CHAPTER 1 INTRODUCTION

1.1 Background

Hydroacoustic surveying is a foremost means of estimating the abundance of pelagic fish, and is applied for a number of species worldwide. The main advantages of the method are the ability of sampling large volumes of water with relatively low effort and the high sample resolution in both the horizontal and the vertical planes. Acoustic surveying has the last decade been utilised in the direct assessment of the commercially important pelagic fish species of Namibia and Angola, specifically horse mackerel (*Trachurus trachurus capensis*, and *T. trecae*), sardinella (*Sardinella madarensis*, and *S. aurita*), anchovy (*Engraulis capensis*) and sardine (*Sardinops sagax*). The method relies, however, on the fundamental assumptions that 1) unbiased returns from all targets are recorded, 2) that the recorded acoustic intensity can be correctly allocated among the taxons present, and 3) that the acoustic intensities of each taxon can be correctly converted to actual animal densities.

Assumption 1 may, however, be violated under the following conditions:

- a) If targets inhabit volumes not covered by the acoustic beam, i.e. if they occupy the acoustic blind zones, at the time of sampling. Specifically, if these are in the near-bottom dead zone, in which targets are masked by the first bottom returns, and the upper blind zone, or between the surface and the upper integration limit of the transducer (transducer near field + the narrowest part of the beam). This is a problem in species that are distributed close to the bottom (e.g. horse mackerel) or the surface (sardinella) during surveying.
- b) If the recorded back-scattering area s_A (m^2/nm^2) of scatters is affected by the presence of the vessel, i.e. avoidance behaviour. Vessel avoidance may cause fish to move out of the acoustic beam, in which case they are not recorded, or to change their angular orientation within the beam (i.e. to dive), and hence their scattering properties. Bias in acoustic abundance estimates due to vessel avoidance is reported for a range of pelagic fish species.
- c) Attenuation of the acoustic pulse due to absorption in scattering layers may cause a range- and density dependent non- linear reduction in recorded density for strong aggregations.

Assumption 2 entails that the different taxons of the ensonified population can be recognised. Targets are usually identified by combining visual scrutiny of the scattering patterns with data from independent trawl samples from the ensonified population, but problems are frequently

encountered due to e.g:

- a) Spatial and/or temporal changes in scattering properties of taxons due to changes in behaviour (e.g. schooling/shoaling, dispersing, vertical migration),
- b) Overlapping distributions, masking acoustic characteristics of different targets (e.g. horse mackerel mixed with aggregations of prey items like euphausiids and/or copepods).

Representative biological samples are prerequisite also for obtaining mean size and mean weight estimates needed to convert acoustic density to total number of individuals and to total biomass, respectively. For splitting the biomass on size groups, size distribution and size-weight keys are required as well. Commonly used in acoustic surveying for this purpose are sampling trawls that are specially designed to catch representatively. There are, however, certain limitations related to trawl performance, mainly:

- c) Availability – the extent to which the targets were present in the sampled volume (trawl sample volume is always very small compared to the acoustic sample volume),
- d) Catchability – the extent to which the targets encountered in the trawl path are caught (usually both size- and species dependent),
- e) Compatibility – the extent to which the acoustically and biologically sampled volumes can be compared (knowledge of trawl position, depth and geometry, and contamination of biological sample from other depths).

Finally, the calculation of absolute fish densities requires that the dorsal aspect scattering of the targets at the given frequency can be predicted. The mean backscattering cross section of a target σ_{target} (m^2) is commonly related to the size of a standard sphere with a 2 m radius, giving the relation (Love 1971):

$$\text{TS} = 10 \log (\sigma_{\text{target}} / 4\pi) \quad (\text{dB}) \quad (1)$$

where TS is the target strength, or the backscattering cross section in the logarithmic domain. The target strength is usually related to the fish total length (L), using the relation (Foote et al. 1986):

$$\text{TS} = x \log L + y \quad (\text{dB}) \quad (2)$$

where x and y are linear regression coefficients. For many commercially important species σ has been shown to be proportional to the squared total length of the fish at 38 kHz. For

facilitation of direct comparison between different regressions series, (2) can thus be modified to a one-coefficient form, keeping $x = 20$ (Love 1977):

$$TS = 20 \log L + b_{20} \text{ (dB)} \quad (3)$$

If the average acoustic backscattering cross section $\langle\sigma\rangle$ of the ensonified population is known, recorded area backscattering coefficient, s_A (m^2/nm^2) can hence be converted to number of fish per unit squared nautical mile, ρ_A using:

$$\rho_A = s_A / \sigma \quad (4)$$

The absolute acoustic estimate relies not only on the unbiased estimate of the integrated backscattering area of the target population, but also on the mean size of the targets, the relationship between target size and target strength, and (unless the target strength is related directly to weight) the relationship between size and weight.

Errors in acoustic surveying relevant for the BENEFIT region were discussed during a workshop in Cape Town in December 2000. Several of the key factors above were discussed, and the workshop provided advice for activities to be addressed during this survey.

1.2 Objectives of the survey

The overall survey objective was to carry out experimental work that may aid in reducing errors in hydroacoustic surveys in the BENEFIT region. The main objectives were:

- To conduct calibrated acoustic measurements of Cape horse mackerel (*T. trachurus capensis*), Cunene horse mackerel (*T. trecae*), Round sardinella (*Sardinella aurita*) and Flat sardinella (*S. maderensis*) at 18, 38, 120 and 200 kHz.
- To study diurnal variations in recorded acoustic density, s_A (m^2/nm^2) and target strength, TS in horse mackerel.
- To record *in situ* target strength on loosely organised, monospecific aggregations of homogeneously sized pelagic fish.
- To study avoidance behaviour of pelagic fish during acoustic surveying, and to quantify effects of vessel avoidance on recorded acoustic densities.

- Species identification of layers and schools of fish using the mid-sized pelagic sample trawl (~15 m vertical opening) fitted with Multisampler, surface trawling (“balloon hauls”) using the small pelagic trawl (~10 m opening) and bottom trawls (~5 m).
- Species identification of scattering layers of plankton using the Hydrobios multinet plankton sampler.
- Logging of meteorological data (air and sea surface temperature, wind strength and direction), CTD casts (temperature, salinity, Oxygen) and ADCP profiles (horizontal and vertical current and error speed and direction).

1.3 Participation

The scientific staff consisted of:

From IIM: Filomena VAZ-VELHO¹, Henriette Lutuba NSILULU¹

From NatMIRC: Angie KANANDJEMBO¹, Jens-Otto KRAKSTAD¹, Josia HALWOODI², Aili HAMUNYELA², Erin RUSH³, Martha UUMATI²

From IMR: Bjørn Erik AXELSEN¹ (Cruise leader), Reidar JOHANNESEN¹, Magnar MJANGER¹, Magne OLSEN¹.

2. 22.04 - 02.05 2001
3. 18.04 – 22.04 2001

1.4 Narrative

The R.V. *Dr. Fridtjof Nansen* departed from Walvis Bay at 14:00 (local time) on 18th April 2001, and headed directly for Lang Strand for calibration of the 18, 38, 120 and 200 kHz scientific echo sounders.

The vessel steamed north to Cape Frio at 19°00'S after completion of the calibration on the 20th April. Two consecutive 24-hour diel cycle stations were carried out from 18:00 on 21st April. Hydroacoustic data was recorded continuously from all four frequencies of the EK500 during the experiment. The first pelagic trawl started at 19:00 and the last pelagic multisampler trawl

of the experiment ended at 18:30 on the 23rd. 13 complete sampling cycles including multisampler trawls, CTD/ADCP casts and multinet plankton hauls were completed during these experiments.

The R.V. Welwitschia met R.V. Dr. Fridtjof Nansen midday on 22nd April during the experiment for a changeover of personnel.

After completion of the first diel cycle experiment the ship steamed northwards to Tiger Bay in Angola where the portable transducer for the Simrad EY500 echo sounder mounted in the small (5.3 m) Man Over Board (MOB) boat was calibrated. The vessel then searched for dense concentrations of horse mackerel and sardinella further north into the Namib area. The second diel experiment was initiated here at 01:00 the 27th April. Two 24 hours cycles were completed on the 29th April 00:00. Hydroacoustic data was recorded continuously from all four frequencies of the EK500 during the experiment, and altogether 12 cycles of multisampler trawls, bottom trawl, CTD/ADCP and multinet hauls were conducted.

The next experiment was a mini survey conducted north of Lobito. Three cycles of avoidance studies on Sardinella were conducted from 12:00 on the 29th April to the 1st May using the MOB boat in cooperation with the Dr. Fridtjof Nansen. Both vessels recorded acoustic data continuously during the experiment. The vessel then steamed to Luanda where it arrived the 2nd May at 08:00.

