CHAPTER 1 INTRODUCTION

1.1 Objectives

The cruise had the following overall objective:

- To work towards a representative quantitative bottom trawl sampling system for hake

Specific objectives were:

- To find the optimal vertical opening for a hake survey bottom trawl
- To establish the amount and type of hake passing over the trawl head rope
- To compare an 8 m opening commercial hake trawl to the 5 m “Nansen” trawl
- To quantify hake area densities from night echograms and night bottom trawl catches
- To relate hake area densities from these night experiments to hake area densities from day-time trawl catches in order to establish a catchability function for the sampling trawl

The first and second specific objectives were to be met by trawling with an echosounder looking upwards from the headrope of the trawl, and supplementing these data by doing pelagic hauls near the bottom with the multisampler, to collect samples from the different layers above the headrope.

The third specific objective was to be met by comparing a borrowed commercial high (8 m) opening hake net with the Nansen trawl.

The fourth and fifth specific objectives were to be addressed by acoustically surveying the trawl path during the night at slow speed generating high resolution echograms where individual fish traces could be counted in order to establish fish area densities. A night trawl catch described the amount of fish remaining on the bottom. The area densities generated

from echogram counts and the night time trawl catches then were to be compared to the daytime trawl catches in order to establish catchability values for the different trawl catches with the view to either estimate an average q, or establish a diurnal q function.

1.2 Participation

The scientific staff consisted of:

From Namibia:

 Titus ILENDE, Paul KAINGE, David KAMATI, Malakia SHIMANDA, Shaun WELLS

From South Africa:

 Chris SMITH

From Norway:

 Yngve FJELLSTAD, Ingvar HUSE, Magnar MJANGER, Jan Tore ØVREDAL

1.3 Narrative

The working areas are shown in Figure 1.

The vessel left Walvis Bay at 1800 h of 27 May and steamed south west. At S 24°25', E 13°40' at 320 m depth (Figure 1), good concentrations of cape hake and also some small deep water hake were found, and the work commenced here. The first trawl was shot at 0615 h in the morning, and the last was retrieved at sunset, around 1730 h. This area was worked for two days, after which the "Nansen" moved about 20 n. m. to the north west (Figure 1) to find greater depth (360 m) and more deep water hake. After two days here the ship had to return a sick technical assistant from NatMIRC to Walvis Bay, and a day was lost. On returning, an area further south, at position S 25°22', E13°44' (depth 330 m) was fished for two days after which operations were moved to S 25°34', E 13°41' at 390 m. After two days at this position also the course was set north to meet with "Welwitchia" west of Walvis Bay at S 22°40', E 12°20' at 330 m depth. Fishing continued here for two days also until "Welwitchia" arrived 7 June in the evening. The following day was spent rigging the commercial trawl and training the "Welwitchia" team in the use of the acoustic equipment they were to borrow for horse mackerel avoidance studies. 9 June was spent doing comparative fishing with the commercial trawl and the "Nansen" standard bottom trawl, as

well as trying to improve the “Nansen” auto trawl system. During the night the ship moved further south (Figure 1) to find hake with a pronounced vertical distribution, and continued the comparative fishing until the evening of 11 June when the course was set for Walvis Bay, arriving there early 12 June. The weather was basically favourable during the whole cruise, and no time was lost due to the weather conditions.

Figure 1. The work areas.

CHAPTER 2 HAKE SURVEY METHODOLOGY

2.1 Introduction

In Namibian hake bottom trawl surveys all catches are sampled for composition of weights and numbers by species. The bottom trawl has a headline of 31 m (float line), a footrope of 47 m, headline height of 5 m and a distance between the wings during towing of about 22 m. All trawl hauls are monitored by SCANMAR trawl sensors (headline height and distance between the doors). This technology allows the determination of the correct trawl bottom time. For conversion of catch rates to fish densities the area between the wings is assumed to be equal to the effective fishing area and the retention factor q is assumed to be equal to 1. This obviously is not correct, but as yet no data are readily available to estimate the catchability, the q is maintained at unity. The trawl doors are Thyborøen 7.9 m², and the trawl is a simple two panel Gisund Super. The length of a haul over bottom, recorded as distance trawled, is normally measured by log pulses from the GPS, and checked against the lengths of the traces of the hauls on the GPS plot on the MacSea system. Catch data are given in Annex I.

