## CHAPTER 1 INTRODUCTION

---

### 1.1 Objective of the cruise

The general objectives were to estimate the biomass and map the distribution of small pelagic fish stocks off NW Africa (Morocco, Mauritania, Senegal and the Gambia) by hydro-acoustic methods and describe the hydrographic conditions there over a period of 50 days, in October-December 2001. For Senegal and the Gambia the agreed objectives were:

- To map the distribution and estimate the biomass for the main small pelagic fish using hydroacoustic methods. The species of interest were: sardinella *Sardinella aurita*, *Sardinella maderensis*, horse mackerel *Trachurus trachurus* and *T. trecae*, false scad *Decapterus rhonchus*, and anchovy *Engraulis encrasicolus*.
- To identify and describe the size distribution of the target fish populations by midwater and bottom trawl sampling and process the catches by recording weight and number by species.
- To sample standard hydrographical transects for temperature, salinity and oxygen at about 13°40' N and 14°50' N.

The time allocated for this part of the survey, off Senegal and the Gambia, was 10 days.

### 1.2 Participation

Members of the scientific teams were:

Centre de Recherches Océanographiques de Dakar-Thiaroy, Senegal:

Abdoulaye SARRE, Mor SYLLA, Mamadou SANE and Ibrahima SOW

Department of Fisheries, the Gambia:

Ousmann Mass JOBE, Solomon TAMOH and Juldah JALLOW,

Institute of Marine Research, Norway:

Reidar TORESEN, Magne OLSEN, Tore MØRK and Thor Egil JOHANSSON

### **1.3 Narrative**

The course tracks with the fishing and hydrographical stations are shown in Figure 1.

The survey started off Casamance on October the 29 with systematic parallel course tracks spaced about 10 NM (nautical miles) apart. To cover the whole distribution area of pelagic fish, the shelf was covered from the 15 m isobath and offshore to the 500 m isobath. Trawling was done irregularly, either to identify echo registrations or to check ‘blindly’ if fish were mixed with the plankton in the upper layers of the water column. In the latter case, pelagic trawl with floats was often used. A smaller pelagic trawl or the bottom trawl with floats was used for sampling the pelagic fish in very shallow waters (depth less than 25 m). The shelf was covered to about 30 NM (nautical miles) south of St. Louis. There we had to finish and return to Dakar, due to unexpected reasons. During the 7 November, the vessel made a second survey of the inner shelf between Dakar and the Gambia to study the variations in acoustic abundance estimation of small pelagic fish, and to shed light on the local migration of sardinella. This part of the survey will be reported later in a special report. The survey was finished in Dakar November 8.

The hydrographic profile off the Gambia was carried out on November 2 and that off Cape Vert on November 4.

### **1.4 Methods**

#### *Environmental Data*

Surface temperature and meteorological data from a weather station were logged automatically and recorded with position and bottom depth every nautical mile sailed.

Hydrographic profiles were collected with a CTD sonde and temperature, salinity, and pressure (depth) were logged by the Seabird Software. From these data series, records were selected from standard depths and presented in figures.

#### *Biological sampling*

Biological sampling of the fish was carried out using trawls. A pelagic trawl with floats was often used. A smaller pelagic trawl or the bottom trawl with floats was used for sampling the pelagic fish in very shallow waters (depth less than 25 m). Annex II gives a description of the instruments and the fishing gear used. All catches were sampled for composition by weight and numbers of each species caught. Species identification was based on the FAO Species Guides. Length frequency distributions, by total fish length in cm, of the selected target species were

taken in all the stations where they were present. Individual weight measurements were taken regularly to estimate the condition factor in the length-weight relationship:

$$\overline{w} = \frac{cond}{100} \cdot L^3$$

The specific condition factors obtained from the samples and applied for this survey were: 0.96 for sardinellas and horse mackerels.

For the estimation of the biomass of carangids and associated species, an overall average length of 23 cm and a condition factor of 0.88 (to calculate the mean length of this length group) were applied.

All data on fishing stations and fish length sampling were made available to the participants on diskettes.

The complete records of fishing stations are shown in Annex I.

The following target groups were used for Senegal:

- 1) Sardinellas (flat sardinella *Sardinella maderensis* and round sardinella *S. aurita*),
- 2) Horse mackerels (Cunene horse mackerel *Trachurus trecae*, round scad *Decapterus punctatus*, and false scad *Decapterus rhonchus*),
- 3) Other pelagic carangids and associated species (Atlantic bumper *Chloroscombrus chrysurus*, African lookdown *Selene dorsalis*, chub mackerel *Scomber japonicus*, largehead hairtail, *Trichiurus lepturus*, and barracudas *Sphyraena* spp.),
- 4) Other demersal species (such as bigeye grunt *Brachydeuterus auritus*, Sparidae and Haemulidae), and
- 5) Other clupeids such as West African ilisha *Ilisha africana*.

### *Acoustic sampling*

A SIMRAD EK500 Echosounder was used with the settings as shown in Annex II. The Bergen Integrator (BEI) was used for analysis and allocation of the integrated  $s_A$ -values to the individual specified target groups by 5 NM intervals. The allocation of values to target groups was based on a combination of a visual scrutiny of the behaviour pattern as deduced from echo diagrams, the BEI analysis, and the catch compositions.

In cases where the target category of fish contains more than one species (sardinellas and horse mackerels), the mean  $s_A$ -value allocated to the category is divided between the species in the same ratio as their contribution to the mean back scattering strength in the length frequency samples.

The following target strength (TS) function was applied to convert  $s_A$ -values (mean integrator value for a given species or group of species in a specified area) to number of fish:

$$TS = 20 \log L - 72 \text{ dB}$$

Which can be converted (see Toresen *et al.* 1998 for details) to the area form (scattering cross sections of acoustic targets):

$$C_{Fi} = 1.26 \cdot 10^6 \cdot L^{-2}$$

where  $L$  is total length in 1 cm length group  $i$  and  $C_{Fi}$  ( $\text{m}^{-2}$ ) is the reciprocal back scattering strength, or so-called fish conversion factor. In order to split and convert the allocated  $s_A$ -values ( $\text{m}^2/\text{NM}^2$ ) to fish densities (numbers per length group per  $\text{NM}^2$ ), the following formula was used:

$$\rho_i = s_A \cdot \frac{p_i}{\sum_{i=1}^n \frac{p_i}{C_{Fi}}}$$

where

$\rho_i$  = density of fish in length group  $i$

$s_A$  = mean integrator value

$p_i$  = proportion of fish in length group  $i$

$$\sum_{i=1}^n \frac{p_i}{C_{Fi}} = \text{the relative back scattering cross section (m}^2\text{) of the length frequency}$$

sample of the target species, and

$C_{fi}$  = reciprocal back scattering cross section ( $\sigma_{bs}^{-1}$ ) of a fish in length group  $i$ .

The integrator outputs were split in fish groups using a combination of behaviour pattern as deduced from echo diagrams, the BEI analysis and catch composition as described below. The following groups were used for Senegal: 1) sardinellas, 2) horse mackerels, 3) carangids and associated species, and 4) demersal fish.

The above equations show that the conversion from  $s_A$ -values to number of fish is dependent on the length composition of the fish. It is therefore important to get representative length distributions from the stock in the whole distribution area.

When the size classes (of e.g. young fish and older fish) are well mixed, the various length distributions can be pooled together with equal importance. Otherwise, when the size classes are segregated, the total distribution area has to be post-stratified, according to the length distributions, and separate estimates are made for the regions containing fish with equal size.

For a region representing a distribution of a target-species, the following basic data are needed for the estimation of abundance; 1) the average  $s_A$ -value for the region, 2) the surface (usually  $NM^2$ ), and 3) a representative length distribution of the fish in the region. If the targeted fish is a mixture of more than one species, for example sardinellas, a representative distribution of the two, within the region, as shown in the trawl catches, are used. A length distribution representing the number of the two species for each catch will have to be calculated. Thereafter, these distributions have to be normalized to a unit number (usually 100) so they are equally weighted.

A systematic approach to a) divide the  $s_A$ -value between species in a category of fish (e.g. *Sardinella aurita* and *S. maderensis*) and b) produce pooled length distributions of a target species for use in the above equation and c) calculate the biomass estimates for a region, is obtained through the following procedure:

- The samples of the species in the category (e.g. sardinellas) are respectively pooled together with equal importance (normalized).
- The mean back scattering strength ( $\rho/s_A$ ) of each length frequency distribution of the target species is calculated and summed. This is automatically done in the Excel

spreadsheet made available for acoustic abundance estimation onboard R/V “Dr. Fridtjof Nansen”, provided the data are punched in this sheet.

- The mean  $s_A$ -value allocated to the category of fish in the region is divided between the species in the same ratio as their relative contribution to the mean back scattering strength of the length groups in the sample representing the region (also automatically done in the Excel spread-sheet given that the  $s_A$ -value for the region is punched into the sheet).
- The pooled length distribution is used, together with the mean  $s_A$ -value, to calculate the density (numbers per square NM) by length groups and species, using the above formula. The total number by length group in the area is obtained by multiplying each number by the area. (This is done in the Excel spreadsheet, given that the area of the region is punched into the sheet).
- The numbers are converted to biomass using the estimated weight at length. (Done in the Excel sheet if the condition factor is punched).

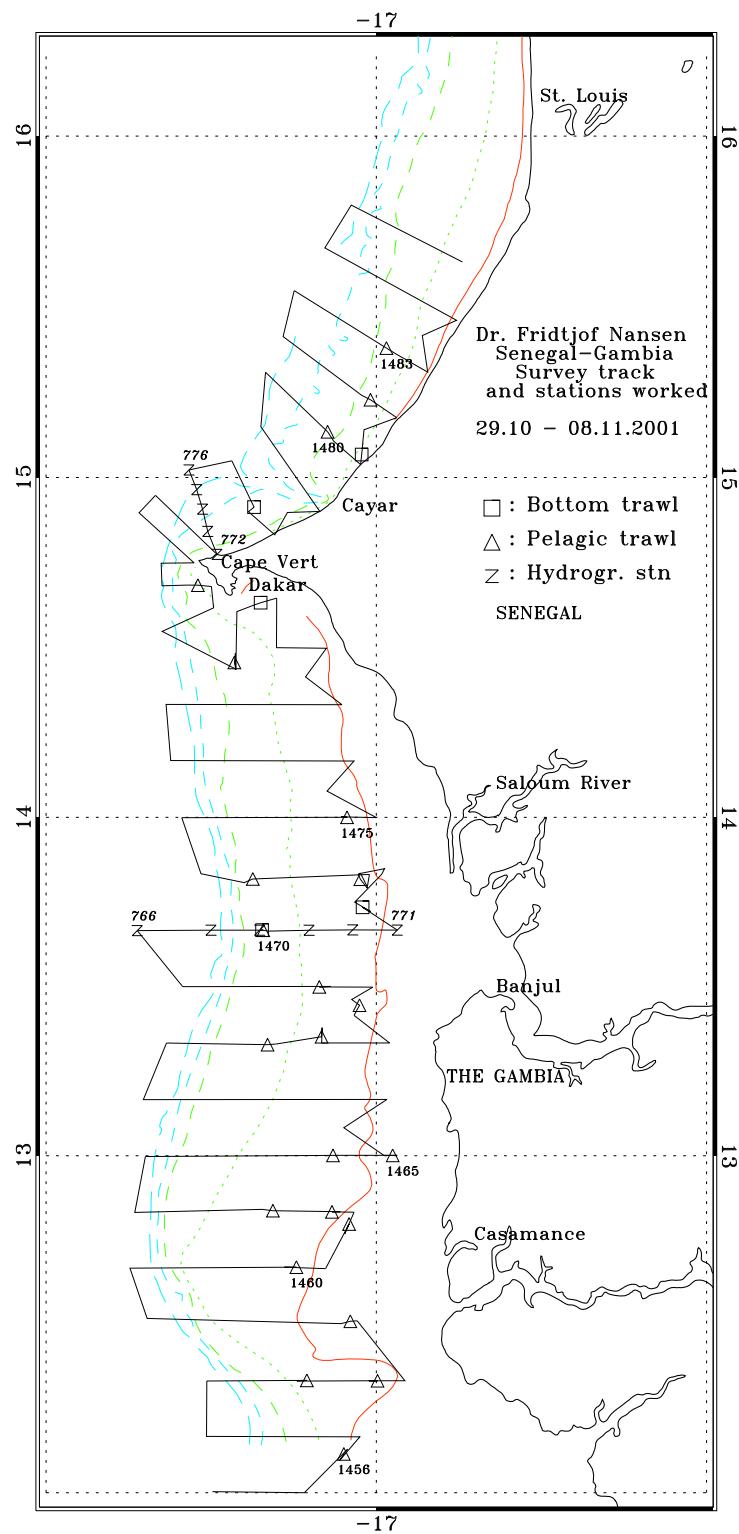

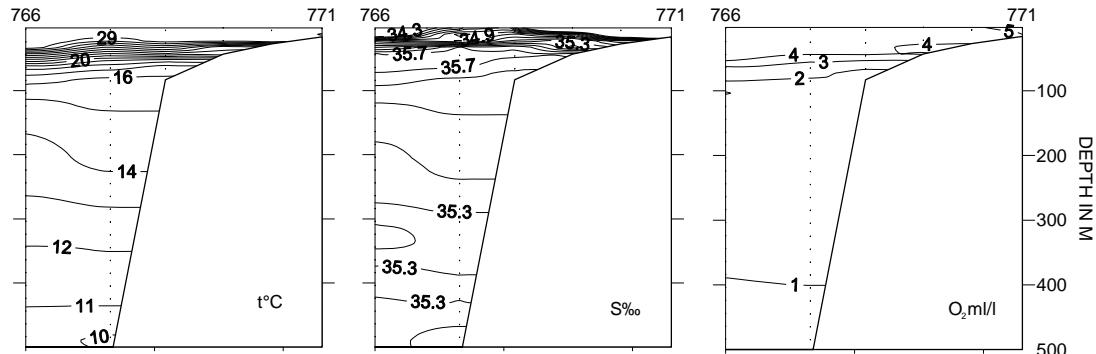

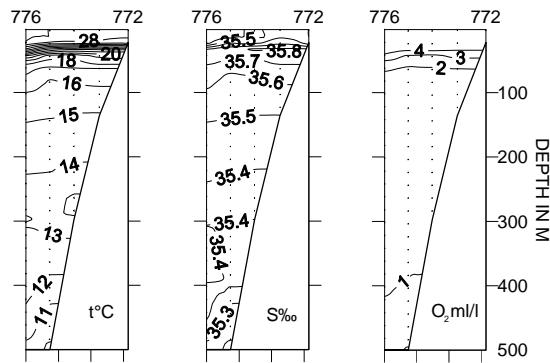

Figure 1 Course tracks with fishing and hydrographic stations; Casamance to St. Louis

## CHAPTER 2 SURVEY RESULTS

---

### 2.1 Hydrography

Figure 2 shows the distribution of temperature, salinity and oxygen in the two profiles and Figure 3 the sea surface temperature at 5 m of depth.

THE GAMBIA - WEST 04.11 2001

Figure 2 Hydrographic profiles with distribution of temperature, salinity and oxygen.