CHAPTER 2 METHODS

2.1 Hydrography and weather data

Meteorological information such as air and surface temperature, wind speed and direction and solar intensity was logged continuously from the ANDREAA weather station. CTD casts from the Seabird 911 CTD were done regularly to obtain profiles of temperature, salinity and oxygen. Samples for calibration of the oxygen and salinity sensors were also collected and analysed onboard. Current measurements using a 150 kHz RDI ADCP (Acoustic Doppler Current Profiler) measurements were carried out at each CTD station.

2.2 Survey area

The survey area was the shelf from Walvis Bay, Namibia to Luanda, Angola (Figure1). The first diel cycle experiment took place in northern Namibia at 19°01'S 12°04'E, at approximately 180 m depth. In this experiment the same 5 nm section of track was sampled repeatedly for 48 hours. The second diel cycle experiment was conducted outside Lobito, Angola at 12°28'S 13°25'E for another 48 hours. The water depth was approximately 50-70 m. Two successful mini survey experiments were carried out north of Lobito at 12°09'S 13°39'E using the MOB boat.

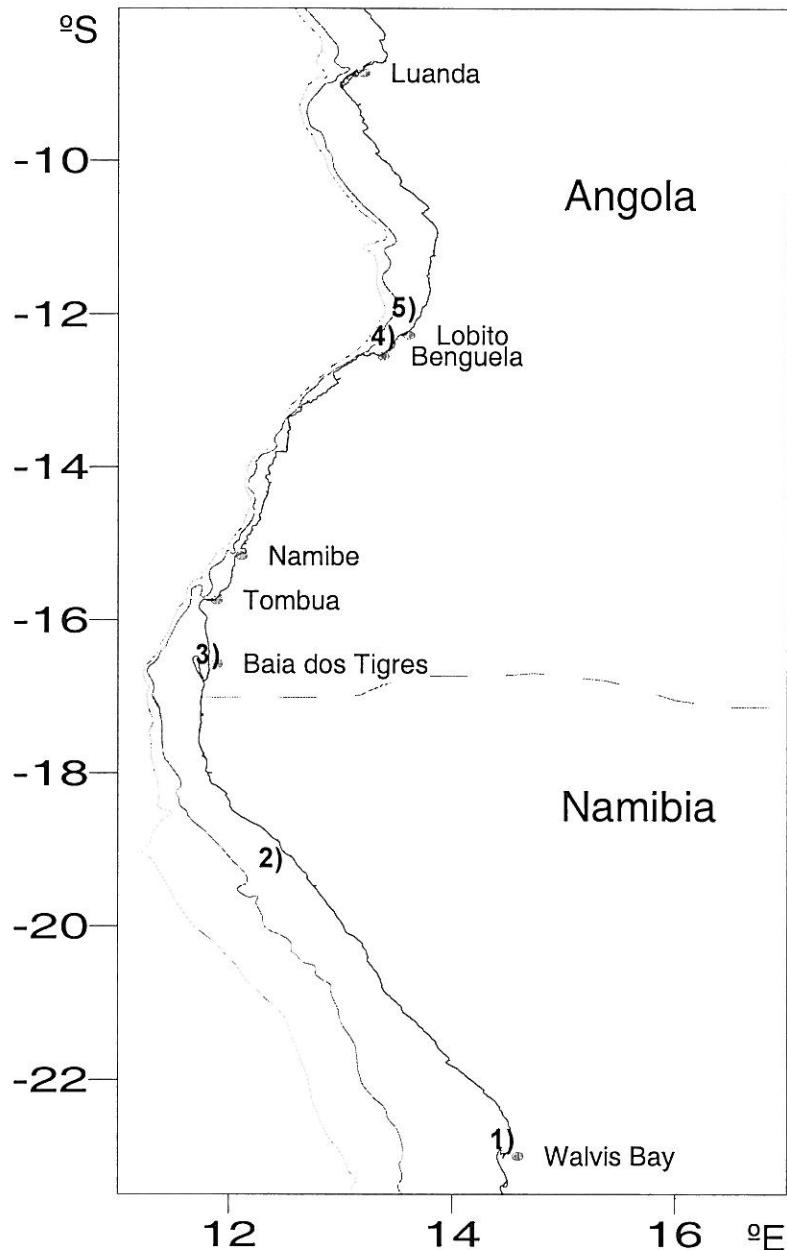

Figure 1. Survey area with the different working areas: 1) Calibration of EK500 18, 38, 120 (EK1) and 200 (EK2) kHz echosounders; 2) 48h diel cycle 1; 3) calibration of portable EY500 38 kHz echosounder on the MOB boat; 4) 48h diel cycle 2; 5) Mini-survey for comparative avoidance experiments.

2.3 Multi-frequency acoustic sampling

Two Simrad EK500 echo sounders equipped with a total of four acoustic transducers mounted on the submersible keel (Figure 2) operating at nominal frequencies of 18, 38, 120 kHz split beam and 200 kHz single beam were operated throughout the survey. The settings used in the two EK500 transceiver menus are presented in ANNEX I. To minimise differences in sampling resolution, the pulse length and bandwidth setting of the four transducers were altered to short/wide (18 kHz) and long/narrow (38, 120 and 200 kHz) respectively. Sonardata Echolog® software version 2.1 was used to log the data from the Ethernet communications port. Data

were also logged simultaneously using the Bergen Echo Integrator (BEI). Analysis and post processing of logged data was done using Sonardata Echoview® software version 2.20.52. All four transceivers were successfully calibrated in Walvis Bay (ANNEX II) and the new settings were implemented before the start of the survey.

2.3.1 Refit of drop keel in Cape Town, January 2001

Recently, several modifications have been made to the transducer arrangement of the drop keel. The modifications were done during a refit in Cape Town in January 2001. The ship was dry-docked, and the keel was lifted up through a shaft that runs in the full height of the ship and opens up onto the roof of the wheelhouse. The keel was transported to a workshop where the keel-face was levelled according the off-axis deviation angle at normal ship trim, as estimated during acoustic surveys. The keel was sandblasted, primed and painted. Shells, barnacles and other shrubbery were removed from the keel and inside the shaft. A new, bigger cable gate was fitted to the shaft in order for all cables to run through the same gate. The cables for the 38 and 120 kHz transducers, and the Scanmar hydrophone (HCL) were somewhat squeezed, and were therefore replaced with new, thinner, cables (50 m).

New holes were bored for 18 kHz (aft), 120 kHz (central, starboard side) and 200 kHz (central, port) transducers. The 38 kHz was left in its original position. The old hole for the 120 kHz was covered. The existing 18 kHz transducer was removed from its initial position on the hull and fitted onto the keel. A new 200 kHz single beam transducer (ES 200-7F) was fitted next to the 120 kHz split beam transducer in the centre of the keel face. The modifications of the transducer arrangement have effectively ensured optimal configuration of the transducers, as they are now positioned on the same acoustic axis giving ~vertical transmission at normal ship trim and with minimal horizontal spacing of the transducers. The new transducer arrangement on the drop keel is illustrated in Figure 2a, while Figures 2b and 2c are photos of the keel face before and after the refit, respectively.