The swept area of a trawl haul is a crucial parameter in swept area survey methodology, particularly if the survey is supposed to estimate total biomass rather than just give a yearly index. Swept distance is easy to measure, while the sweeping width is the difficult parameter. In Namibian hake surveys a swept width of 18.5 m is used. If the assumption for hake is that wing spread is the correct sweeping width, we are in other words overestimating the hake population as the true wing spread is 22 m. Some attempts have been made to estimate a catchability factor for hake, but this is a general problem in swept area assessment methodology all over the world, and the methodological aspects are very complicated, as it is almost impossible to isolate each parameter involved. The problem consists of assessing how much fish of different species and size groups are herded towards the trawl opening by doors, sand clouds stirred up by the doors, and the bridles which attach the net to the doors, and which are about 50 m long. In addition there is also potential escapement over and under the trawl. No one has yet succeeded in assessing the true efficiency of a trawl gear except in very shallow waters. Still the swept area methodology seems to give the most consistent results for assessing demersal fish. Hake definitely seem to be less herded than e.g. cod in the experiments carried out so far, and the use of a slightly reduced (18.5 m) swept width in the assessment as opposed to the measured 22 m wing spread compensates for escapement over and under the trawl. Still this problem needs to be further addressed, and will be during this

cruise. A data material will be collected, consisting of night time echograms of hake. Most of the hake will be pelagically distributed at night, and can be counted as single fish traces from the echograms. In addition, night time trawl catches will reveal how much hake still remain on the bottom. The sum of trace counts and trawl catches will then represent the total density in the area. These values will be compared to the day-time trawl catches to hopefully reveal a set of catchability factors. These factors can then either be averaged to come up with a mean value q for the trawl, or modelled over the daytime period to provide a q which is modulated by time of day. The data will have to undergo a thorough analysis, and should preferably form the basis of a thesis.

The problem of mid-water occurrence of hake and its effect on the swept area assessments has been discussed in earlier cruise reports. Mesopelagic fish quite often cover the pelagic zone close to the bottom in the daytime, making it impossible to correct for pelagic hake. Consequently the hake biomass may be underestimated if no correction is made for situations where the pelagic hake distribution is unknown due to shading by mesopelagic fish and plankton. Probably this problem is most pronounced in the north where the acoustic correction to the trawl index constitutes an average of about 10 % addition to the demersal biomass in the day hauls where the conditions allow it to be assessed. It is, however, uncertain whether hake actually migrate into the dense mesopelagic fish shoals. This will be investigated by means of pelagic trawling during this cruise.

Carrying the aspect of midwater occurrence of hake further, the vertical opening of the sampling trawl is the main focal point of this year's methodology cruise. There are several questions to be asked:

-Do the present sampling trawl catches represent the true size and species composition of the stocks to be investigated?

-Are the present sampling trawls used high enough to adequately sample the major part of the vertical hake distribution throughout the day (including dusk and dawn), as well as on days with low illumination/high phytoplankton biomass?

-What is the abundance, size- and species composition of the hake passing over the headrope of the present sampling trawls?

-Can alternative trawl designs help in alleviating potential problems in this regard?

2.2 Methods and materials

The main instrumentation component used in this experiment was an upward looking echo sounder mounted on the trawl head rope. It consisted of a Simrad EY 500 echo sounder with a laptop PC mounted in an underwater unit built for at least 400 m of depth, mounted on the trawl top panel close to the mid of the head rope. Power was supplied from a separate underwater container mounted loose to the other container. The ES 3812 (38 kHz, 12°) transducer applied was mounted at the top mid of the head rope transmitting and receiving upwards towards the surface. The system was calibrated at 30 m bottom depth in Walvis Bay harbour 1 June.

The PC disk had the capacity to record sample data for 5-6 hours, well in excess of the 30 minute trawl hauls applied. The collected data were transferred to the “Dr. Fridtjof Nansen” network, normally after each trawl haul. The data files were subsequently transformed to EK 500 format and the files were post processed on the Bergen Echo Integrator system. Horizontal resolution applied was 0.1 n. m., while vertical resolution was 1 m.