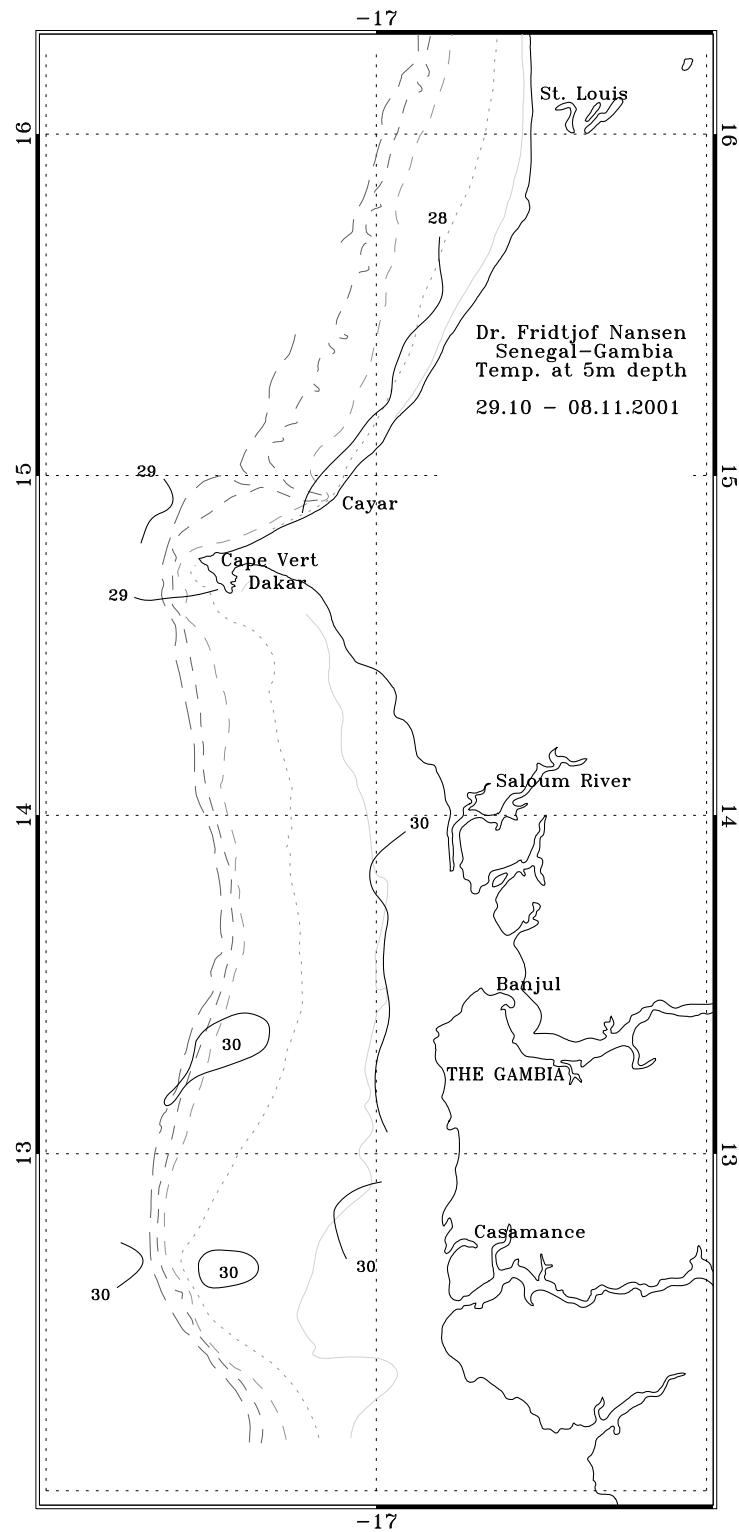

Figure 3 Sea surface temperature; Casamance to St. Louis.

The distribution of surface temperature and the profile the Gambia-west show that there was a stable surface layer with a temperature of 29-30 °C over the whole shelf south of Dakar. North of Cape Vert there was a stable surface layer with a temperature of 27-29 °C. Both profiles show that there is a profound hydrographic cline in about 20 m depth.

## 2.2 The Casamance shelf

Figures 4, 5 and 6 show the distributions of the main groups of pelagic fish by contoured acoustic densities for the whole shelf of Senegal and the Gambia.

Off the Casamance coast, there was a continuous school area of sardinella of medium and high density in shallow waters, mostly inside the 25 m depth line (Figure 4). The samples from this aggregation were predominantly (95%) *Sardinella maderensis*. The modal size was 23 and 26 cm (total length). The size composition is shown in Annex III, and the stock length compositions by numbers and weight in Annex IV. The total biomass of sardinellas in the area was estimated at 87 000 tonnes, Table 1.

Small concentrations of horse mackerel, *Trachurus trecae*, were found at the outer shelf of Casamance. It consisted of medium sized fish with modal length of 21 cm. The biomass was estimated at 8 000 tonnes, Table 1.

Other pelagic fish were found in rather low densities, but over a wider area than the sardinellas, see Figure 6. The trawl samples indicated that these consisted of bumper, lookdown and barracudas with the bumper as the dominating species. The estimated biomass of this group of fish was 134 000 tonnes.

Table 1. Casamance. Biomass estimates of pelagic fish, 1 000 tonnes.

Flat sardinella	Round sardinella	Horse mackerels	Carangids etc
83	4	8	134

## 2.3 The Gambian shelf

The school area of sardinella found off Casamance continued northwards off the Gambia, Figure 4. The highest concentrations were recorded as a medium to high-density area some 20 NM off the coast. The samples showed a 61% dominance of round sardinella, *Sardinella aurita*, with a smaller proportion of flat sardinella, *S. maderensis*. The pooled length composition

of the round sardinella had a modal length of 17 cm, see Annex III. The stock length compositions by numbers and weight are shown in Annex IV.

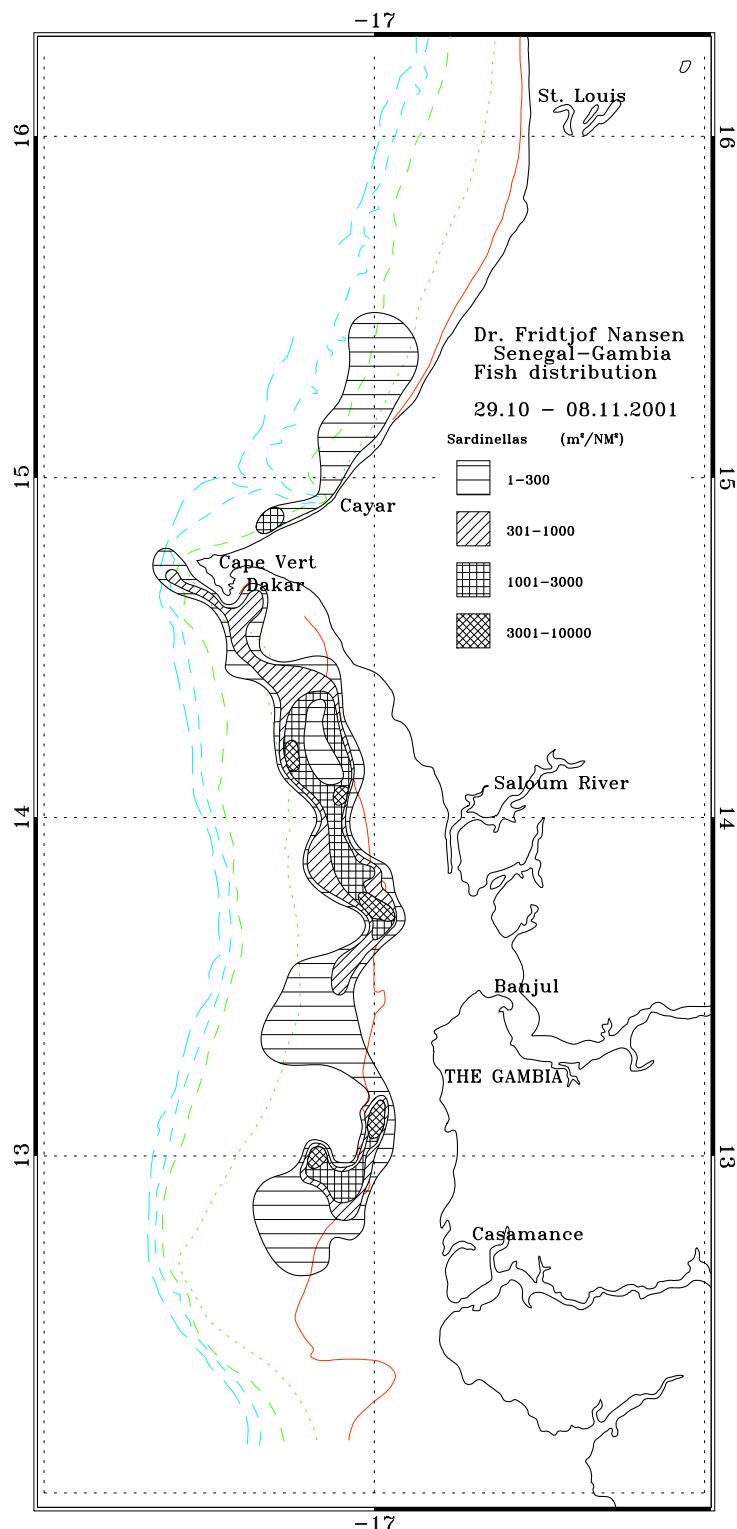

Figure 4 Distribution of sardinellas; Casamance to St. Louis.

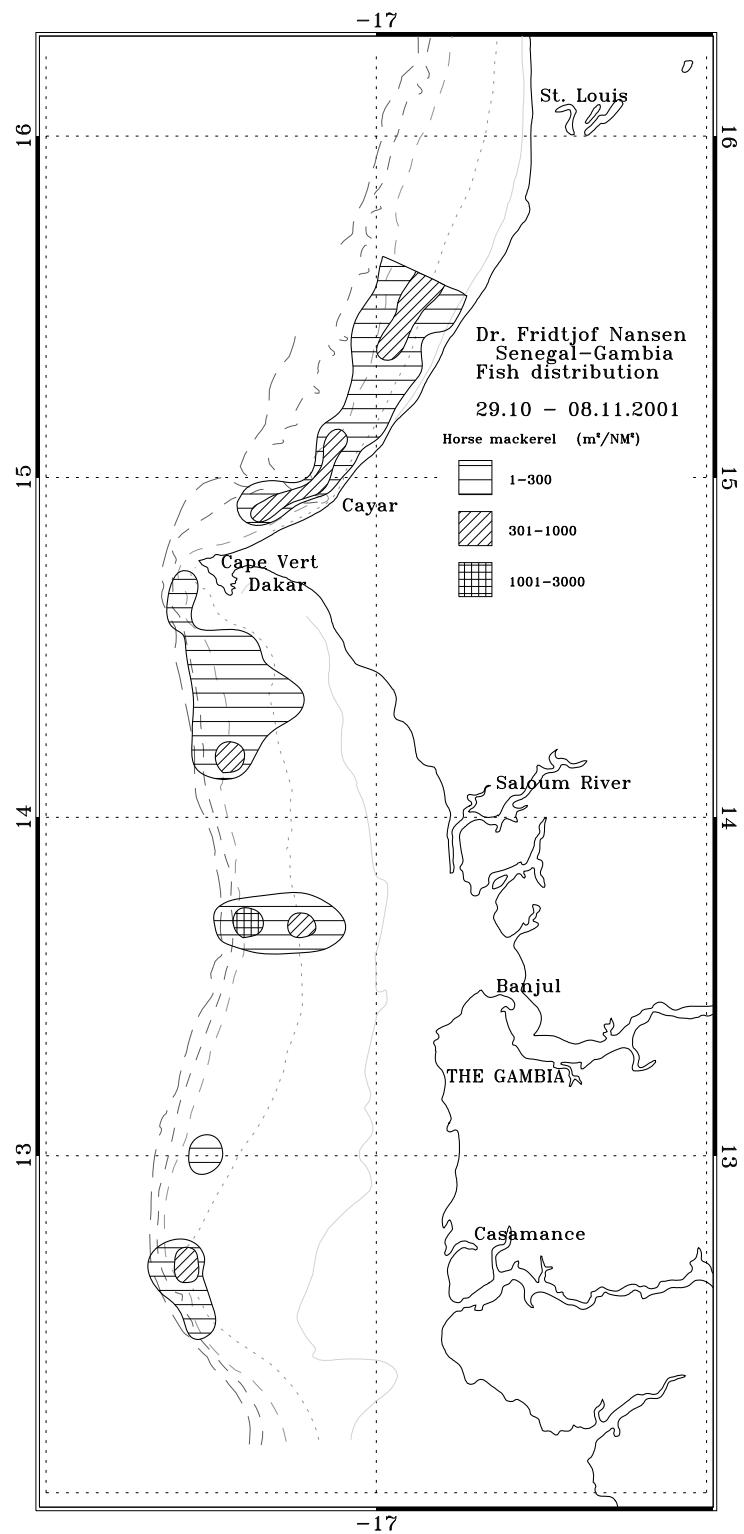

Figure 5 Horse mackerels; Casamance to St. Louis.

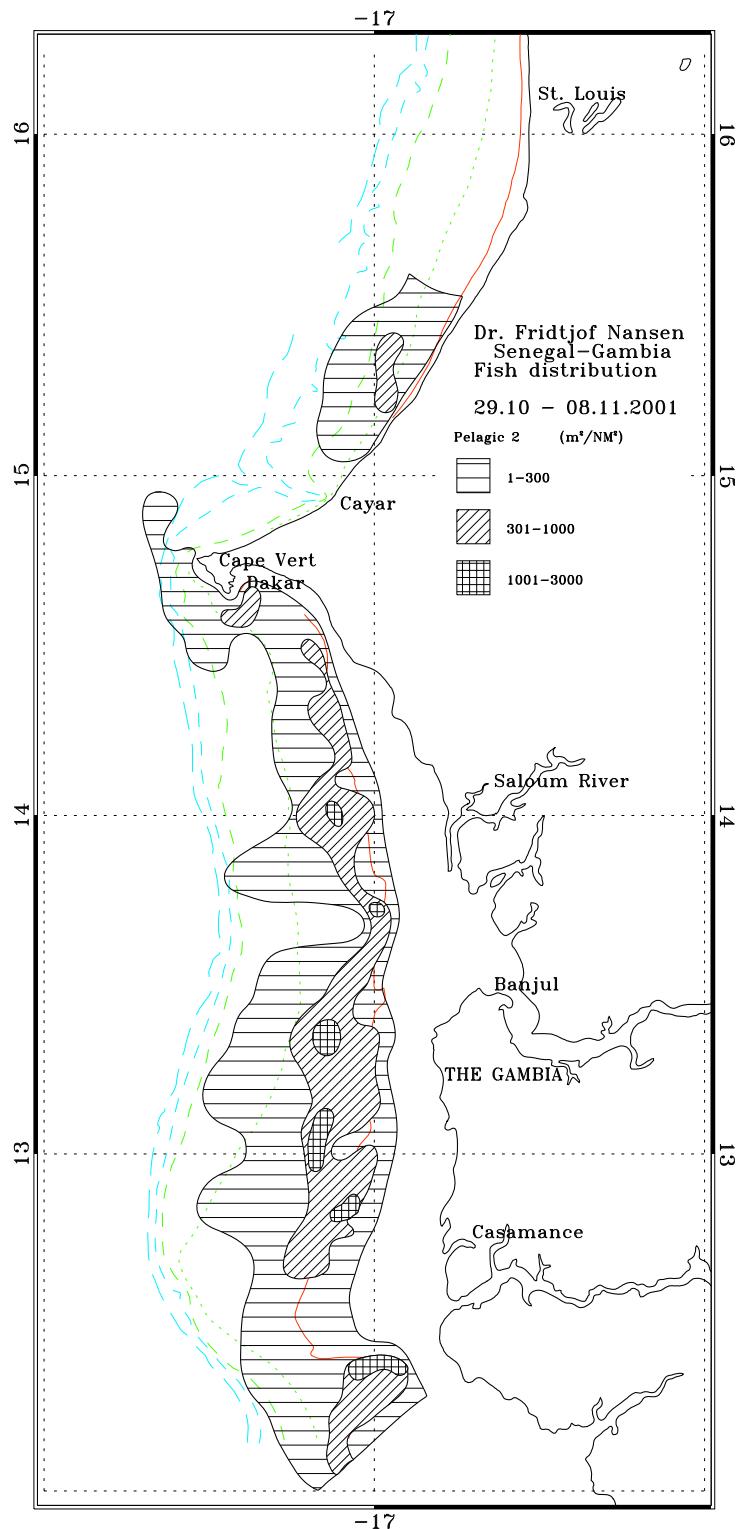

Figure 6. Carangids and associated species; Casamance to St. Louis

Table 2 shows that the biomass estimates of the sardinellas amounted to 54 000 tonnes, of which 33 000 tonnes were round sardinella.