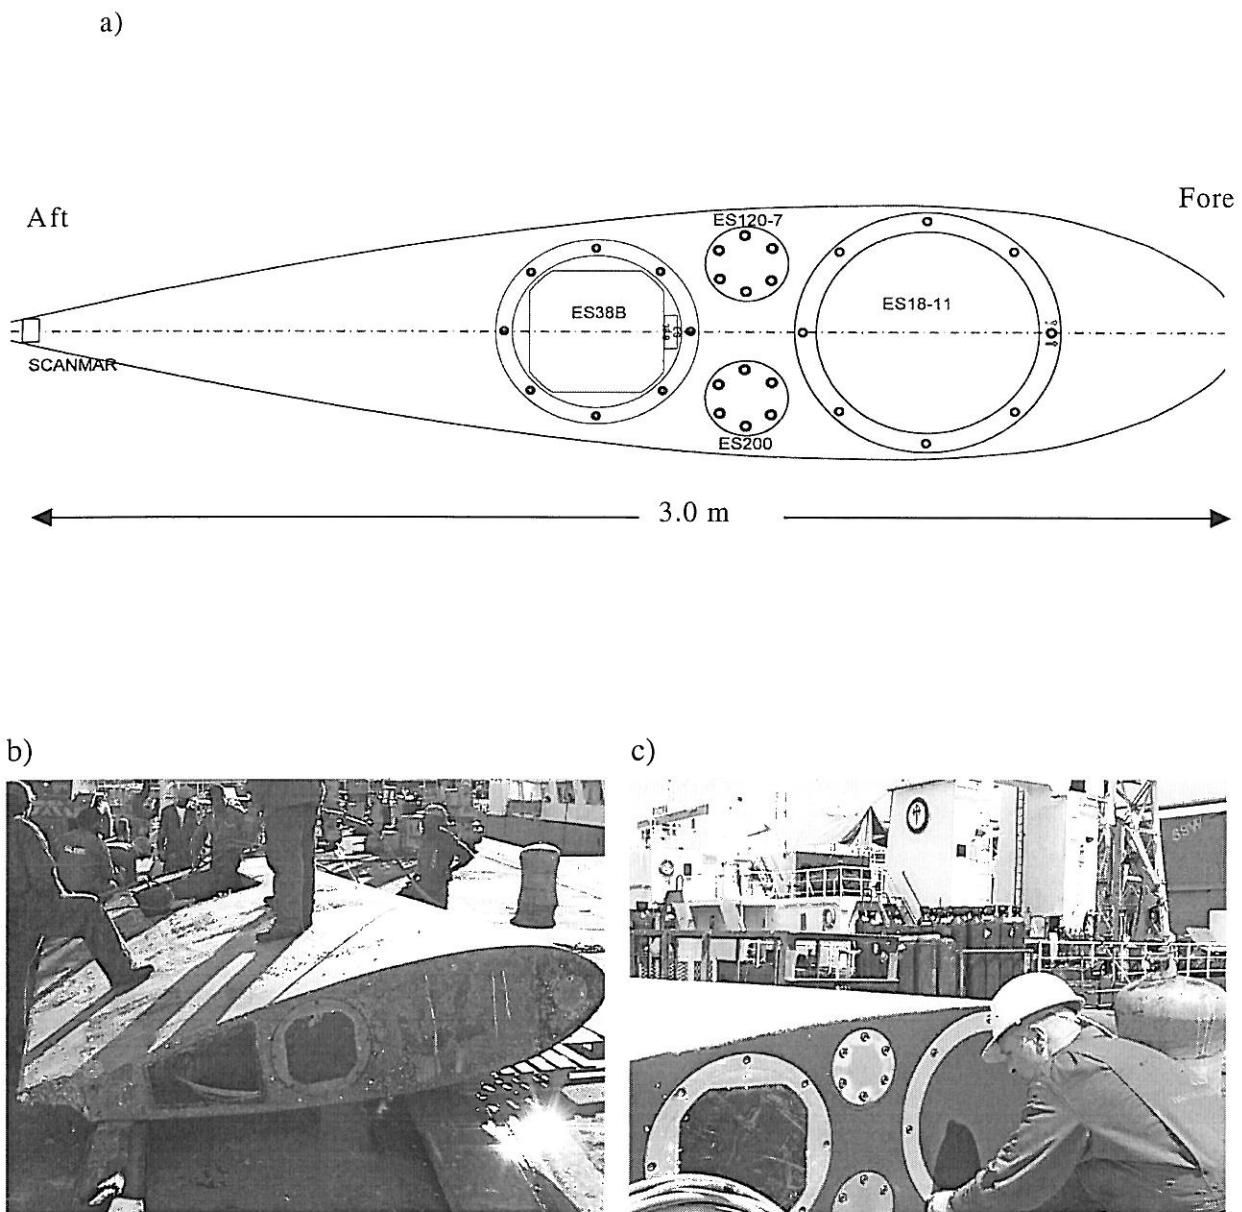

Figure 2. Transducer arrangement of the drop keel of R/V "Dr. Fridtjof Nansen" showing schematic illustration of the new orientation of the transducers on the keel (scale 1:10) (a) and photo taken before (b) and after (c) the refit in Cape Town in January 2001.

2.4 Trawl sampling

Sampling trawls used included the large pelagic trawl (30 m vertical opening) with the multisampler attached, the small pelagic trawl (10 m vertical opening) and a bottom trawl (5 m vertical opening). The multisampler was equipped with three codends, which were remotely opened and closed to obtain discrete, uncontaminated samples at different depths or to sample single schools. Thyborøn' Kombi 6.7 m² 1670 kg trawl doors were used in all hauls.

Random samples of fish representative of the total catch were taken from the trawl catches. The size of the samples was largely determined from the degree of mixing of the catch. In cases where the catch was small, the total catch was always sampled. The number and total weight for each species were recorded in each sample and raised to the total catch. A random sample of about 100 fish per species of sardinella and horse mackerel, if available, were measured to the nearest 1 cm below total length to obtain the size composition of the catch. Biological samples of the two horse mackerel species including individual length, weight, sex, maturity and stomach fullness were recorded. Stomach samples of *T. trachurus capensis* and *T. trecae* were collected for further analyses onshore.

A total of 87 trawls were completed during the survey. Altogether 64 hauls were multisampler trawls, and a further 7 trawls were conducted with the small pelagic trawl (mostly with floats on the headline). Bottom trawls done during the second diel cycle experiments made up another 16 trawls. All catches were sorted for species composition and entered into the NAN-SIS trawl database. A summary of all catch rates is shown in ANNEX III.

2.5 Diel cycle experiments

For identification of different scattering layers, and examination of structural patterns and trophic relations two diel cycle experiments were completed, one in the Northern Benguela and one in the Angola dome area. Both experiments lasted 48 hours and sampling was restricted to the same 5 nm section of track. The area under the vessel was continuously monitored with multifrequency acoustics. The different scattering layers were continuously sampled in cycles (ANNEX IV). A cycle commenced with the pelagic multisampler trawl followed by a bottom trawl (only experiment two), and depth discrete samples of plankton and nekton with the Hydribios multinet sampler, followed by a CTD cast and ADCP to the bottom.

The hydribios sampler was fitted with five 405 µm mesh nets and flowmeters at the front of each net monitored the volume of water filtered by each net. The nets were hauled obliquely at 0.5 m.s⁻¹ while steaming at less than 2 knots towing speed. The concentrated samples were preserved in 4 % buffered formalin. Hydrographical sampling was carried out after each cycle. CTD casts obtained profiles of water temperature, salinity and dissolved oxygen. Water samples were collected for calibration of the oxygen probe (the salinity probe was delivered for service on land before the survey). Depth specific current speed and direction, including the vertical component and error were measured continuously throughout the experiments using an Acoustic Doppler Current Profiler (ADCP). A total of 14 cycles were completed during the first experiment and 13 cycles during the second experiment, altogether constituting a total of 13 bottom trawl samples, 57 multisampler trawl samples, 125 Hydribios Multinet plankton

samples and 27 CTD casts.

Acoustic data at all four frequencies was logged continuously to determine the depths of and to integrate the various pelagic scattering layers. Trawls determined the species composition of the layers and the size frequency of the main species was measured. A sub sample of each species of horse mackerel were collected for analyses of stomach fullness and stored for stomach content analyses ashore.

2.6 *in situ* Target strength experiments

During diel cycle 1 (northern Namibia), the scattering of a population of juvenile horse mackerel around 15 cm (14.9 ± 0.71 cm (Mean \pm Std. Dev., N = 2010) was monitored. The min-max range of total fish length was 12-19 cm. The small sample variation in fish length makes the population suitable for target strength considerations. The population was readily identified during vertical migrations from about 50 m (25 to 75 m) at night to about 125 m (100-150 m) during daytime. Some undulations in the layers were seen both during day and night time, and the degree of polarisation changed over time, particularly at daytime. The bottom depth in the area was about 175 m.

The echograms from the acoustic recordings during the experiment was combined with information from the biological sampling (plankton multinet and cod end multisampler) by superimpose on the echograms “marker” boxes at relevant depths and time locations in Echoview. The different scattering layers were identified and the main taxons and their relative abundance in dry weight were noted in the “comment” fields for scrutiny purposes. The data were then divided according to the sample activities that had been carried out (i.e. trawling, plankton netting, CTD casts etc.). Relatively loose aggregations of horse mackerel were carefully selected for extraction of traces for target strength considerations. Only parts were scattering layers of plankton (krill and euphausiids) did not appear to bias the scattering from the horse mackerel, were used in the analysis. Only single target outputs from the TS detection algorithm of the EK500 (single target telegrams) were used. These had to be validated for erroneous contributions from plankton and multiple records of target fish. Single targets were extracted using the target-tracking module of Echoview (v 2.20.52, released 2001). This module identifies traces originating from single specimens by comparing the position of scatterers from ping to ping. Traces were accepted according to predefined criteria (Table 1). Criteria should be formulated to exclude multiple targets and other invalid contributions, but should not be so strict that unreasonably many valid targets are likely to be excluded. Trace-data (mean trace target strength, number of records in trace, mean depth, time etc) for approved regions was then exported to CSV-files for further processing. Tracking the targets is

advantageous because it promotes equal contribution of all ensonified fish, as only mean-track values are re-averaged to obtain population means. All averaging must be done in the linear domain.