Trawling took place between 320 and 390 m depth at four locations on the Namibian shelf (see Figure 1). Trawling was commenced at dawn (0615 h) and continued until dusk at around 1730 h. Two 30 minute 3 knot bottom tows were normally fished first, then a pelagic haul using the Multisampler. This devise attaches to the extension piece of the pelagic trawl and can take three separate fish samples with washing out intervals between each sample, within each trawl haul. The depth intervals fished were: from 5 to 20 m above bottom; from 15 to 30 m above bottom; from 25 to 40 m above bottom. After this haul another bottom trawl haul was fished, and then another pelagic haul, with a final bottom trawl haul if time allowed. Different depths and latitudes were fished to cover regional aspects as well as hake species and length distributions. The 300-400 m depth region was, however, focused upon as this is where the two resident hake species (*Merluccius capensis* and *M. paradoxus*) both are most abundant and have the most extended vertical distribution within the 400 m depth limitation of the echo sounder system, as well as being the depth range most frequently fished by the commercial fleet.

Weight/area densities from trawl catches were calculated using the mean length of the trawl catch, and the weight/length relationship of the form:

$$W = a * L^b$$

where W is weight, L is length, constant a was set to 0.007846 and 0.006543, and constant b was set to 2.9759 and 3.0425 for *M. paradoxus* and *M. capensis* respectively (Payne et al., 1987). The sweeping width used in calculating the swept area was 25 m as no constraining rope was applied, and the measured wing spread was 25 m. The towing distance was calculated using the GPS log.

Weight/area densities for acoustic observations from the trawl head rope were calculated using the relations:

$$n = s_A * A * 10^{5.7} * L^{-2}$$

where n is number of fish, s_A is integrator value, A is area and L is fish length. This relationship is derived from the standard target strength/length relationship with a constant of 68. For a unit area of one nautical mile square the A is unity, and the n becomes number of fish per square nautical mile. Weight/area densities were then calculated using the weight/length relationships described above.

Towards the end of the experiment a comparison between the “Nansen” sampling bottom trawl and a commercial high opening hake trawl was carried out. Drawings of the trawls are presented in Appendix II. The vertical opening of the “Nansen” bottom trawl is five metres, while the commercial trawl had a vertical opening of about eight metres. Both trawls were fished with door spread restriction consisting of a 10 m rope between the warps 130 m in front of the doors to ensure stable door and wing spreads, and to have the same sweep angles for both trawls. Both codends were lined with 25 mm mesh netting.. The door spread, wing spread and trawl height were monitored for both trawls with Scanmar net monitoring equipment. Tow time was 30 minutes as in the other experiments, and towing speed was still 3 knots.

Altogether 32 hauls with the echo sounder mounted were fished, in addition to 15 pelagic trawl hauls, each with three samples. An additional 14 bottom trawl hauls were fished to investigate the potential of the eight meter opening commercial trawl as a hake sampling trawl, 7 hauls with the “Nansen” trawl, and 7 with the commercial trawl. Finally, 8 night hauls were fished for the data material collected to find a catchability function for the trawl.