No horse mackerels were found in the Gambia during this survey.

Carangids and associated species were found widely distributed over the inner shelf, Figure 6. Catches of this group consisted mainly of bumper, African lookdown and barracudas. The biomass was estimated to about 110 000 tonnes.

Table 2. The Gambia. Biomass estimates of pelagic fish, 1 000 tonnes.

Flat sardinella	Round sardinella	Horse mackerels	Carangids etc.
21	33	0	111

## 2.4 The Gambian border - Cape Vert

Sardinellas were distributed from the outlet of the Saloum River to Dakar, Figure 4. The greatest densities were found some 20 NM southwest of the outlet of Saloum River. Table 3 shows the biomass estimates for the two sardinella species that summed up to 291 000 tonnes. Flat sardinella dominated the estimated biomass in the area by 55%.

Pooled length compositions of samples showed that the flat sardinella had a modal length of 8 and 23 cm while the round sardinella had modal lengths of 20, 22 and 30 cm, see Annex III. Stock size compositions by numbers and weight are shown in Annex IV.

The horse mackerels in this area were distribution in two main areas, one some 30 NM west of the outlet of the Saloum River and the other south of Cape Vert, Figure 5. The total biomass was estimated at some 81 000 tonnes of which 96% were Atlantic horse mackerel, *Trachurus trecae*. The modal length of the horse mackerel in this area was 21 cm.

Also here, the carangids and associated pelagic fish, were distributed over most of the area with the highest concentrations between the Saloum River and Dakar, see Figure 5. Again, bumper was caught in most of the trawl samples. The biomass of the carangids and associated pelagic fish was estimated at about 85 000 tonnes, Table 3.

Table 3. The Gambia border to Cape Vert. Biomass estimates of pelagic fish, 1 000 tonnes.

Flat sardinella	Round sardinella	Horse mackerels	Carangids etc.
159	132	81	85

## 2.5 Cape Vert - St. Louis

Sardinella were distributed inshore along the coast, from about 10 NM northeast of Cape Vert to about 30 NM north of Cayar, Figure 4. Only small flat sardinella were found, with a modal length of 8 cm. The total biomass was estimated at 2 000 tonnes.

Horse mackerel were found at low to medium densities along the inner shelf in an area extending from about 10 NM north of Dakar to the point where the survey was finished (some 40 NM north of Cayar, Figure 5. The total biomass was estimated at 39 000 tonnes, and the catches consisted of Atlantic horse mackerel only. The modal length was 22 cm.

Carangids and associated pelagic fish were mainly found in an area from some 10 NM north of Cayar and northwards to the finish of the survey. A smaller aggregation was found off Cape Vert, Figure 6. The catches consisted also here of bumper and African lookdown. The biomass estimate was 17 000 tonnes.

Table 4. Cape Vert to St. Louis. Biomass estimates of pelagic fish, 1 000 tonnes.

Flat sardinella	Round sardinella	Horse mackerels	Carangids etc.
2	-	39	17

## CHAPTER 3      OVERVIEW AND SUMMARY OF RESULTS

---

The survey was conducted successfully in the period October 29 to November 8 with a course track of about 1 500 NM and 28 fishing stations. The fact that the survey had to be terminated before the total area was covered has probably minimal effect on the total estimates of the various species.

The hydrographical data showed a stable surface layer for the whole shelf, on average one degree colder north of Dakar than to the south of this city.

Sardinellas were found in two main areas; one long distribution extending from Casamance to Cape Vert and another at the coast near Cayar, Figure 4. High densities were found in the southernmost parts of the Gambia and to the west of the outlet of the Saloum River. Flat sardinella dominated in all areas, except in the Gambia.

Horse mackerels were found in two main areas; one south off Dakar, and the other north of Dakar. In addition horse mackerels were found at the outer shelf west of Saloum River and southwards, Figure 5.

South of Cape Vert, the carangids and associated species were distributed over most of the shelf at rather low to medium densities, Figure 5. The catches of this group consisted of bumper, barracudas and hairtails. North of Cape Vert, the carangids were distributed over the shelf in the northernmost part of the region.

An overview of the acoustic estimates of biomass of the main groups of pelagic fish is shown in Table 5. The total biomass of sardinellas was thus 434 000 tonnes, horse mackerels – 128 000 tonnes and of carangids and associated species - 347 000 tonnes.

Table 5. Summary of biomass estimates of pelagic fish, Senegal and the Gambia. 1 000 tonnes.

	Flat sardinella	Round sardinella	Horse mackerels	Carangids etc.
St. Louis-Cape Vert	2	-	39	17
Cape Vert-Gambia	159	132	81	85
Gambia	21	33	-	111
Casamance	83	4	8	134
Total	265	169	128	347

Table 6 lists biomass estimates of sardinellas and carangids (including the horse mackerels) and associated species from the 'Dr. Fridtjof Nansen' surveys of this shelf region. Large-scale latitudinal movements of pelagic fish between West Sahara and Guinea Bissau are well known. Compared with the November-December estimates in earlier years, this year's estimate of 434 000 tonnes of sardinellas is higher than those of the years 2000, 1998, 1997 and 1996. The carangid estimate of 475 000 tonnes is at the same level as the estimates in 2000 and 1999.

Table 6. Biomass estimates from previous 'Dr Fridtjof Nansen' surveys of the Senegal-the Gambia shelf. 1 000 tonnes.

## **Annex II Instruments and fishing gear used**

The Simrad EK-500, 38kHz echo scientific sounder was used during the survey for fish abundance estimation. The Bergen Echo Integrator system (BEI) logging the echogram raw data from the sounder, was used to scrutinize the acoustic records, and to allocate integrator data to fish species. All raw data was stored to tape, and a backup of the database of scrutinized data, stored. The details of the settings of the 38kHz were as follows:

<b>Transceiver-1 menu</b>	Transducer depth	5.5 - 7.5 m
	Absorption coeff.	10 dB/km
	Pulse length	medium (1ms)
	Bandwidth	wide
	Max power	2000 Watt
	2-way beam angle	-21.0 dB
	SV transducer gain	27.16 dB
	TS transducer gain	27.26 dB
	Angle sensitivity	21.9
	3 dB beamwidth Along.	7.1°
	3 dB beamwidth Athw.	6.9°
	Alongship offset	0.07°
	Athwardship offset	0.03°
<b>Display menu</b>	Echogram	1
	Bottom range	10 m
	Bottom range start	9 m
	TVG	20 log R
	Sv colour min	-67 dB
	TS Colour minimum	-60 dB
<b>Printer- menu</b>	Range	0 - 50 or 0 -100 m and 100 - 350m
	TVG	20 log R
	Sv colour min	-60 dB
<b>Bottom detection menu</b>	Minimum level	-40 dB

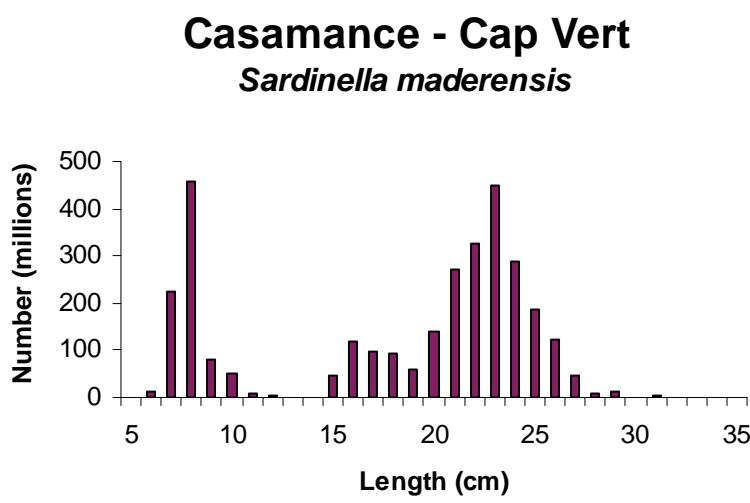

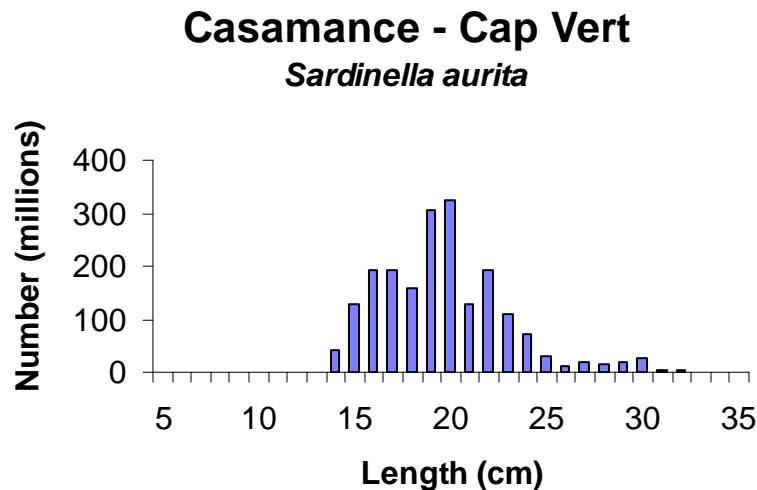

A calibration experiment using a standard wolfram carbide sphere, performed off Langstrand, Walvis Bay 8 September 2001 gave the following results:

Sv Transducer gain 27.16 dB  
Ts Transducer gain 27.26 dB

### **Fishing gear**

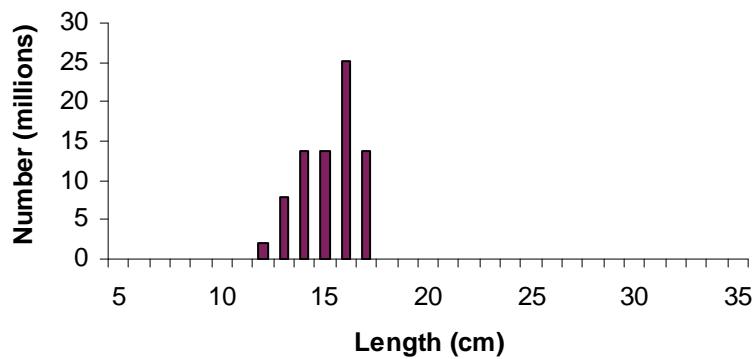

The vessel has two different sized "Åkrahamn" pelagic trawls and one "Gisund super" bottom trawl. For all trawls, the Tyborøn, 7.8m<sup>2</sup> (1670 kg) trawl doors were used.

ANNEX IV    Stock length distribution by numbers and weight	

## **CHAPTER 1      INTRODUCTION**

---

### **1.1 Objective of the cruise**

The general objectives were to estimate the biomass and map the distribution of small pelagic fish stocks off NW Africa (Morocco, Mauritania, Senegal and the Gambia) by hydro-acoustic methods and describe the hydrographic conditions there over a period of 50 days, in November-December 2001. For Mauritania the agreed objectives were:

- To map the distribution and estimate the biomass of the main small pelagic fish using hydroacoustic methods. The species of interest are: sardine *Sardina pilchardus*, sardinella *Sardinella aurita*, *S. maderensis*, horse mackerels *Trachurus trachurus* and *T. trecae*, false scad *Decapterus rhonchus*, and anchovy *Engraulis encrasicolus*.
- To identify and describe the size distribution of the target fish populations by midwater and bottom trawl sampling and process the catches by recording weight and number by species.
- To sample standard hydrographical transects for temperature, salinity and oxygen at about 16°40' N, 18°00' N, 19°00' N, 20°00' N and off Cape Blanc.

The time allocated for this part of the survey, off Mauritania, was 10 days.

### **1.2 Participation**

Members of the scientific teams were:

Institut Mauritanien de Recherches Océanographiques et des Pêches, Mauritania:

Bambaye Ould HAMADI, Diallo IBRA, Cheikh Tijane DIOP and Ebaye Ould SIDINA

Centre de Recherches Océanographiques de Dakar-Thiaroy, Senegal:

Mor SYLLA

Department of Fisheries, the Gambia:

Juldah JALLOW

Institute of Marine Research, Norway:

Reidar TORESEN, Magne OLSEN, Tore MØRK and Thor Egil JOHANSEN

### 1.3 Narrative

After embarking of scientists from Mauritania, Senegal and the Gambia, the survey of the Mauritanian shelf started on November the 10, at the border between Mauritania and Senegal, with systematic parallel course tracks spaced about 10 NM (nautical miles) apart. To cover the whole distribution area of pelagic fish, the shelf was covered from the 15 m isobath and offshore to the 500 m isobath. Trawling was done irregularly, either to identify echo registrations or to check ‘blindly’ if fish were mixed with the plankton in the upper layers of the water column. In the latter case, pelagic trawl with floats was often used. A smaller pelagic trawl or the bottom trawl with floats was used for sampling the pelagic fish in very shallow waters (depth less than 25 m). The shelf was covered northwards to Cape Blanc before a call was made in Nouakchott on November 17, to let participants from Senegal, the Gambia and Mauritania disembark and scientists from Morocco come onboard.

The hydrographic profile at 16°40' N was sampled on 10 November, at 18°00' N on 13 at 19°00' N on 14 at 20°00' N on 15 and off Cape Blanc on the part of the survey covering Morocco.

The survey was terminated in Nouakchott on 17 November.

### 1.4 Methods

#### *Environmental Data*

Surface temperature and meteorological data from a weather station were logged automatically and recorded with position and bottom depth every nautical mile sailed.

Hydrographic profiles were collected with a CTD sonde and temperature, salinity, and pressure (depth) were logged by the Seabird Software. From these data series, records were selected from standard depths and presented in figures.