At a later stage these data will be further scrutinised using multi-frequency analysis techniques. Two approaches will be pursued:

- 1) Removal of contributions from other scatterers (krill and euphausids) using multi-frequency target identification.
- 2) Removal of multiples using split-beam target triangulation

For certain taxons, the frequency response (differences in target strength between frequencies) is known for applied frequencies. Masking away contributions from non-target scatterers (that satisfy known frequency responses unique to these groups) may hence aid to remove “noise” from the target strength records (approach 1). Further, contributions from multiple targets can be considerably reduced using the split-beam target triangulation method, in which recorded targets in the acoustic beam of interest (e.g. 38 kHz) are validated by means of cross-referencing their positions with those of the other split-beam transducers (18 and/or 120 kHz) (approach 2). Other than removing biased data points and making interpretation easier, these techniques, if successfully applied, enable the use of a larger part of the original dataset, hence increasing the value of the observations.

Table 1. Acoustic settings in the target-tracking module of Echoview when exporting single targets for TS-measurements

EV-file properties Menu (Track settings)		Variable settings (Data settings / filter properties)
Min. numbers of single targets in a track	6	Filter angles
Max. gap between single targets (pings)	1	Max. allowed alongship angle (\pm degree)
Max. change in range (m)	0.5	Max. allowed atwartsship angle (\pm degree)
Max change in alongship angle (\pm degree)	4	Max gaine compensation (dB)
Max change in atwartsship angle (\pm degree)	4	

2.7 Vessel avoidance experiments

Four mini-survey experiments were conducted north of Lobito using the MOB boat (5.3 m long, 50 HP outboard engine) equipped with a portable 38 kHz scientific echosounder (Simrad EY500) in order to study near-surface schooling and vessel avoidance.

The first experiment was carried out midday 29 March, while the second started on the 30th in the morning. A nighttime experiment later on that evening had to be terminated after the laptop

used to log the acoustic data on the MOB boat was soaked by seawater. A new coverage was carried out the next morning. Unfortunately, due to data logging problems, only data from two complete replicas of the mini-survey were obtained.

During the experiments, the small boat was operated at a distance of about 0.4 nm ahead of the Nansen at a speed of approximately 5 knots (Figure 3). The operation of the MOB boat was assisted via radio communication (portable VHF), using distance and bearing information of the MOB obtained from the radar on the Nansen. Assuming that the MOB boat did not exhibit any avoidance responses in the fish, this can be considered comparative calibrated acoustic records of the non-disturbed and the regular survey situations. It should be noted, however, that the standard speed during surveys is 10 knots, and that the avoidance pattern may then be different.

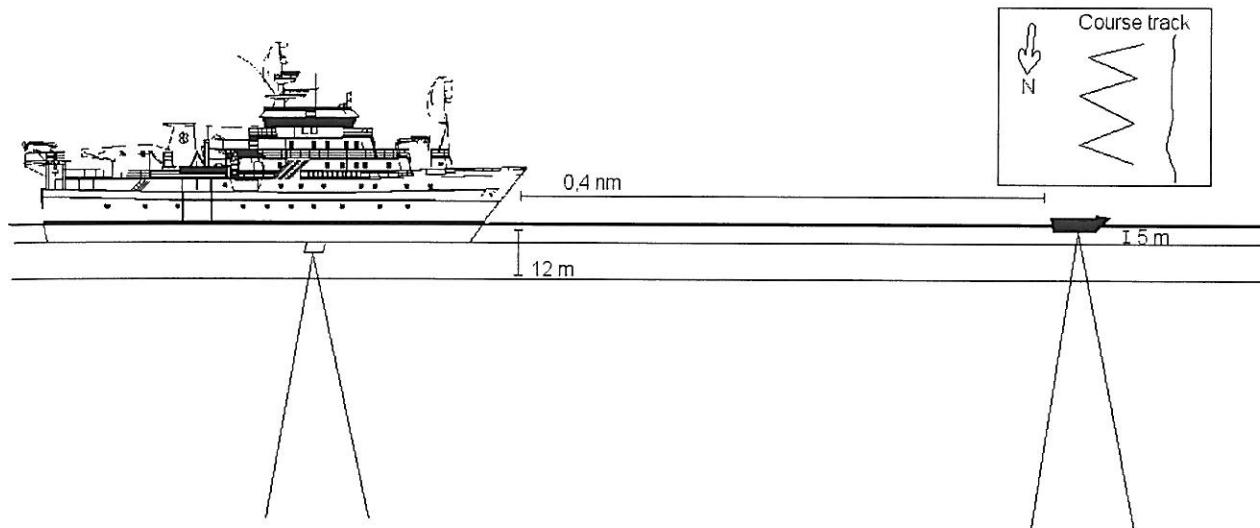

Figure 3. Illustration of the vessel avoidance experiment with Dr. Fridtjof Nansen and the MOB boat

CHAPTER 3 RESULTS

The project collected large amounts of zooplankton, hydro acoustic, ADCP data that requires massive analyses after the survey. This report can therefore only show examples and preliminary results from the survey. However, the main objectives of the survey stated in the introduction and suggested during the survey error workshop in December 2000 have been accomplished. The results will be analyzed in forthcoming workshops under this BENEFIT project and the final results discussed in publications derived from these results.

3.1 Hydrography and weather data

Conditions during the survey were mostly favourable with light northwesterly winds throughout the duration of the survey. Hydrographical profiles for the CTD cast from both diel stations are presented in Figure 4 (a and b) and for the MOB mini survey. The data show relatively stable oceanographic conditions during both experiments with some diurnal variation during diel cycle two especially in the oxygen profile. ADCP data collected during the diel cycle experiments will be processed in Bergen at a later stage.

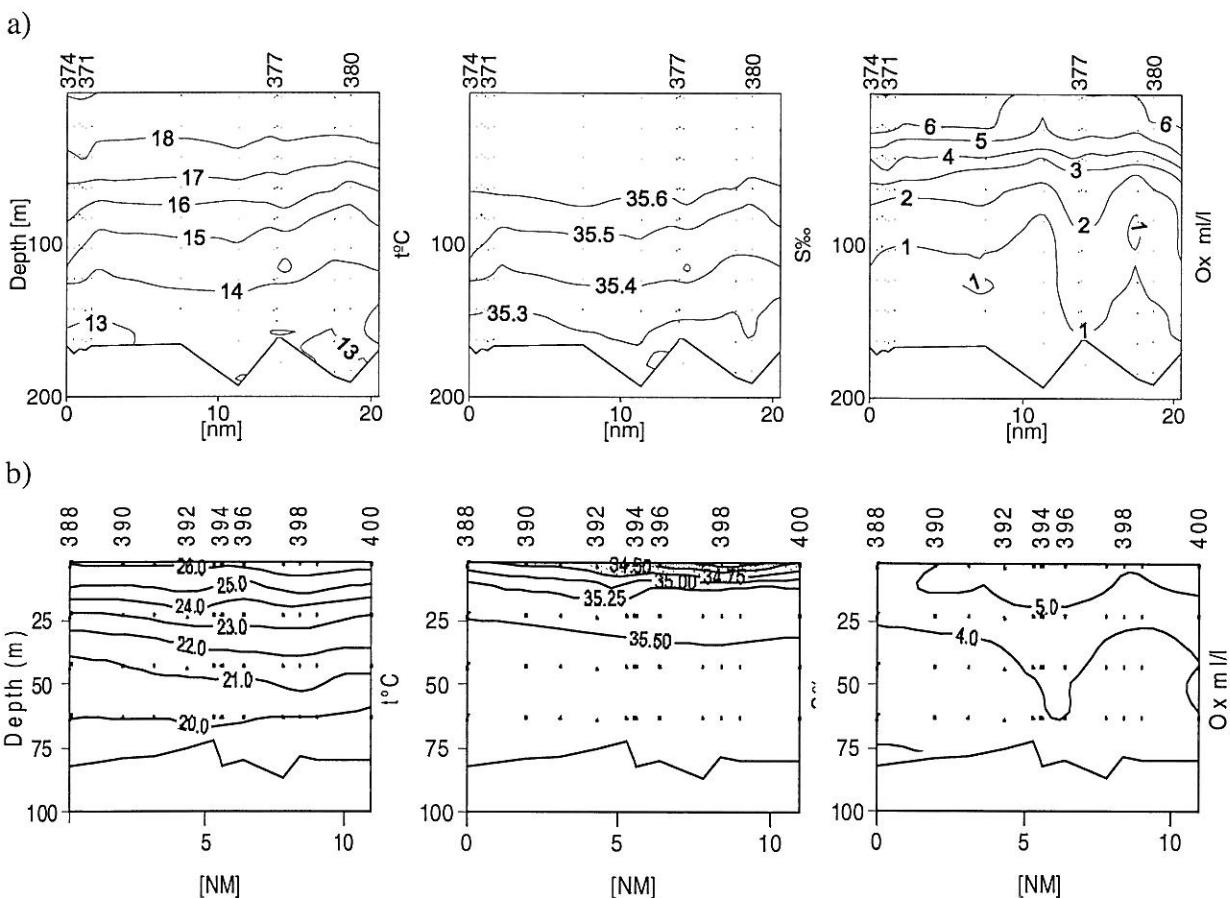

Figure 4. Temperature, salinity and oxygen profiles from diel cycle experiment 1 a) and 2 b)

3.2 Diel cycle experiments

Analyses of species and size composition in the multisampler trawl nets from diel cycle one and two were done at sea to identify the different scattering layers. Stomach content and plankton multinet were taken back and will be analysed on land.

