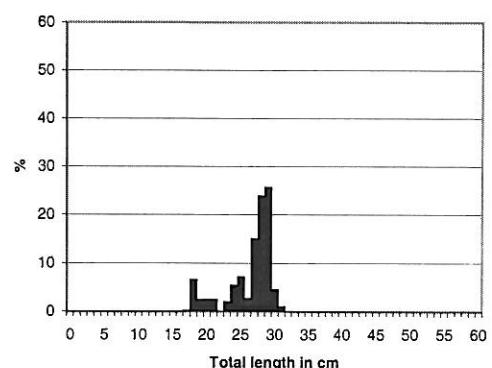

Selene dorsalis
Mean length = 24.7 cm

Ghana
N = 52

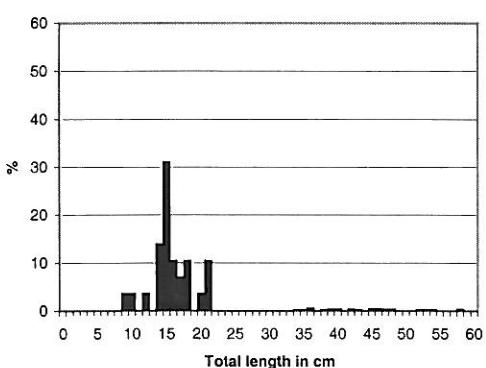

Trachurus trecae

Annex IV Instruments and fishing gear used

The Simrad EK-500/38kHz scientific sounder was used during the survey for fish abundance estimation. The Bergen Echo Integrator system (BEI) was used to scrutinize the acoustic records from the 38kHz echo sounder, and to allocate integrator values to fish species.

The details of the settings of the 38kHz echo sounder where as follows:

Tranceiver-1 menu (38 kHz lowering keel)

Transducer depth	5.50 m
Absorption coeff.	10 dB/km
Pulse length	medium (1ms)
Bandwidth	wide
Max power	2000 Watt
2-way beam angle	-21.0 dB
SV transducer gain	27.48 dB
TS transducer gain	27.72 dB
Angle sensitivity	21.9
3 dB beamwidth	6.8 dg
Alongship offset	-0.05 "
Athwardship offset	0.14 "

Range start	0
Bottom range	12 m
Bottom range start	10 m
Sv colour min	-67 dB
TVG	20 log R

Bottom detection menu Minimum level -45 dB

Fishing gear

The vessel has two different sized "Åkrahamn" pelagic trawls and one "Gisund super bottom trawl".

The bottom trawl has a headline of 31 m, footrope 47 m and 20 mm meshsize in the codend with an innernet of 10 mm meshsize. The estimated opening is 6 m (observed 5.7) and distance between wings during towing about 18 m. The sweeps are 40 m long. The trawl is equipped with a 12" rubber bobbins gear. The doors are of 'Thyborøn' combi type, 7.81 m², 1670 kg, their distance while trawling about 45 - 55 m in average, depending on the depth (least distance at low depths). This distance can be kept constant (about 50 m) at all depths by the use of a 9.5 m strap between the wires at 130 m distance from the doors (normally applied at depths greater than 80 m). On the present survey, however, the strap was not applied because most of the trawl hauls were made at bottom depths less than 60 m.

The SCANMAR system was used on all trawl hauls. This equipment consists of sensors, a hydrophone, a receiver, a display unit and a battery charger. Communication between sensors and ship is based on acoustic transmission. The doors are fitted with sensors to provide information on their distance and a height sensor is fitted to the bottom trawl to measure the trawl opening and provide information on clearance and bottom contact.

The pelagic trawl can be equipped with a trawleye that provides information on the trawl opening and the distance of the footrope to the bottom.