#### *Biological sampling*

Biological sampling of the fish was carried out using trawls. A pelagic trawl with floats was often used. A smaller pelagic trawl or the bottom trawl with floats was used for sampling the pelagic fish in very shallow waters (depth less than 25 m). Annex II gives a description of the instruments and the fishing gear used. All catches were sampled for composition by weight and numbers of each species caught. Species identification was based on the FAO Species Guides. Length frequency distributions, by total fish length in cm, of the selected target species were taken in all the stations where they were present. Individual weight measurements were taken regularly to estimate the condition factor in the length-weight relationship:

$$\overline{w} = \frac{cond}{100} \cdot L^3$$

The specific condition factors obtained from the samples and applied for this survey were: 0.96 for sardinellas and horse mackerels, and 0.54 for anchovy.

For the estimation of the biomass of carangids and associated species, an overall average length of 23 cm and a condition factor of 0.88 (to calculate the mean length of this length group) were applied.

All data on fishing stations and fish length sampling were made available to the participants on diskettes.

The complete records of fishing stations are shown in Annex I.

The following target groups were used for Mauritania:

- 1) Sardinellas (flat sardinella *Sardinella maderensis* and round sardinella *S. aurita*),
- 2) Horse mackerels (Atlantic horse mackerel *Trachurus trachurus*, Cunene horse mackerel *Trachurus trecae*, and false scad *Decapterus rhonchus*),
- 3) Chub mackerel *Scomber japonicus*
- 4) Other pelagic carangids and associated species (Atlantic bumper *Chloroscombrus chrysurus*, African lookdown *Selene dorsalis*, largehead hairtail *Trichiurus lepturus*, and barracudas *Sphyraena* spp.),
- 5) Other demersal species (such as bigeye grunt *Brachydeuterus auritus*, Sparidae and Haemulidae), and
- 6) Other clupeids such as West African ilisha *Ilisha africana*.

#### *Acoustic sampling*

A SIMRAD EK500 Echo-sounder was used with the settings as shown in Annex II. The Bergen Integrator (BEI) was used for analysis and allocation of the integrated  $s_A$ -values to the individual specified target groups by 5 NM intervals. The allocation of values to target groups was based on a combination of a visual scrutiny of the behaviour pattern as deduced from echo diagrams, the BEI analysis, and the catch compositions.

In cases where the target category of fish contains more than one species (sardinellas and horse mackerels), the mean  $s_A$ -value allocated to the category is divided between the species in the

same ratio as their contribution to the mean back scattering strength in the length frequency samples.

The following target strength (TS) function was applied to convert  $s_A$ -values (mean integrator value for a given species or group of species in a specified area) to number of fish:

$$TS = 20 \log L - 72 \text{ dB}$$

Which can be converted (see Toresen *et al.* 1998 for details) to the area form (scattering cross sections of acoustic targets):

$$C_{Fi} = 1.26 \cdot 10^6 \cdot L^{-2}$$

where  $L$  is total length in 1 cm length group  $i$  and  $C_{Fi}$  ( $\text{m}^{-2}$ ) is the reciprocal back scattering strength, or so-called fish conversion factor.

In order to split and convert the allocated  $s_A$ -values ( $\text{m}^2/\text{NM}^2$ ) to fish densities (numbers per length group per  $\text{NM}^2$ ), the following formula was used:

$$\rho_i = S_A \cdot \frac{p_i}{\sum_{i=1}^n \frac{p_i}{C_{Fi}}}$$

where

$\rho_i$  = density of fish in length group  $i$

$s_A$  = mean integrator value

$p_i$  = proportion of fish in length group  $i$

$\sum_{i=1}^n \frac{p_i}{C_{Fi}}$  = the relative back scattering cross section ( $\text{m}^2$ ) of the length frequency

sample of the target species, and

$C_{fi}$  = reciprocal back scattering cross section ( $\sigma_{bs}^{-1}$ ) of a fish in length group  $i$ .

The integrator outputs were split in fish groups using a combination of behaviour pattern as deduced from echo diagrams, the BEI analysis and catch composition as described below. The following groups were used for Mauritania: 1) sardinellas, 2) horse mackerels, 3) carangids and associated species, and 4) demersal fish.

The above equations show that the conversion from  $s_A$ -values to number of fish is dependent on the length composition of the fish. It is therefore important to get representative length distributions from the stock in the whole distribution area.

When the size classes (of e.g. young fish and older fish) are well mixed, the various length distributions can be pooled together with equal importance. Otherwise, when the size classes are segregated, the total distribution area has to be post-stratified, according to the length distributions, and separate estimates are made for the regions containing fish with equal size.

A systematic approach to a) divide the  $s_A$ -value between species in a category of fish (e.g. *Sardinella aurita* and *S. maderensis*) and b) produce pooled length distributions of a target species for use in the above equation and c) calculate the biomass estimates for a region, is obtained through the following procedure:

- The samples of the species in the category (e.g. sardinellas) are respectively pooled together with equal importance (normalized). A sample of 60 flat sardinella in one sample will have equal importance to 30 fish in another sample and not the double weight in accordance with the number of fish in the sample.
- The mean back scattering strength ( $\rho/s_A$ ) of each length frequency distribution of the target species is calculated and summed. This is automatically done if the length distributions are punched into an Excel spreadsheet prepared for the estimation of the abundance of fish (made available onboard “Dr. Fridtjof Nansen”).
- The mean  $s_A$ -value allocated to the category of fish in the region is divided between the species in the same ratio as their relative contribution to the mean back scattering strength of the length groups in the sample (also automatically done in the Excel spreadsheet given that the  $s_A$ -value for the region is punched into the sheet).
- The pooled length distribution is used, together with the mean  $s_A$ -value, to calculate the density (numbers per square NM) by length groups and species, using the above formula. The total number by length group in the area is obtained by multiplying each number by the area. (This is done in the Excel spreadsheet, given that the area of the region is punched into the sheet).
- The numbers are converted to biomass using the estimated weight at length. (Done in the Excel sheet if the condition factor is punched).

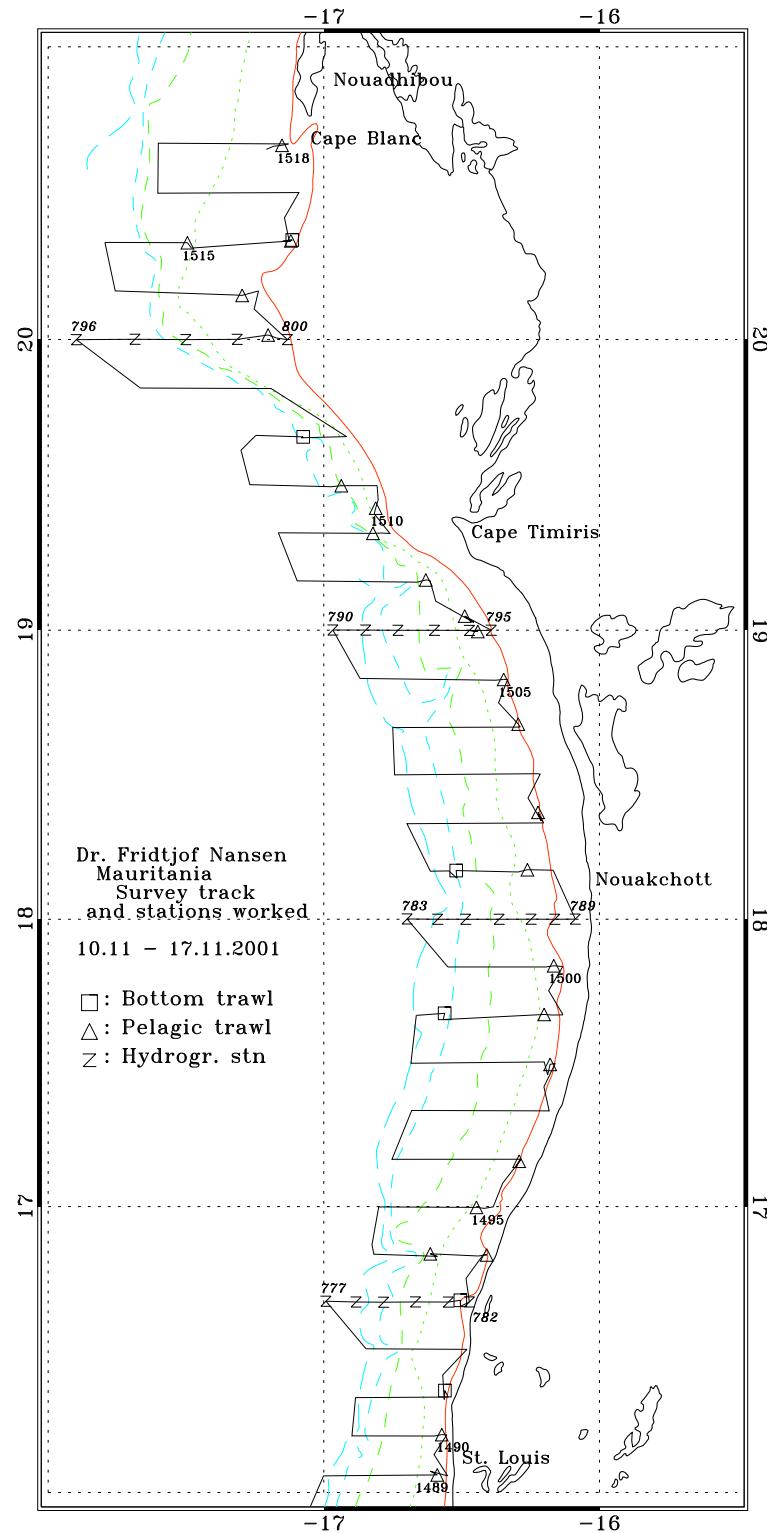

Figure 1 Course track and fishing and hydrographic stations

## CHAPTER 2 SURVEY RESULTS

---

### 2.1 Weather conditions and hydrography

#### *Wind conditions*

Distribution of wind speed and direction recorded along the survey track is presented in Figure 2. The predominant wind direction was from north. The wind velocities were uniform along this whole coastline region with average speed 20 m/s.

#### *Hydrography*

Figure 3 shows the distribution of sea surface temperature along the survey track. The temperature was significantly higher this year than in previous years. The general pattern south of Cape Timiris was a temperature of 25-27 °C off shore, decreasing to 22-24 °C inshore.

North of Cape Timiris to Cape Blanc, the distribution of sea surface temperature is affected by the persistence of the upwelling waters from the north with temperatures <19 °C off Cape Blanc.

Figure 4 shows the distribution of temperature, salinity and oxygen in the five profiles.

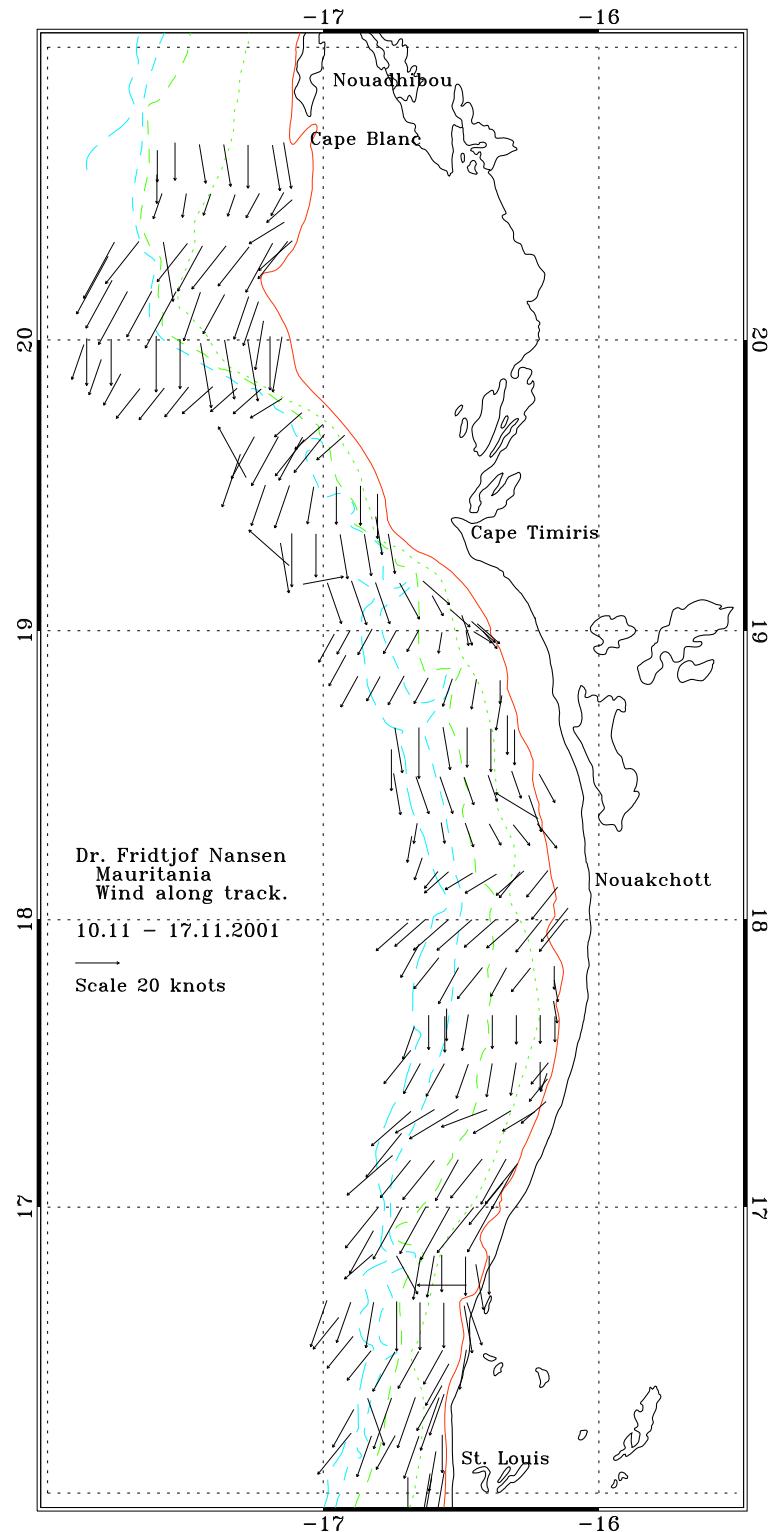

Figure 2 Wind conditions along the survey track.