3.3.1 Diel cycle I

A composite plot of the acoustic recordings from the 38 kHz transducer during the first diel experiment is shown in Figure 5. The species composition during the first 48 hours cycle was dominated completely by juvenile cape horse mackerel with a homogenous length distribution of 14.9 cm (Figure 6). Some jellyfish (*Aequorea aequorea*) were present on all depths. The zooplankton in the water column will be identified from the plankton multinet hauls. The horse mackerel had a clear diel vertical migration, with highest concentrations in the upper 50 m at night and aggregated in midwater deeper than 100 m during the day. The vertical migration was gradual, and the fish were found at the deepest water depths around midday. The bottom depths during the experiment ranged between 106 m and 188 m.

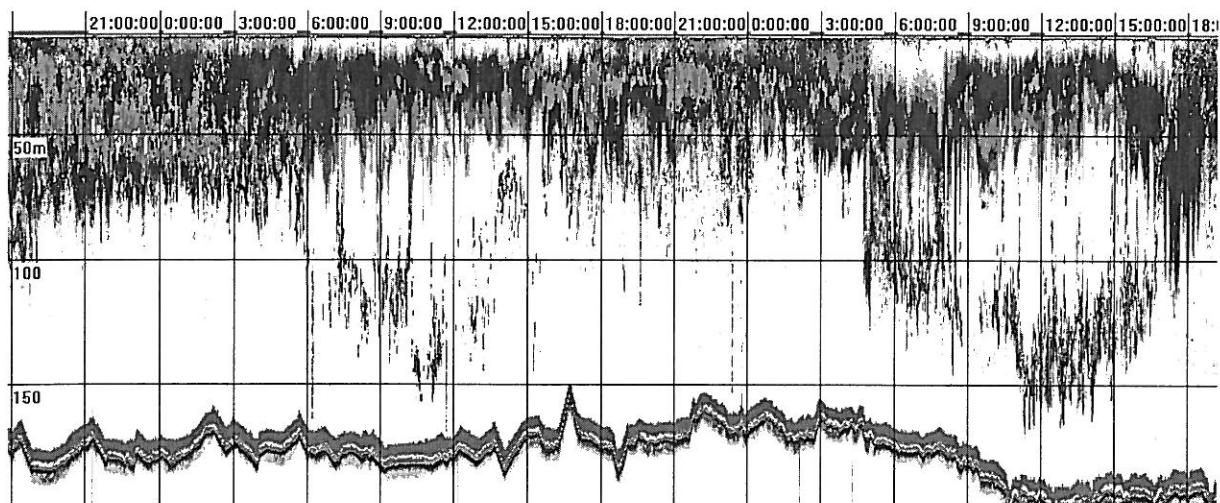

Figure 5. Composite figure of the acoustic recording from the 38 kHz transducer during diel experiment one. Time is GMT

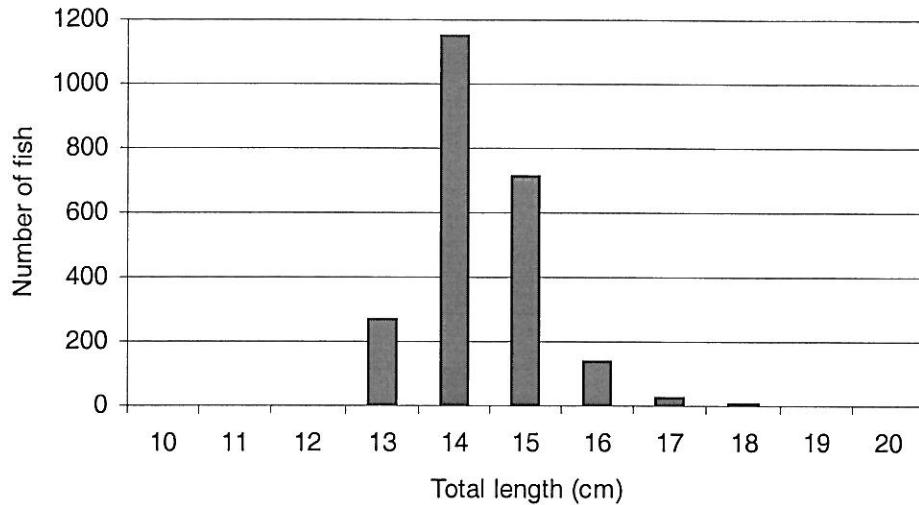

Figure 6. Length frequency of horse mackerel *Trachurus tracurus capensis* during the first diel cycle

The first diel cycle consisted of trawl stations 781-818 (ANNEX III and IV), all trawl hauls except 804-807 which were ordinary pelagic trawl hauls, were multisampler hauls. Station 808-810 was discarded because the multisampler malfunctioned. Most of the hauls were conducted on standard depths of 75 m 50 m and 25 m with 10-15 min trawls on each depth. Table 2 shows the catch/hour of horse mackerel during the experiment. The catches identify layers of horse mackerel in the echogram. Cycle 8-10 (station 804-807) was conducted as single hauls with an ordinary pelagic trawl in order to charge the multisampler battery. There were no horse mackerel in the trawl catches during cycle 5 and 7 and little in 8 and 9. The echogram (Figure 5) supports that horse mackerel moved out of the study area during this period. It was decided to move a few nm north and a little deeper to follow the fish, and good concentrations were found again in the morning 05:00 (cycle 10).

Table 2 Depth (m) and catch rate (kg/h) of horse mackerel during diel cycle 1. Time is GMT

1	2	3	4	5	6	7	8-10	11	12	13

Figure 7 shows the stomach filling of horse mackerel *T. trachurus capensis* and *T. trecae* during diel experiments one and two. The figure shows that both species of horse mackerel fed in the afternoon during the survey. The diet will be examined more closely on land, and compared to available zooplankton in the water column.

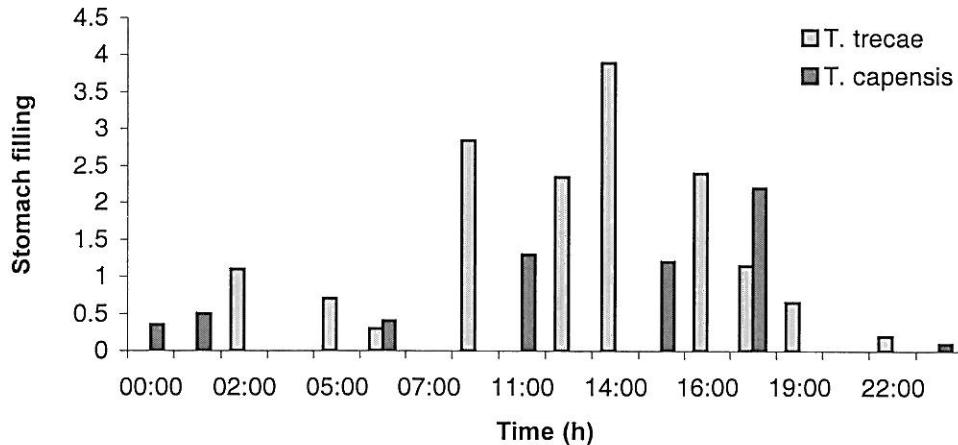

Figure 7 Preliminary analyses of the stomach filling of horse mackerel. Both *T. trachurus*, *T. capensis* and *T. trecae* were eating in late afternoon. Time is GMT.

3.3.2 Diel cycle II

A composite plot of the acoustic recordings from the 38 kHz transducer during the second diel experiment is shown in Figure 8. Acoustic scatters were present in the whole water column with slightly different distribution between day and night. The bottom depths in the area were less than 100 m.