2.3 Results

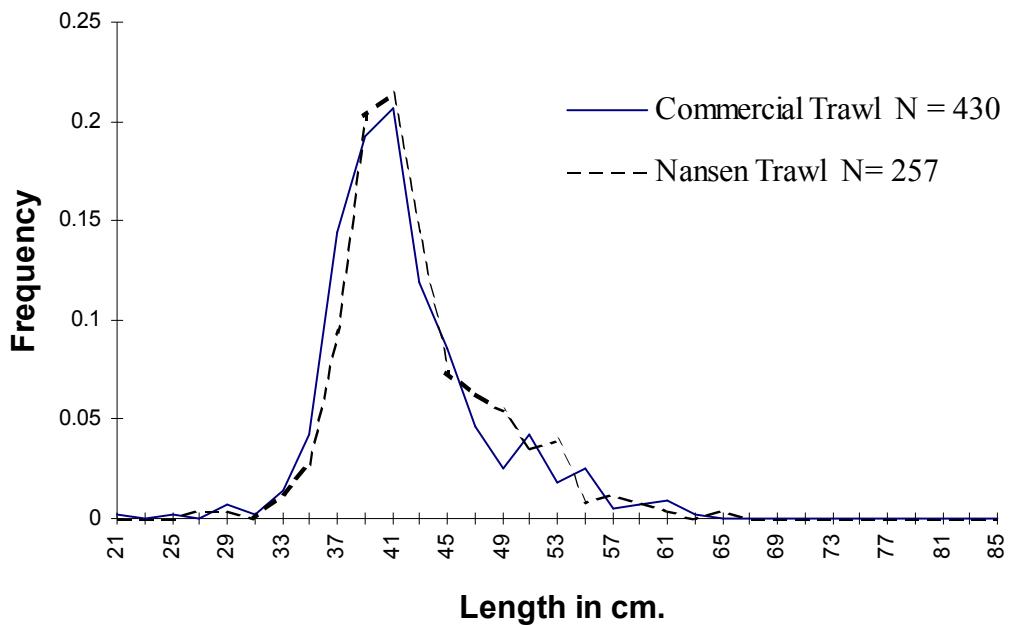

The area densities (kilograms per square nautical mile) calculated from trawl catches and head rope acoustics are presented in Figures 2 to 13, representing each of the five trawl lanes fished and the mean total. Catchability as a basis for the trawl based area densities was set to unity.

The species and length compositions of the headline acoustics and pelagic trawl catches are presented in Table 1.

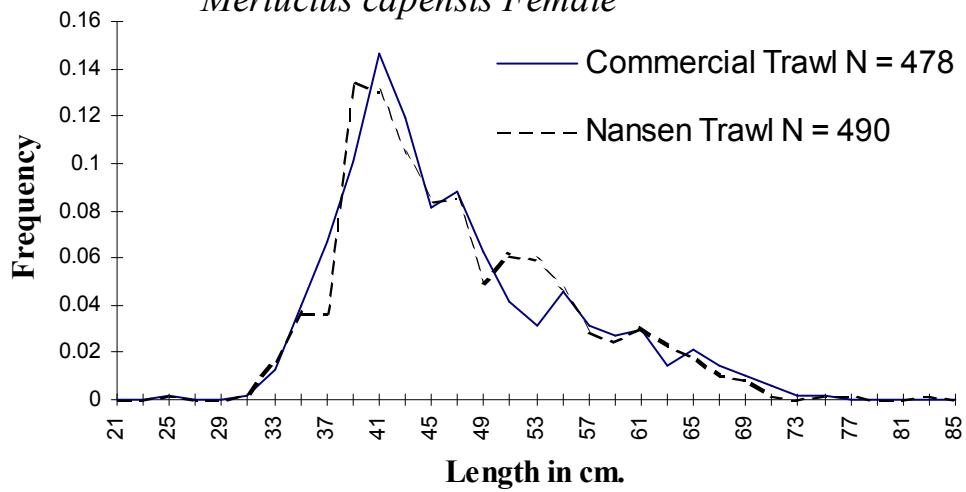

Table 1. Mean catches (kg^*h^{-1}) and mean lengths of hake species/sexes.

Bottom trawl catches	Mean lengths	Mean lengths	Mean lengths	Mean lengths	Mean lengths	Mean lengths	Mean catches
	Area 1	Area 2	Area 3	Area 4	Area 5	all areas	(kg/h)
M.cap.m	34.9	50.2	34.9	44.0	50.9	37.8	180.6
M.cap.f	45.8	55.4	37.1	48.8	52.5	44.7	337.7

Merluccius capensis Male

Merluccius capensis Female

Merluccius paradoxus Male

The trawl geometry results of the comparison experiment between the “Nansen” trawl and the high opening commercial trawl are given in Table 2.

Table 2. Net comparison trawl geometry data

	Door spread	Wing Spread	Trawl Height	*Sweep Length	Sweep Angle
Nansen Trawl	51,3 m	20,6 m	4,7 m	49	18,3°
Commercial Trawl	61,0 m	24,0 m	8,4 m	59	18,3°

* The backstrop length of 9 m included in the Sweep Length.

For the comparison experiment eight hauls were conducted with the commercial trawl and 6 with the “Nansen” trawl. The data for these trawls were standardised to units of fish density per square nautical mile for comparison purposes, and are presented in Table 3.

Table 3. Catch data (units of fish density in kg*nm⁻²) for the comparative fishing experiments between the “Nansen” trawl and the high opening commercial trawl.