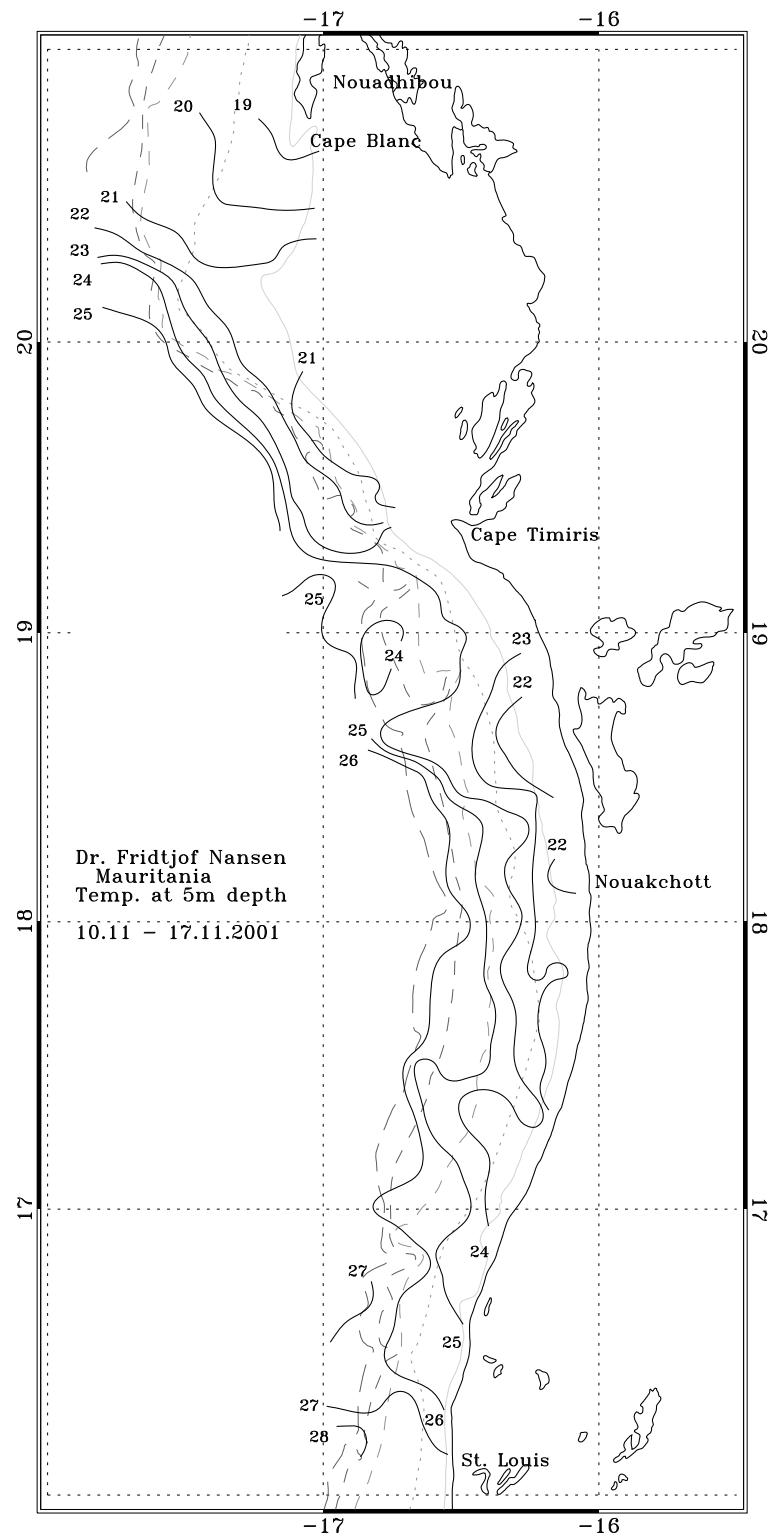

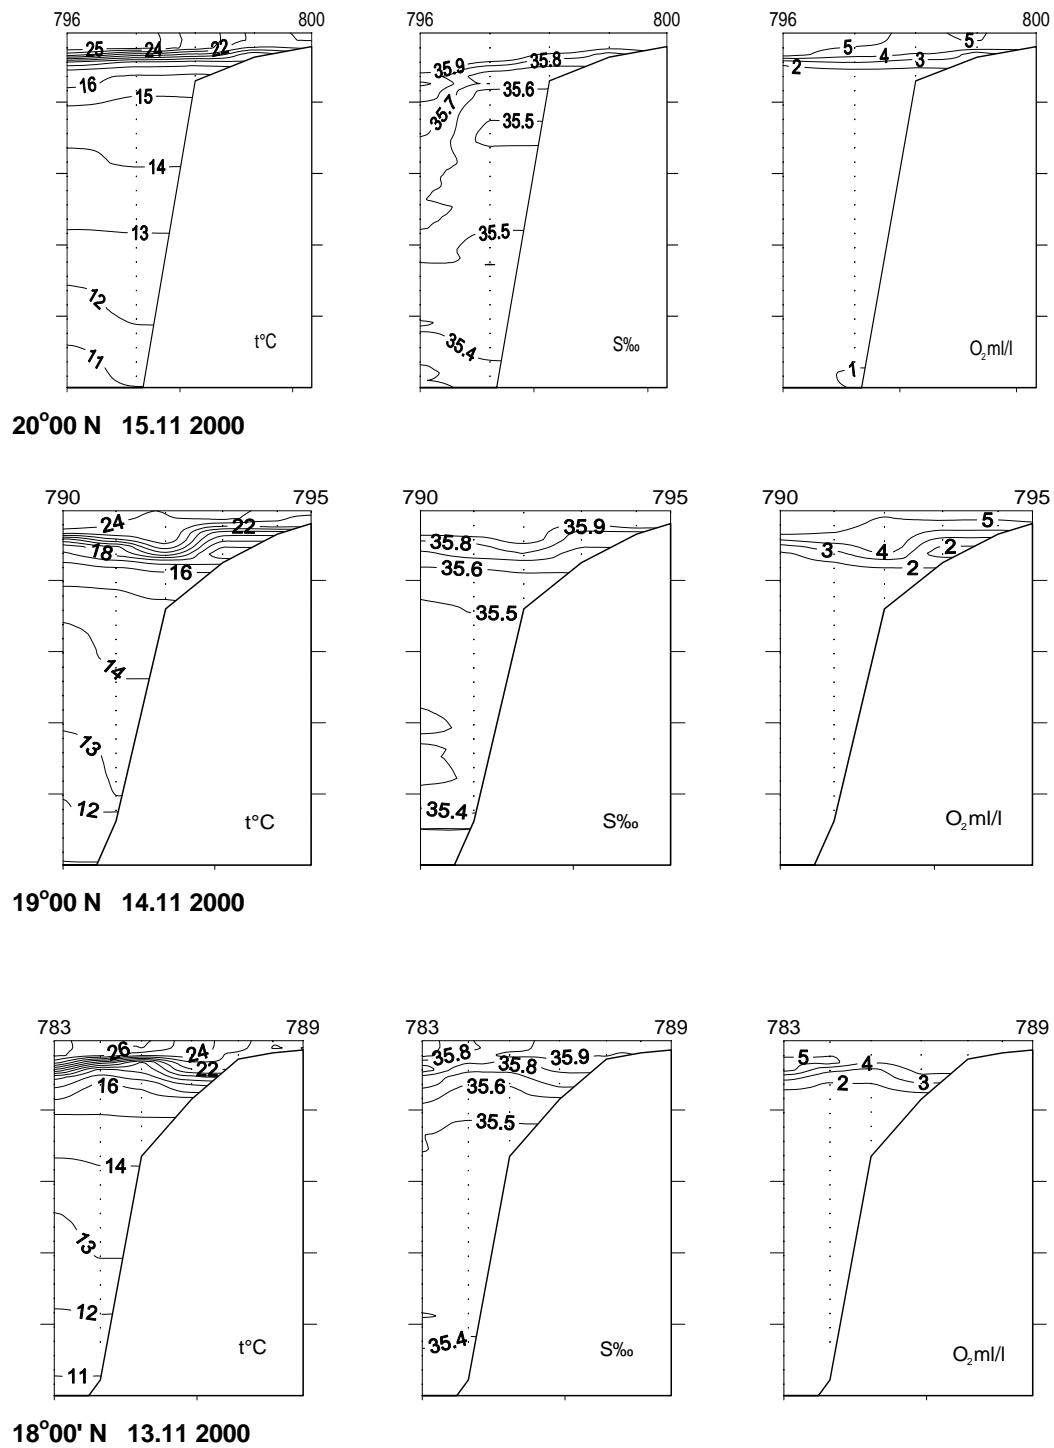

Figure 3 Sea surface temperature.

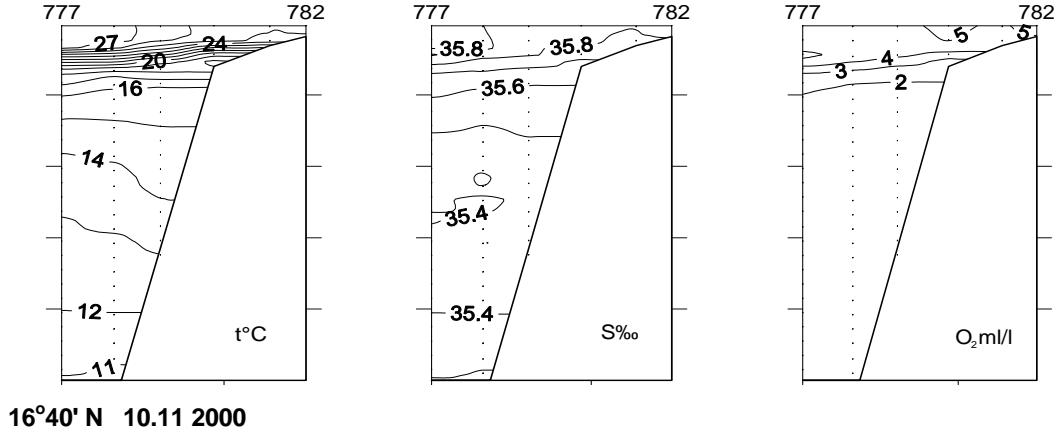

Figure 4. continued.

## 2.2 Pelagic fish on the shelf from St. Louis to Cape Timiris

Figures 5 shows the distribution of sardinellas on the shelf of Mauritania.

Sardinellas were found over the inner shelf in a nearly continuous belt along the coast from about 16°20'N to about 19°10'N, see Figure 5. In an area off Nouakchott and about 15 NM to north and south, no sardinella were found. Particularly dense school areas were located between about 16°20'N, at 17°30' N, and at about 19°00'N.

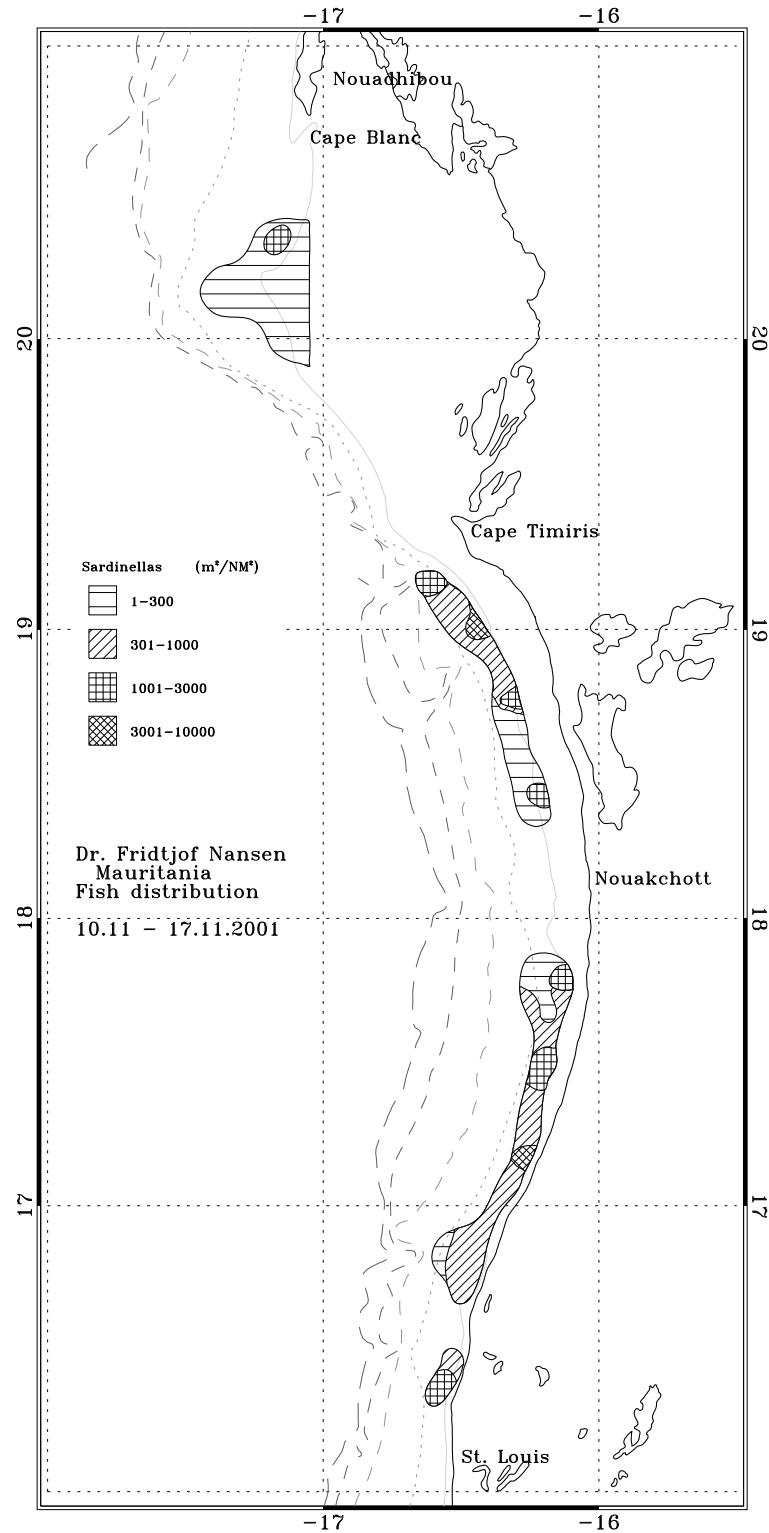

Figure 5 Distribution of sardinellas.

The samples showed sardinellas of varying size, the round sardinella south of Cape Timiris with modal lengths of 26 and 36 cm, while the flat sardinella had modal lengths of 11, 16, 27 and 33 cm. The size composition of the estimates is shown in Annex III, and the stock length composition by numbers and weight in Annex IV. The total biomass of sardinellas in the area was estimated at 200 000 tonnes, Table 1, of which flat sardinella dominated by 72 %.

Table 1. Biomass estimates (1000 tonnes) of pelagic fish, St. Louis to Cape Timiris.

Flat sardinella	Round sardinella	Horse mackerels	Other Carangids etc.
145	55	60	117

The distribution of horse mackerels is shown in Figure 6. Horse mackerels occurred in two main concentrations with rather low densities; one between 16°50'N - 17°10'N, and another between 18°20'N and 18°50'N. In addition, a few smaller concentrations were found. The densest concentrations in the main aggregations were found at about 17°00'N. The main aggregations were found at the edge of the shelf, and at daytime the fish were found close to the bottom at depths around 50-120 m. The biomass was estimated at 60 000 tonnes. The horse mackerels were only false scad, *Decapterus ronchus*.