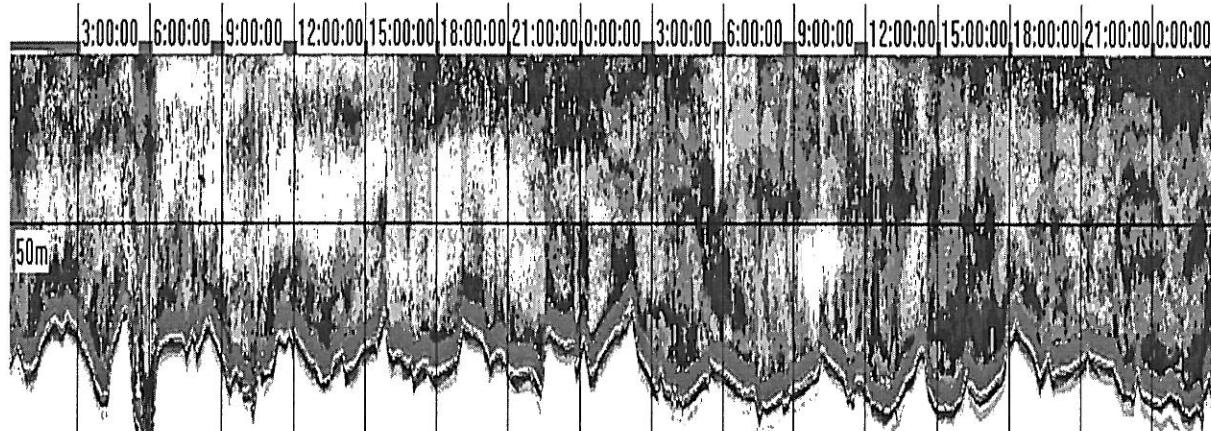

Figure 8. A composite plot of the acoustic recordings from the 38 kHz transducer during the second diel experiment. Time is GMT

The catch per hour of the main species are summarised for different depths and times of the day (Table 3). Day refers to 06:00-18:00 GMT. Only 2 multinet were normally released, one at depths deeper than 45 m, and one shallower than 30 m. The species composition during the experiment was complex. There were as expected large differences in the catch composition at different depths and between day and night. *Sardinella (S. maderensis)* dominated completely in shallow waters during the day, and in deeper layers >45 m depth at night. *Trichiurus lepturus*, *Brachydeuterus auritus* and horse mackerel (*T. trecae*) dominated in bottom trawls,

all with highest concentrations during the day. Adult horse mackerel were not present in bottom trawls at night while juvenile horse mackerel were not present in the water column during the day.

Table 3. Summary of main species composition in multinet and bottom trawls during diel cycle 2. The data is given as sum of catch per hour in kilos for all hauls.

SPECIES	<30m		>45m		Bottom trawl		Sum	% of total catch
	Day	Night	Day	Night	Day	Night

The length frequency of horse mackerel a) and sardinella b) is shown in Figure 9. Both length frequencies show that several different cohorts were present during the experiment. Juvenile horse mackerel and adult sardinella dominated. The data were not suitable for target strength experiments.

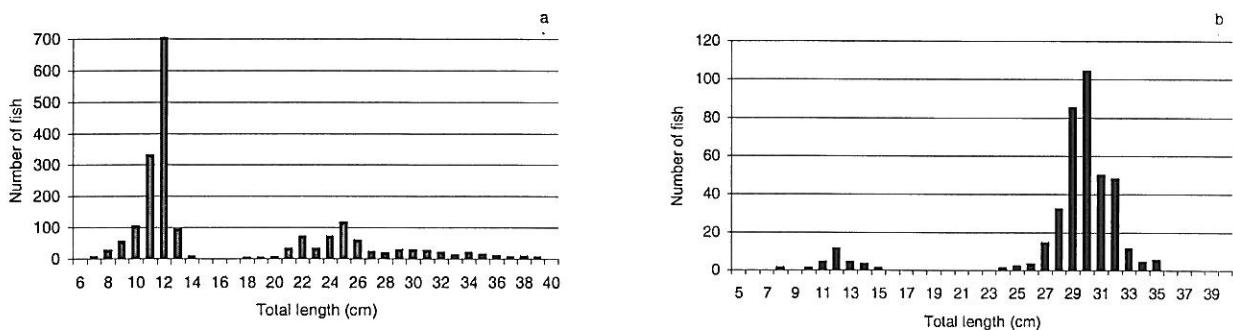

Figure 9. Length frequency of horse mackerel (*T. tracae*) a) and sardinella (*S. maderensis*) b) during the second diel cycle

3.4 *in situ* Target strength experiments

The single target echogram (38 kHz) used for target detection of horse mackerel during diel cycle one is shown side by side with the equivalent Sv echogram in Figure 10. The single target

detection algorithm in Echoview selected suitable candidates for TS measurements according to the criteria's in Table 1. No data was selected inside of the horse mackerel schools seen in the right echogram because these are too dense for single target experiments. The data was manually scrutinized to get rid of unwanted targets (marked "others" in the echogram, Figure 10). The preliminary TS data from the single target echogram was exported twice, first used before the manual scrutiny, and then after correction so that all of the targets were what we believed to be horse mackerel (Figure 11). The figure show that most of the values on the right tail of the TS distribution was discarded.

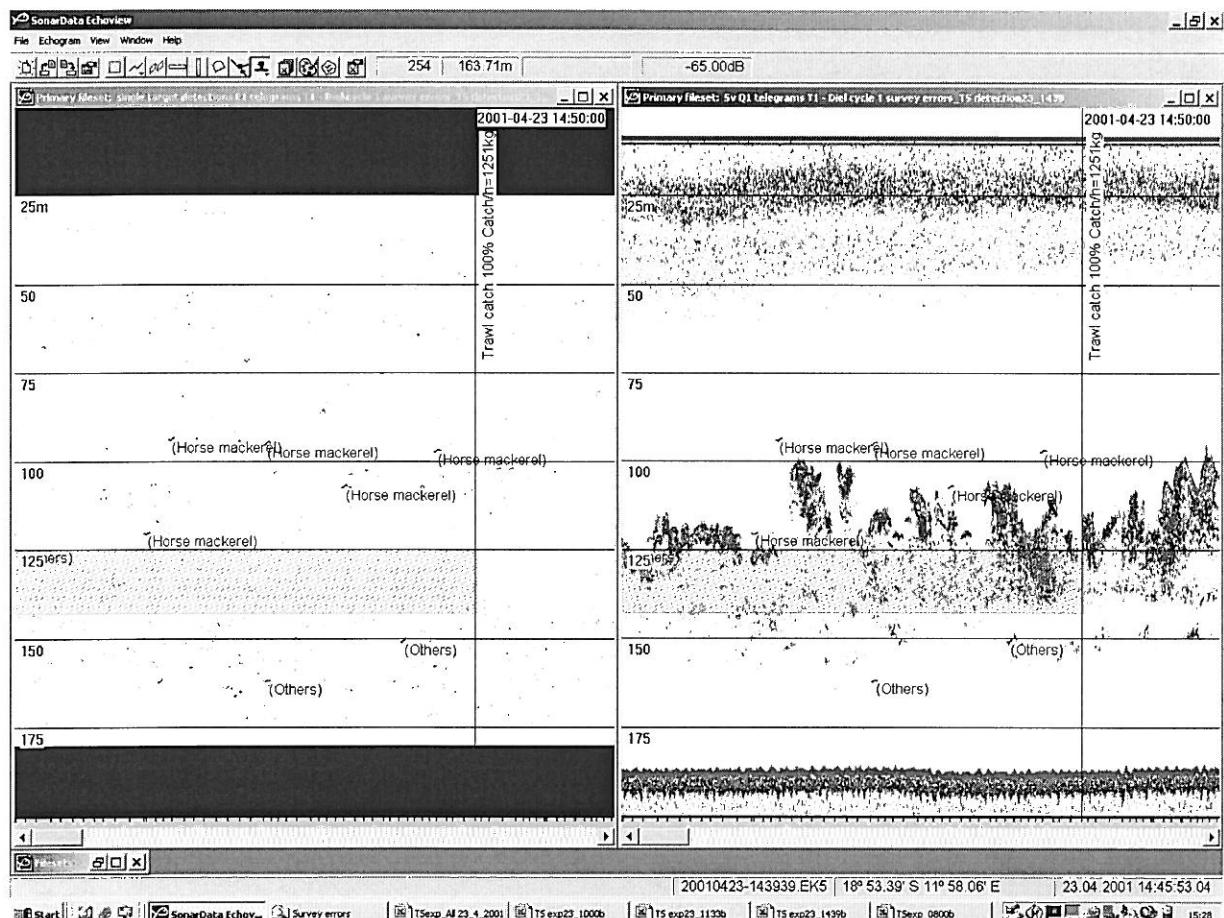

Figure 10. Example of single target detection echogram from the diel cycle one used for acoustic single target measurements of horse mackerel (left) including the excluded unwanted targets (others), and the equivalent Sv echogram (right). The red area on the echograms symbolise the trawl path that identified parts of the layer