	Nansen Trawl		Commercial Trawl	
	Catch kg	Mean Length	Catch kg	Mean Length
<i>M. capensis</i> male	13 050	42,7	10 557	42,0
<i>M. capensis</i> female	29 784	46,8	16 696	46,6
<i>M. paradoxus</i> male	676	30,1	3 357	32,6
<i>M. paradoxus</i> female	29 431	30,9	18 268	31,9
Total Hake	52 845		48 878	
Deepwater mix	15 065		13 322	
<i>T. capensis</i>	594	32,7	1 085	32,1
Total	68 504		63 285	

2.4 Discussion

The mean catch results indicate that the experiments were carried out in areas with a normal representation of the two hake species at this depth range on the Namibian shelf. The absence of *M. paradoxus* males both in pelagic and demersal hauls at all the five trawl localities is remarkable. Hake of this size are about to become sexually mature, and it is a mystery why there is a geographic sex segregation in young/juvenile fish like these. Another possibility is of course a skewed sex ratio, but this has not been reported, and is not very likely. The explanation of this sexual segregation is therefore not known, and should be investigated. The answer is likely to be found within the realm of maximisation of reproductive fitness.

The most prominent information to be had from the calculated area densities was that the bottom trawl based densities were much higher than the acoustically generated densities. This is of course also to be expected as hake are demersal fish, and are mainly harvested by

demersal trawls and long lines. Although, when looking at the cumulative area densities for the whole water column from the headrope and up as far as hake were found, the pelagic hake on average constituted one fourth of the total hake. Considering the vertical extent of pelagic hake in the acoustically generated area densities, these numbers are totally dependent on the post processing of the acoustic data. In the present experiment the upward vertical extent of hake probably was exaggerated. Former investigations of the vertical extent of hake (e. g. Huse et al, 1998) have shown that except for juveniles, the vertical extent seldom exceeds 60 m from the bottom, and during the day probably much less than that. This indicates that the present data probably should have been re-scrutinised, and that more extensive pelagic trawl hauls should have been carried out to fully elucidate this aspect. Pelagic hauls into very dense daytime concentrations of mesopelagic fish pressing against the bottom indicated that hake do not enter these layers, probably due to the sheer density of mesopelagic fish.

Considering the primary objective of the investigation, the optimal vertical opening of the hake survey trawl, the data indicate that little is gained by increasing the opening beyond the presently applied 5 m. This really has already been indicated, as e. g. in intercalibration exercises between "Africana" (1.5-2 m vertical opening) and "Nansen" only rather marginal differences have been identified. Remaining evidence that should be collected to facilitate a full evaluation of optimal vertical trawl opening pertains early morning and late afternoon hauls, and other situations of fishing where *in situ* illumination is low, causing hake to lift off the bottom. In such situations the catch of a higher trawl could potentially better represent the hake concentration. To make a definite difference the vertical opening then probably would have to be in the order of magnitude of 20 m. Rather than applying such a trawl, the vertical distribution of hake could be modelled as a function of *in situ* illumination, and this parameter could be measured or estimated during the cruises in order to compensate for vertical migration during situations of low *in situ* illumination.

The remaining consideration with regard to trawl vertical opening pertains the representativity of fish species and size in the catch. The trawl catches indicate that there is little or no difference in length from the bottom and up to 20-40 m for *M. capensis* males and *M. paradoxus* females. For *M. capensis* females the difference in mean length was about 5 cm, the larger on the bottom, while for *M. paradoxus* males the catches were too small to give any indication at all. This indicates that little or no special considerations pertaining species and size distributions may have to be made when compensating for pelagic distribution of hake in absolute abundance estimates.

The acoustic single fish data and night time trawl data collected to form the basis for a calculation of a catchability function for the trawl will be suggested used as a basis for a M. phil. Thesis for a Namibian student.

With the exception of *M. paradoxus* male, the “Nansen” trawl catches were consistently larger than that of the high opening commercial trawl. This could be the result of mesh selection taking place in the front part of the commercial trawl as the meshes in this part of the trawl were significantly larger than those of the “Nansen” trawl. This hypothesis was reinforced by the slightly larger mean length for both male and female *M. paradoxus*.

The length frequencies for both species of male and female followed the same trend with the exception of *M. paradoxus* male, but this was probably due to the small sample size

In the perspective of hake sampling trawl vertical opening, these data support the assumption that increasing the vertical opening will not readily and necessarily improve the representativity of the trawl samples obtained.

2.5 Conclusion

There is little evidence to indicate that a major benefit is to be had from increasing the headline height in excess of 5 m for a hake sampling bottom trawl.