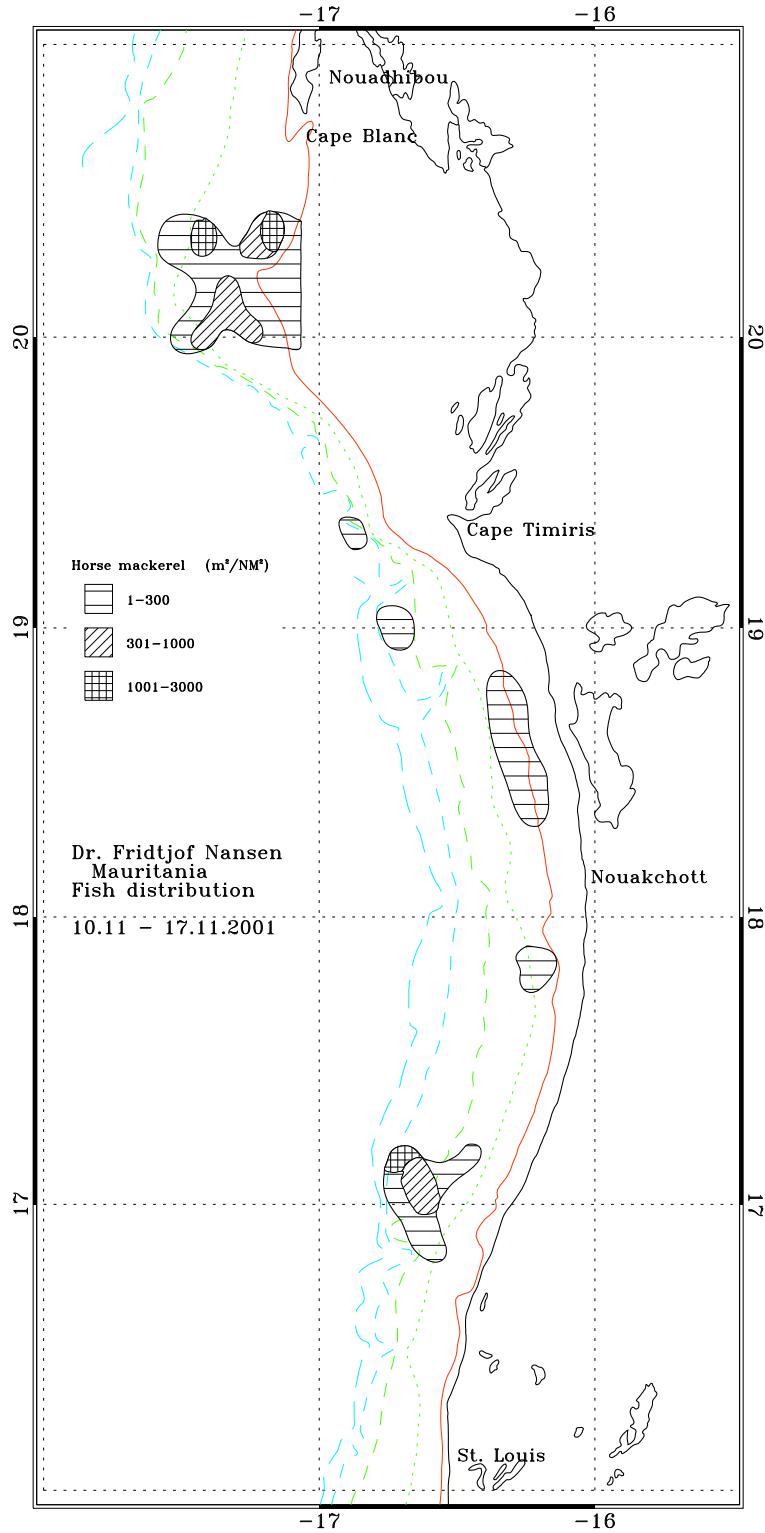

Figure 6 Distribution of horse mackerels.

Four modal lengths were observed in the total length distribution of *Decapterus ronchus*, namely 14, 18, 27 and 32 cm. The biomass was estimated at 60 000 tonnes, Table 1. The size composition of false scad is shown in Annex III, and the stock length composition by numbers and weight in Annex IV.

Figure 7 shows the distribution of the other carangids and associated species, which took the form of a continuous belt of various densities on the entire shelf, except for a small area some 20 NM south of Nouakchott, where no carangids were found. The total biomass was estimated at 117 000 tonnes. The samples from the distributional areas consisted of bumper, West African Spanish mackerel, Atlantic bonito, pompano with small amounts of barracudas.

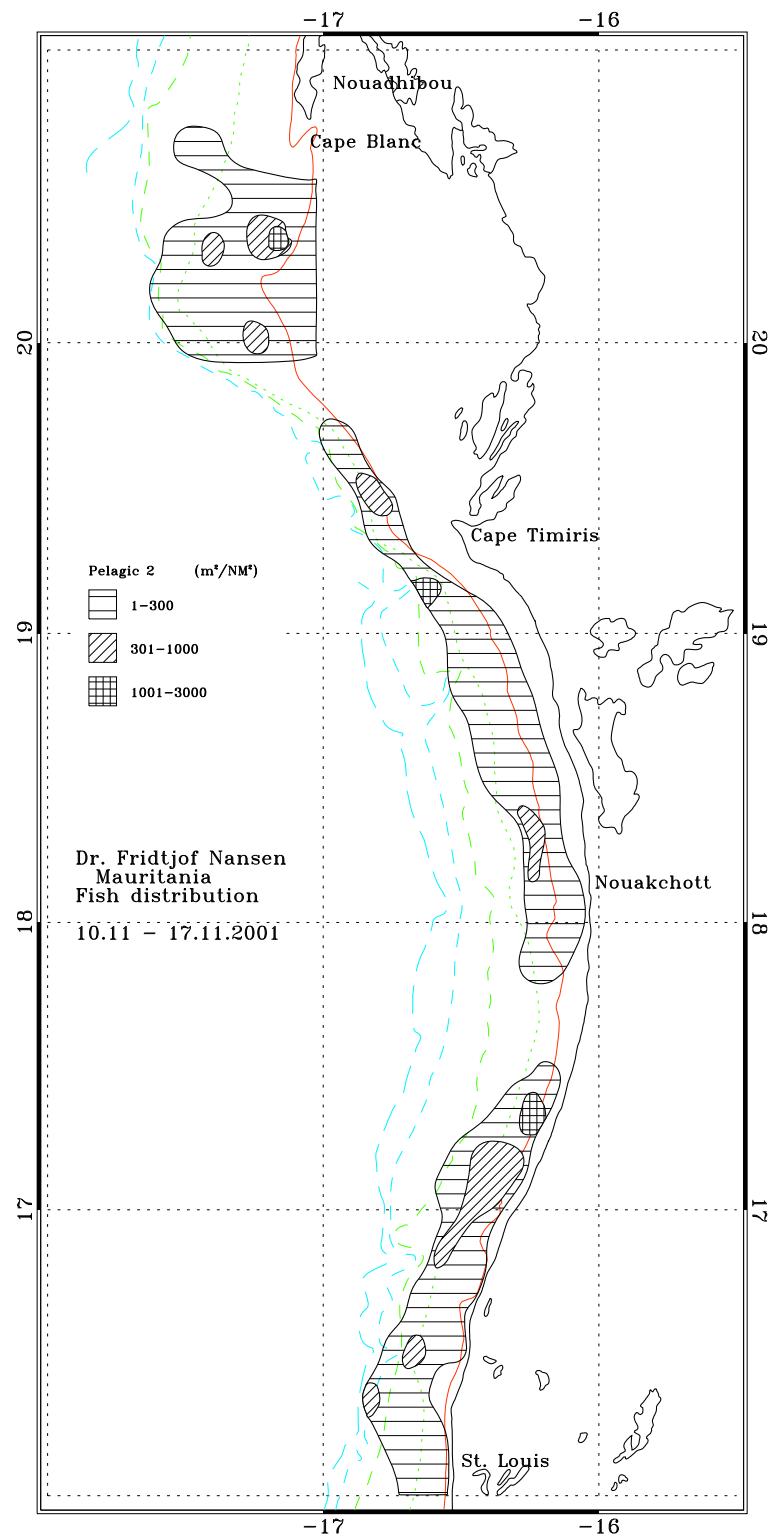

Figure 7 Distribution of carangids and associated species.

### 2.3 Pelagic fish on the shelf from Cape Timiris to Cape Blanc

Aggregations of juvenile fish are often found in the area between Cape Timiris and Cape Blanc, and this year, sardinella, horse mackerels and anchovy were present.

However, the estimate of small fish in the area must be regarded as uncertain and low because the area, Banc d'Arguin cannot be covered by the vessel. It is believed that a lot of juvenile fish is distributed there.

Round sardinella were found in an aggregation of schools between 20°00'N and 20°25'N, Figure 5. The concentrations were not very dense and the estimate was thus, only some 26 000 tonnes, Table 2. The modal lengths of the sardinella were 9, 15, 18 and 21 cm. It is believed that the coverage of sardinella in this area is not complete as there may be fish in the shallow waters of Banc d'Arguin.

Horse mackerel were recorded in an area between 20°00'N and 20°25'N, Figure 6. The aggregations consisted of both *Trachurus trecae* and *Decapterus ronchus*, estimated at 4 000 and 110 000 tonnes respectively (Table 2). The modal lengths of *Trachurus trecae* were 7, and 12 cm, while the medium size of the false scad, *Decapterus ronchus* were 14, 18, 23 and 28 cm.

Some anchovy were present in the catches on the northern part of the shelf, off Cap Blanc. And a few anchovy schools could be identified on the echograms. These were estimated at a biomass 9 000 tonnes with a modal length 8 cm.

The carangids and associated species were found in two main concentrations, one from Cape Timiris and some 30 NM northwards along the shelf, and the other, on the shelf from about 20°00'N to about 20°40'N, Figure 7. The concentrations were estimated at 75 000 tonnes. The catches of this group consisted mainly of *Trichiurus lepturus*, *Scomberomorus tritor*, and bluefish, *Pomatomus saltatrix*.

Table 2. Biomass estimates (1000 tonnes) of pelagic fish, Cape Timiris – Cape Blanc.

## **CHAPTER 3      OVERVIEW AND SUMMARY OF RESULTS**

---

The survey was conducted successfully in the period 10 to 17 November with a course track of 1400 NM and 30 fishing stations, Figure 1.

The hydrographical data show that the temperature is higher than the long-term mean.

Mainly adult sardinella were found between St. Louis and Cape Timiris, Figure 5. Horse mackerels were found in low densities in three main areas, the largest one north of Cape Timiris, Figure 6. Carangids (not including horse mackerel) and associated species occurred in low densities all along the shelf, with patches of high-density areas, Figure 7.

The total biomass of sardinella was estimated at 227 000 tonnes (64% flat and 36% round sardinella), that of horse mackerels at 174 000 tonnes and that of the carangids and associated species at 192 000 tonnes, see Table 3.

Table 3 Summary of biomass estimates (1 000 tonnes) of pelagic fish, Mauritania.

	Flat sardinella	Round sardinella	Horse mackerel	Carangids etc.
St. Louis-Cape Timiris	145	55	60	117
Cape Timiris-Cape Blanc	-	27	114	75
Total	145	82	174	192

Table 3 lists biomass estimates of sardinella and carangids and associated species from previous 'Dr Fridtjof Nansen' surveys of this shelf region. Compared earlier November-December surveys the estimate of 227 000 tonnes of sardinella from the current survey is the lowest on record since 1995. The carangid estimate (including horse mackerels) of 366 000 tonnes is also low when comparing with the available time series.

## **Annex II Instruments and fishing gear used**

The Simrad EK-500, 38kHz echo scientific sounder was used during the survey for fish abundance estimation. The Bergen Echo Integrator system (BEI) logging the echogram raw data from the sounder, was used to scrutinize the acoustic records, and to allocate integrator data to fish species. All raw data was stored to tape, and a backup of the database of scrutinized data, stored. The details of the settings of the 38kHz were as follows:

<b>Transceiver-1 menu</b>	Transducer depth	5.5 - 7.5 m
	Absorbtion coeff.	10 dB/km
	Pulse length	medium (1ms)
	Bandwidth	wide
	Max power	2000 Watt
	2-way beam angle	-21.0 dB
	SV transducer gain	27.16 dB
	TS transducer gain	27.26 dB
	Angle sensitivity	21.9
	3 dB beamwidth Along.	7.1°
	3 dB beamwidth Athw.	6.9°
	Alongship offset	0.07°
	Athwardship offset	0.03°
<b>Display menu</b>	Echogram	1
	Bottom range	10 m
	Bottom range start	9 m
	TVG	20 log R
	Sv colour min	-67 dB
	TS Colour minimum	-60 dB
<b>Printer- menu</b>	Range	0 - 50 or 0 -100 m and 100 - 350m
	TVG	20 log R
	Sv colour min	-60 dB
<b>Bottom detection menu</b>	Minimum level	-40 dB

A calibration experiment using a standard wolfram carbide sphere, performed off Langstrand, Walvis Bay 8 Sept. 2001 gave the following results:

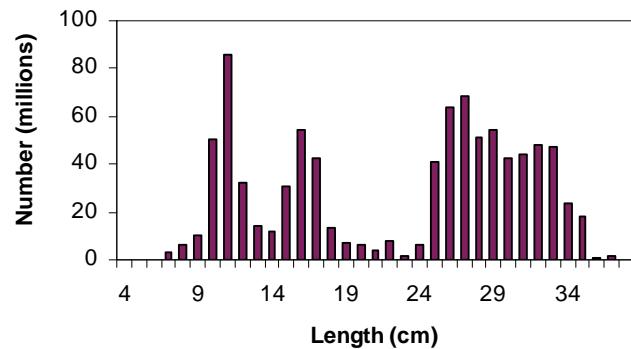

Sv Transducer gain 27.16 dB  
Ts Transducer gain 27.26 dB

### **Fishing gear**

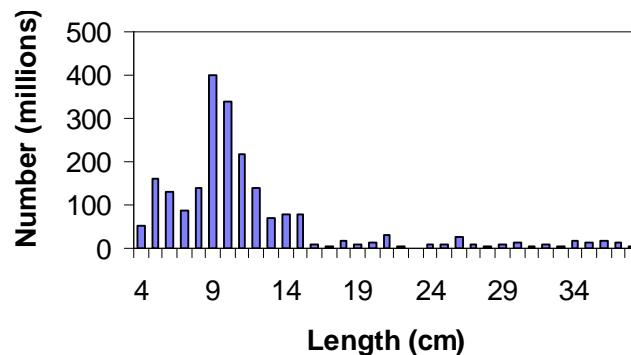

The vessel has two different sized "Åkrahamn" pelagic trawls and one "Gisund super" bottom trawl. For all trawls, the Tyborøn, 7.8m<sup>2</sup> (1670 kg) trawl doors were used.

### ANNEX III Pooled length distribution by species and regions

**St. Louis - Cape Blanc**  
*Sardinella maderensis*

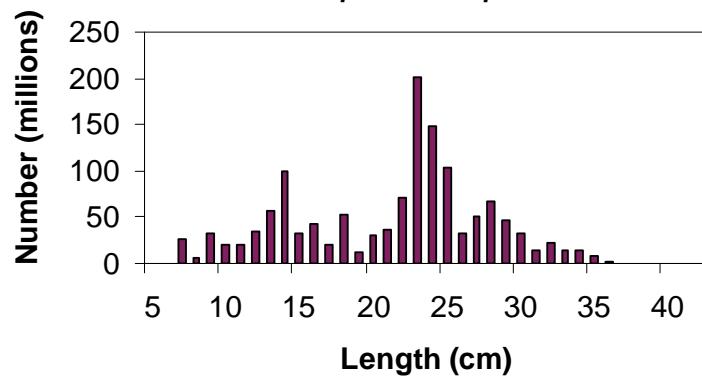

**St. Louis - Cape Blanc**

## CHAPTER 1 INTRODUCTION

---

### 1.1 Survey objectives

The specific objectives for the survey in Morocco were, as for the previous surveys:

- To map the distribution and estimate the biomass of the main small pelagic fish species using hydroacoustic methods. The species of interest were: sardine *Sardina pilchardus*, sardinellas *Sardinella aurita*, *S. maderensis*, chub mackerel *Scomber japonicus*, horse mackerel *Trachurus trachurus*, *T. trecae*, and anchovy *Engraulis encrasicolus*.
- To identify acoustic targets by midwater and bottom trawl sampling and process the catches by recording weight and number by species. For the target species, length frequencies are taken to describe the size distribution.
- As a pilot project: to collect otolithes of sardine and read these during the survey. (This objective was not realized, as personnel for reading otolithes were not available at departure.)
- To sample standard hydrographical transects for temperature, salinity and oxygen off Cape Blanc, Dakhla, Cape Bojador, Cape Juby, Cape Dra and Cape Ghir.
- To intercalibrate with the R/V *Al Amir Moulay Abdallah* in an area of sardine concentrations.