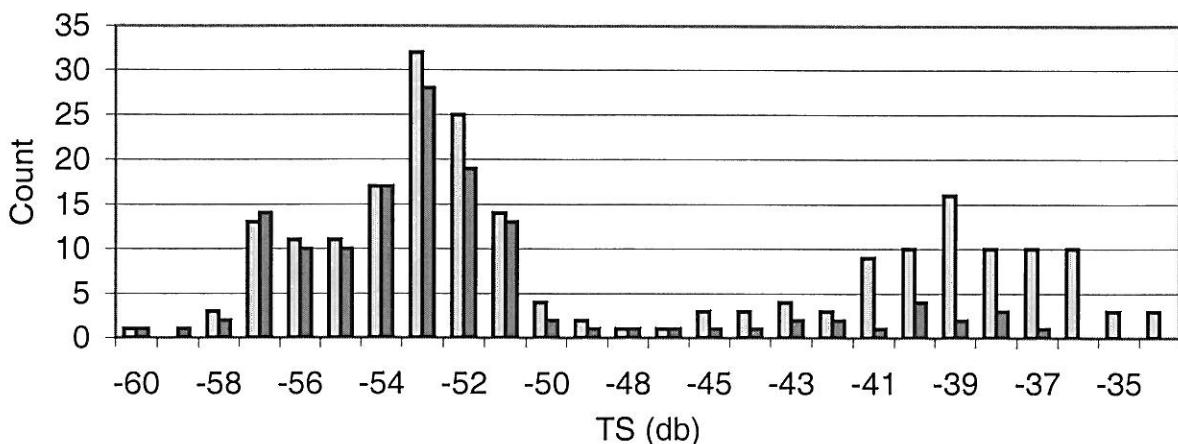

Figure 11. Distribution of acoustic single target measurements of horse mackerel (*T. trachurus capensis*) before (blue) and after (red) manual scrutiny of single targets.

Table 5 summarizes the result after the manual scrutiny, and the preliminary results suggest a B_{20} constant = -71.0 for cape horse mackerel in this situation. This is what is used during routine surveys today. However the results from this experiment illustrates the uncertainty around this value and highlights that manual scrutiny of single targets is essential even in relatively homogeneous layers of only one fish species like in this example. Manual scrutiny of the single targets has in this example excluded most of the unwanted targets, but it is suspected that some still remains. Unwanted targets can include fish that are so close together that they have been interpreted as a single individual with higher target strength, or other species not caught by the sample trawl. Further cleaning and manipulation of the data can produce the best approach ahead.

Table 5. Preliminary results of single target measurements of horse mackerel (*T. trachurus capensis*) after manual scrutiny of single targets.

n	Depth (m)	TS (dB)	B_{20}
	Mean	SD	
137	105.7	17.9	-47.8
			-71.0

3.4.1 Multifrequency acoustic analysis

As explained in the methods section, only data from suitably identified homogeneous scattering layers were used for the testing of the multifrequency target identification method. The basic idea is simple. Acoustic targets from a specific species / group have specific backscattering characteristics at different frequencies. The Sv ratios between two frequencies will be characteristic for the group and can be used to separate between different species or groups of species e.g. plankton and horse mackerel. The analysis of the multifrequency data requires a lot

of data processing, and will only be completed at a later stage. For the purposes of this report, only an example featuring distinct scattering layers of juvenile horse mackerel at three different frequency ratios from diel cycle one is presented (Figure 12). The horse mackerel show different characteristics for each of these frequency ratios. Note the peak around 0.1. This peak probably corresponds to small amounts of plankton mixed in the horse mackerel aggregations and could be filtered away from a new horse mackerel echogram using the Sv ratio information.

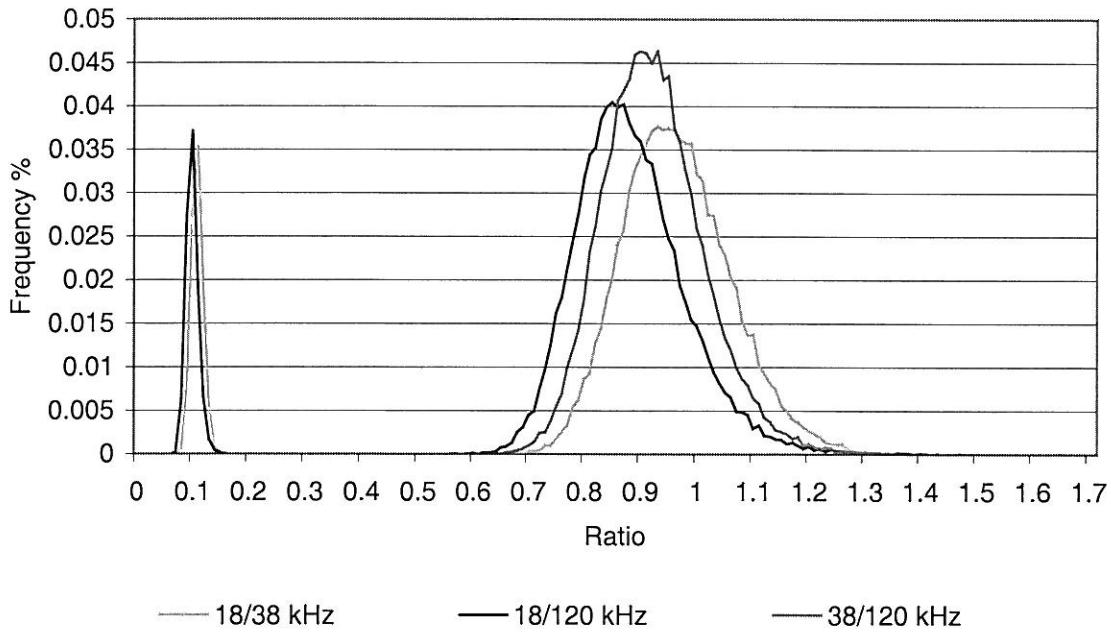

Figure 12. Ratios of Sv backscatter at 18 and 38 kHz a), 18 and 120 kHz b) 38 and 120 kHz c) for horse mackerel