The time allocated for this part of the survey was 27 working days.

### 1.2 Participation

Members of the scientific teams were:

Institut National de Recherche Halieutiques, Morocco:

Mustafa CHBANI (team leader), Hamou HABOUZ, Lachen ABOUABELLAH, Rachid ZIANI, and Said SEMMOUMI

Centre National de Recherches Océanographiques et des Pêches, Mauritania: Cheik Tijane DIOP.

Institute of Marine Research, Norway (IMR):

Tore STRØMME (cruise leader), Marek OSTROWSKI (3-19 Dec.), Oddgeir ALVHEIM, Tore MØRK, and Thor Egil JOHANSSON.

### 1.3 Narrative

Figure 1 shows the cruise track and the stations worked during the survey. The vessel departed from Nouakchott on November 17, steaming north to Cape Blanc from where the sampling work started. The survey proceeded northwards with an acoustic sampling grid with a transect distance 10 nautical miles (NM) apart, covering the shelf and slope down until about 200 m bottom depth. The sardine in the Dakhla region had a more offshore distribution than usual and it was not necessary to resurvey the near-shore areas with a finer grid as on preceding surveys. The sampling continued north to Cape Juby where the survey was interrupted with a call at Las Palmas 1-4 December for refuelling and change of crew. The survey proceeded northwards from Cape Juby covering the inner shelf between Cape Juby and 30°N with a zigzag pattern during the day, while the outer shelf was covered during night time with a more open grid, (Figure 1b). At Cape Dra the vessel met the Moroccan research vessel '*Al Amir Moulay Abdallah*' for intercalibration work. The two vessels worked in tandem from Cape Dra to Agadir, continuing the standard acoustic survey. Off Agadir there was a stop for exchange of data and scientists. The survey proceeded northwards with a survey track perpendicular to the coast, transecting the whole shelf. The northern limit of the survey, off Safi, was reached on 11 December. The vessel then steamed south to the Tan Tan region. The shallow areas (20-50 m) between Cape Dra and Agadir were re-surveyed, as much fish here was located close to the surface during the initial and main coverage. The vessel called on Agadir on 15 December for a meeting with representatives from INRH, Casablanca, and for disembarking local scientist. The vessel arrived on Las Palmas 18 December.

Standard hydrographical sections were sampled at Cape Blanc, off Dakhla, at Cape Bojador, Cape Juby, Cape Dra, and Cape Ghir.

The weather was favourable during most of the survey, and it put no constraints on the sampling work.

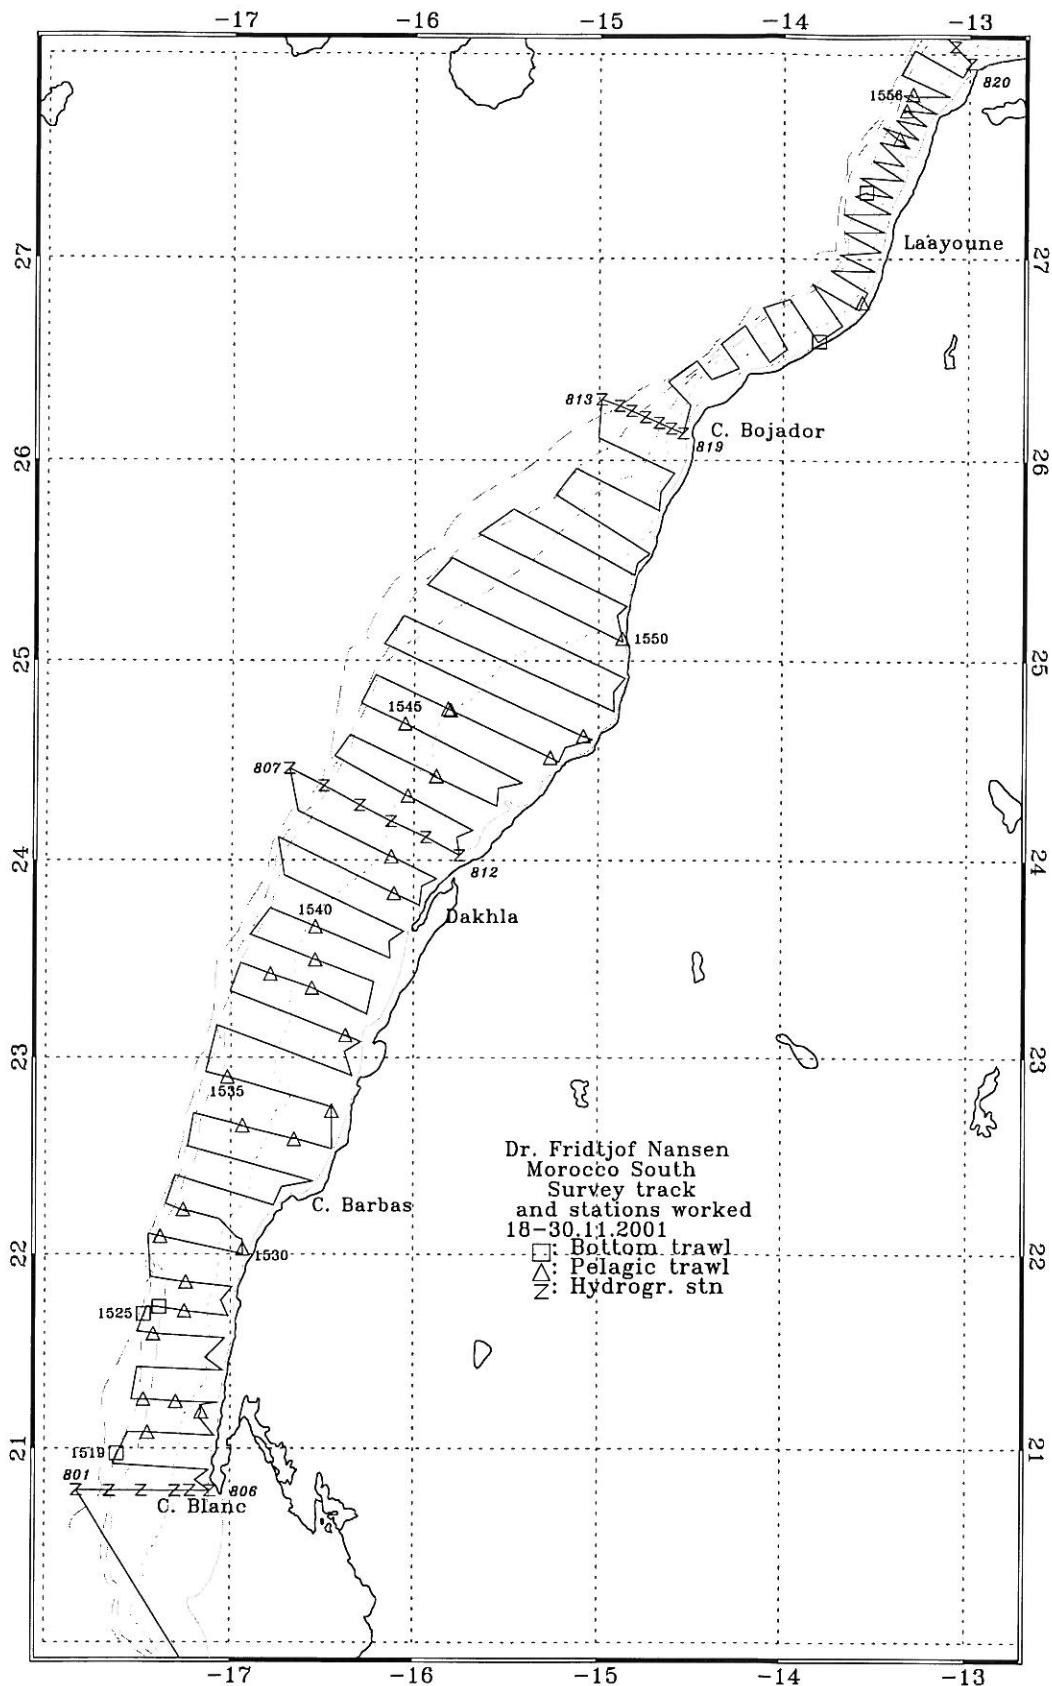

Figure 1a Course track with fishing and hydrographic stations, Cape Blanc to Cape Juby. Depth contours at 20 m, 50 m, 100 m, 200 m and 500 m are indicated.

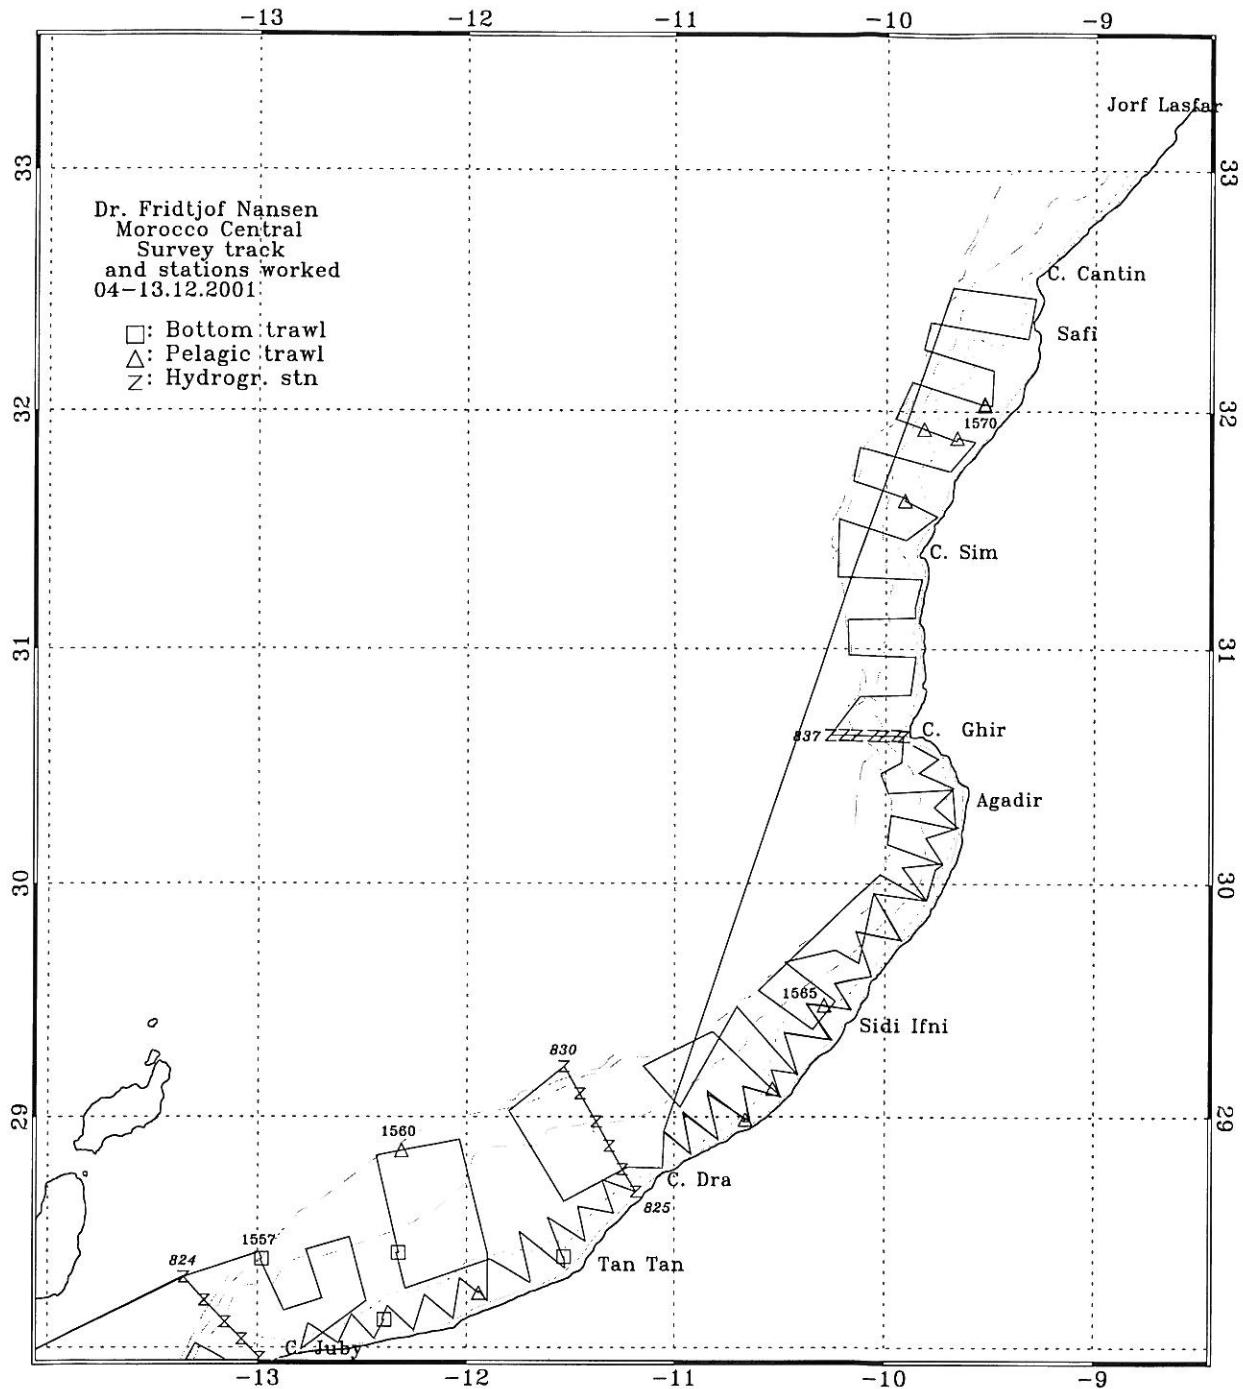

Figure 1b Course track with fishing and hydrographic stations, Cape Juby to Cape Cantin. Depth contours as in Fig. 1a.

## 1.4 Methods

The cruise followed the standard methods established for the regional surveys:

### *Environmental Data*

Meteorological observations including wind direction and speed, air temperature, solar radiation and sea surface temperature (SST) were automatically logged and recorded with position and bottom depth every nautical mile sailed using an Aanderaa meteorological station. CTD-stations were recorded at the standard hydrographic transects. A Seabird 911+ CTD probe was used to obtain vertical profiles of temperature, salinity and oxygen. Real time plotting and logging was done using the customised Seabird Seasave software installed on a PC. The profiles were in general taken down to a few meters above the bottom. In deep stations, however, data logging was interrupted at 500 m. Niskin bottles were triggered for water samples, one near the surface and one near the bottom, in order to calibrate the oxygen and salinity sensors. The water samples were analysed for dissolved oxygen using the Winkler method, and for salinity using a Guildline Portasal salinometer mod. 8410.