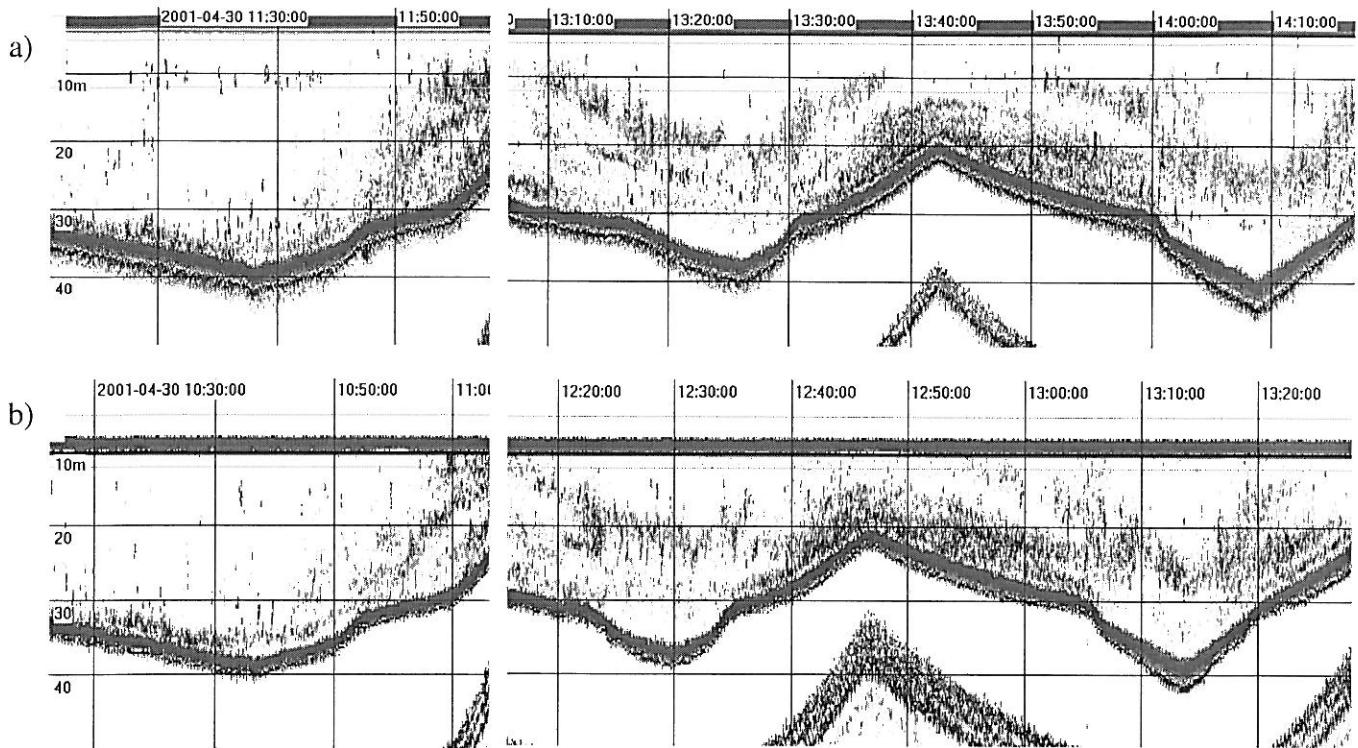

3.5 Vessel avoidance experiments

The vessel avoidance experiment was conducted with the MOB steaming in front of Dr. Fridtjof Nansen on transects with water depths of ~20 m – 50 m. Only data from two of the four mini surveys where suitable for avoidance studies. Visual scrutiny of the acoustic records suggested that the surveyed population consisted of a mix of sardinella (*S. maderensis*) and other pelagic species. This was confirmed by the trawl sample, which contained a mix of *S. maderensis* (22 %) other small pelagic (73 %) and some demersal (5 %) species (Annex III, station 869). The true ratio of the sardinella was, however, probably considerably higher, as the sardinella actively avoids the fishing gear and therefore is difficult to catch, particularly during the day (Misund et al., 1998).

The matched echograms from the two vessels are shown in Figure 13. The two vessels had different minimum integration depth (Figure 3, green line in Figure 13). The effective integration depth on Dr. Fridtjof Nansen is 12 m with the drop keel in lowered position, and the

transducer on the MOB was efficient from 5 m depth. The overall integration results from the two experiments show a consistent pattern with lower densities recorded with the Dr. Fridtjof Nansen than the MOB using the 5 m upper integration limit and higher densities using the 12 m limit (Table 6). The results suggest that the fish reacted to Dr. Fridtjof Nansen by vertical avoidance. The results showed that when integrating echograms from both vessels at 12 m (green line, Figure 13) the average s_A was lower for the MOB ($\langle s_A \rangle = 882$) than for the Dr. Fridtjof Nansen ($\langle s_A \rangle = 1030$) ($p < 0.04$, Sign permutation test). However, when the echogram from the MOB boat was integrated from 5 m depth (green line) they showed slightly higher but not significantly different ($\langle s_A \rangle = 1272$) readings to Dr. Fridtjof Nansen ($p < 0.64$, Sign permutation test). The results can be interpreted that the fish between 5 m and 12 m depth dived before passage of the research vessel. In this specific situation avoidance reaction seems to at least partly correct for another survey error namely fish in the surface dead zone. However, the experiments should be replicated, with special emphasis on potential effects of target density, vertical distribution and seasonal effects.

Experiment 1

Experiment 2

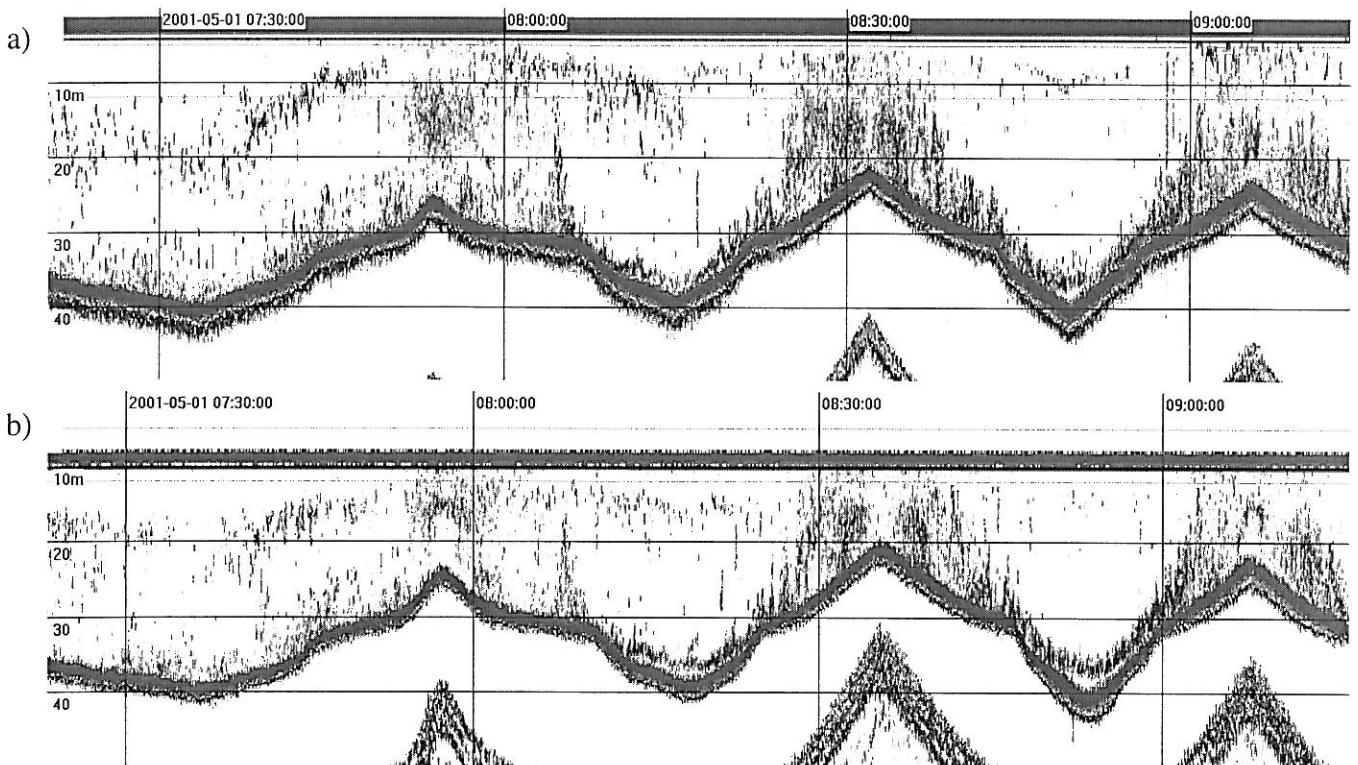

Figure 13. Echograms recorded by the MOB boat a) and Dr. Fridtjof Nansen b) during the experiment 1 and 2. The two green lines at 5 and 12 m water depth correspond to the integration levels in Table 6. The gap in the echogram during experiment 1 was created when the batteries to the EV500 on the MOB had to be charged.

Table 6. Comparative echo integration using the R/V “Dr. Fridtjof Nansen” (DFN) and the man-over-board boat (MOB) with different upper integration limits (subscript). Average s_A (m^2/nm^2) is given with corresponding standard error of the mean in brackets.

Experiment	DFN _{12m}	MOB _{5m}	MOB _{12m}
1	818 (79)	984 (266)	805 (185)
2	1265 (212)	1589 (346)	968 (167)
overall	1030 (113)	1272 (218)	882 (124)

5. ACKNOWLEDGEMENTS

This work was funded by the Benguela Environment Fisheries Interaction and Training Programme (BENEFIT). Thanks are extended to Reidar Johannessen and Magnar Mjanger for running the instruments and especially to Magne Olsen for his patience with oxygen titration, correction of the Nan-Sis database, and all other essential small and big tasks. A special thanks to the officers and crew on the *Dr. Fridtjof Nansen* for making everything work smoothly and for an unforgettable survey. One of the best!

ANNEX IV DIEL CYCLE DATASHEETS.

Dr. F. Nansen 2001 Survey errors, 48 hrs diel cycle experiment # 1

Target species: *T. trachurus capensis* juveniles (14-16 cm)

Position: ~19°00' S, 12°00'E

Bottom depth: ~160 m

Start: 21.04, 18:00 UTC (Multinet)

Stop: 23.04, 19:00 UTC (CTD/ ADCP)

Multinet depths: 1: 0-30, 2: 30-60, 3: 60-90, 4: 90-120, 5: 120-150

Multinet mesh size: 405 micrometer