### *Biological Sampling*

Biological sampling of the fish was carried out using trawls. A pelagic trawl with floats was often used. A smaller pelagic trawl or the bottom trawl with floats was used for sampling the pelagic fish in very shallow waters (depth less than 25 m). Annex II gives a description of the instruments and the fishing gear used. All catches were sampled for composition by weight and numbers of each species caught. Species identification was based on the FAO Species Guides. Length frequency distributions, by total fish length in cm, of the selected target species were taken in all the stations where they were present. The complete records of fishing stations are shown in Annex I.

As a pilot study for a forthcoming regional project on age determination of sardine and sardinella, sardine otoliths were collected and preserved for later reading ashore. No personnel were available for reading the otoliths during the survey.

The following target groups were used for Morocco:

- 1) Sardine (European pilchard *Sardina pilchardus*),
- 2) Sardinellas (flat sardinella *Sardinella maderensis* and round sardinella *S. aurita*),
- 3) Anchovy (European anchovy *Engraulis encrasicolus*),

- 4) Horse mackerels (Atlantic horse mackerel *Trachurus trachurus*, Cunene horse mackerel *T. trecae* and also including false scad *Decapterus rhonchus*),
- 5) Mackerels (chub mackerel *Scomber japonicus*),
- 6) Other pelagic scombrids, carangids and associated species (such as *Auxis* sp., *Caranx* sp. and largehead hairtail *Trichiurus lepturus*), BEI group PEL2
- 7) Other demersal species (such as Sparidae, Haemulidae and Merluccidae).

#### *Acoustic Sampling*

A SIMRAD EK500 Echosounder was used and the echograms were stored on both paper and files. The acoustic biomass estimates were based on the integration technique. The Bergen Echo Integrator (BEI) was used for analysis and allocation of the integrated  $s_A$ -values (average area back scattering coefficient in  $m^2/NM$ ) to the individual specified target groups, usually by 5 NM intervals. Where bottom detection was poor and where fish schools were located very close to the bottom, the bottom echo was sealed off from the fish registrations by manual contouring. The splitting and allocation of the integrator outputs ( $s_A$ -values) was based on a combination of a visual scrutiny of species characteristics as deduced from echo diagrams, the BEI analysis, and the catch compositions.

In cases where the target category of fish contains more than one species (sardinellas and horse mackerels), the mean  $s_A$ -value allocated to the category is divided between the species in the same ratio as their relative contribution to the mean back scattering strength in the length frequency samples.

The following target strength (TS) function was applied to convert allocated  $s_A$ -values (average integrator value, or area back scattering coefficient for a given species or group of species in a specified area) to number of fish:

$$TS = 20 \log L - 72 \text{ dB} \quad (1)$$

which can be converted (see Toresen *et al.* 1998 for details) to the area form (scattering cross sections of acoustic targets):

$$C_{Fi} = 1.26 \cdot 10^6 \cdot L_i^{-2} \quad (2)$$

where  $L_i$  is total length in 1 cm length group  $i$  and  $C_{Fi}$  ( $m^{-2}$ ) is the reciprocal back scattering cross section, or so-called fish conversion factor. In order to split and convert the allocated  $s_A$ -values ( $m^2/NM^2$ ) to fish densities (numbers per length group per  $NM^2$ ), the following formula was used:

$$\rho_i = s_A \cdot \frac{p_i}{\sum_{i=1}^n \frac{p_i}{C_{Fi}}} \quad (3)$$

where  $\rho_i$  = density ( $n/NM^2$ ) of fish in length group  $i$   
 $s_A$  = mean integrator value ( $m^2/NM^2$ )  
 $p_i$  = proportion of fish in length group  $i$   
 $\sum_{i=1}^n \frac{p_i}{C_{Fi}}$  = the relative back scattering cross section ( $m^2$ ) of the length frequency sample of the target species, and  
 $C_{Fi}$  = reciprocal back scattering cross section ( $\Phi_{bs}^{-1}$ ) of a fish in length group  $i$

For TS= 20log L- be 72 the formula can further simplified into:

$$\rho_i = 1261217 * s_A \frac{n_i}{\sum_{i=\min}^{\max} n_i l_i^2} \quad (4)$$

where  $s_A$  = mean integrator value of a species within an aggregation area, in  $m^2/NM$

$n_i$  = frequency count of length group  $i$  in a pooled representative sample from the distribution area.

$l_i$  = mid length of fish in length group  $i$ .

The constant 1261217 incorporates the offset constant -72 in equation (1). For other TS relationships the equation constant becomes as in box. The table is presented to facilitate a recalculation in case more accurate TS measurements are provided in the future:

Using equation (4), the pooled length distribution is used together with the mean  $s_A$ -value to calculate the density by length groups for each observed area with fish aggregations. The total number, by length groups, in an area is obtained by multiplying the densities with the distribution area. Areas were calculated on the maps by using a digital planimeter (Tamaya Planix 7).

TS constant	Equation constant
-74	1998895
-73	1587779
-72	1261217
-71	1001821
-70	795774
-69	632106
-68	502099

The number of fish was converted to biomass by length group using the estimated weight at length from the length-weight relationship:

$$\bar{w} = \frac{cond}{100} * L^3 \quad (3)$$

The specific condition factors obtained from the samples and applied for this survey were: 0.82 for sardine, 0.94 for *S. aurita*, 0.97 for *S. maderensis* and 0.84 for horse mackerel.

Finally the total biomass estimate is obtained by summing the biomass by length group and areas within each sector of the survey.

Equations (1), (2) and (3) show that the conversion from  $s_A$ -value to number of fish is dependent on the length composition of the fish. In general there are many problems associated with getting representative length distributions when the various size classes mix with varying proportions between neighbouring stations. When the size classes are well and homogenously mixed in an area, the various length distributions are pooled together with equal importance. In areas where fish size-groups are well segregated, separate estimates are made for each group. Otherwise, when the size distribution varies from sample to sample, a weighting factor is applied that takes into account the density at the location. In most cases, the mean acoustic density at the location of the sample is the most representative index of this fish density.

For the estimation of the biomass of target group 3) carangids and associated species, an overall average length of 23 cm and a condition factor of 0.88 (to calculate mean weight of this length group) were applied.

A systematic approach to a) produce pooled length distributions of a target species for use in the above equation and b) calculate the biomass estimates for a region, are obtained through the following procedure:

- Each trawl station gets an integrator value as a density index for the sampling site.
- Representative length distributions are selected from all the collected samples of a fish aggregation.
- The mean back scattering strength of a fish in each of these length frequency distributions is calculated.
- The selected length distributions are then pooled using the ratio between the allocated  $s_A$ -value and the mean back scattering strength as the weighting factor. (If the size distribution is geographically uniform the three steps mentioned above can be skipped and the samples are pooled together with equal importance.)
- The pooled length distribution is used together with the mean  $s_A$ -value to calculate the biomass in numbers by length groups, for each area in the map, using formula (4) above. Numbers are converted to weight using the condition factor of the species. This can be calculated from the length samples where the total weight of the sample is recorded, or from individual biological samples.
- Biomass is calculated as the product of the density and the area of the aggregation, and finally the area-related biomass values in a region are summed together.

The necessary calculations are done in spreadsheets after the scientist has completed the two first steps in the above list manually.

All data on fishing stations and fish length sampling were made available to the participants from the local research institutes on diskettes.

## CHAPTER 2 SURVEY RESULTS

---

### 2.1 Hydrographic conditions

The weather conditions in the Northeast Atlantic during autumn and early winter are dominated by the southward migration of the trade wind system, resulting in the relaxation of the alongshore wind, responsible for driving coastal upwelling along the Moroccan coast. The results of the oceanographic observations conducted during the survey adhered to this general pattern, but also detected several notable departures from the typical winter conditions.

#### *Wind conditions*

The northeasterly, upwelling favorable winds persisted along the most of the southern part of the survey area, (Figure 2a). The daily mean wind velocities varied from 5 to 11 m/s. The notable exception was observed to the north of Cape Blanc where a day-lasting event of the unusually calm conditions was recorded, dominated by a westerly wind with velocity less than 2 m/s.

The wind conditions encountered in the northern part of the survey area (Figure 2b) displayed the two distinct wind patterns: from Cape Juby to Cape Ghir and from Cape Ghir to Cape Cantin. Between Cape Juby and Sidi Ifni, moderate northeasterly winds with average daily mean velocities of 6 m/s were dominant. However, also the stronger, small-scale wind reversals from SE with the velocity of 10 m/s were recorded inshore in this area. Between Sidi Ifni and Cape Cantin, the survey encountered a strong wind event blowing from the southern sectors (SSE to SSW). The average wind speed reached 11m/s, which was comparable to the wind velocity observed north of Dakhla.

#### *Sea surface temperature*

Distributions of sea surface temperature are depicted in Figure 3a for the southern region and in Figure 3b for the northern region, respectively. In the south, the SST the observations indicated for an occurrence of a warm temperature anomaly. The temperature in the shelf typically oscillated around 20°C. The cold-water signatures, which typically mark the location the perennial upwelling cells were absent (Dakhla) or reduced in strength (Cape Blanc). The only visible upwelling cell was observed more northwards, at 24°45'N, whereby it was marked by a drop in temperature below 18°C. On average, the SST values observed during this survey in the

south were about 2 degrees higher from those recorded during the previous winter survey in December 2000.

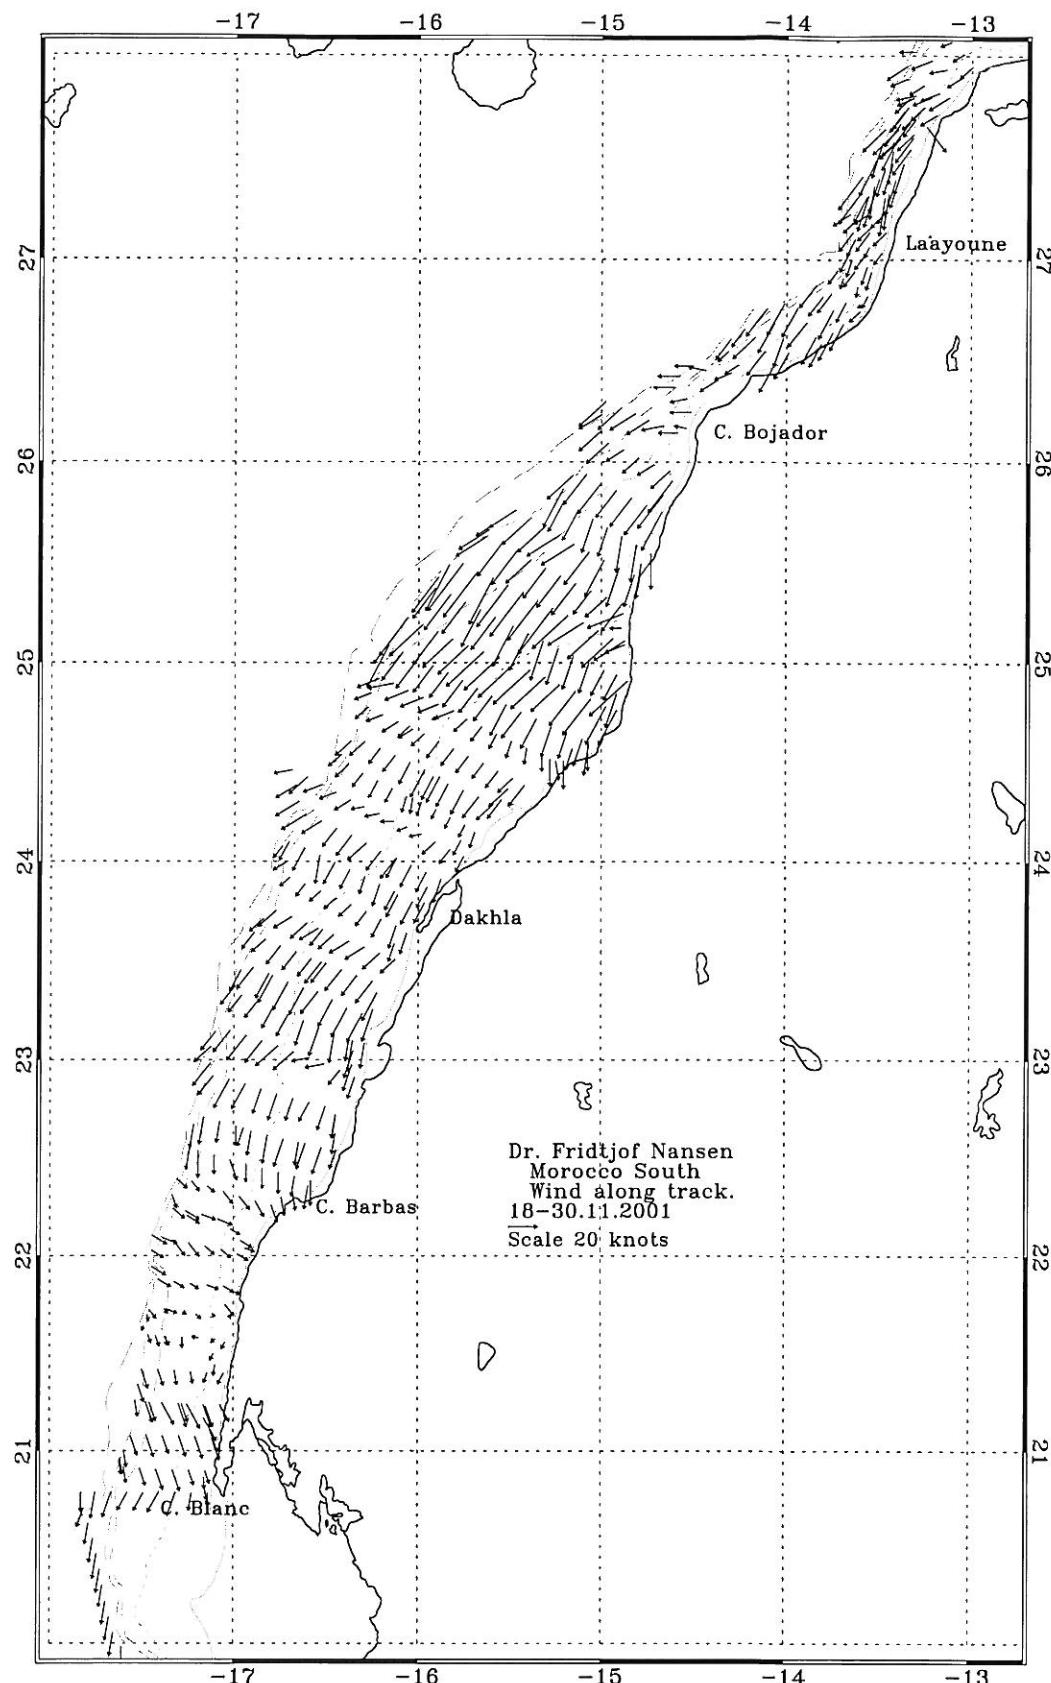

Figure 2a Wind conditions along the survey, Cape Blanc to Cape Juby. Depth contours as in Fig. 1a.

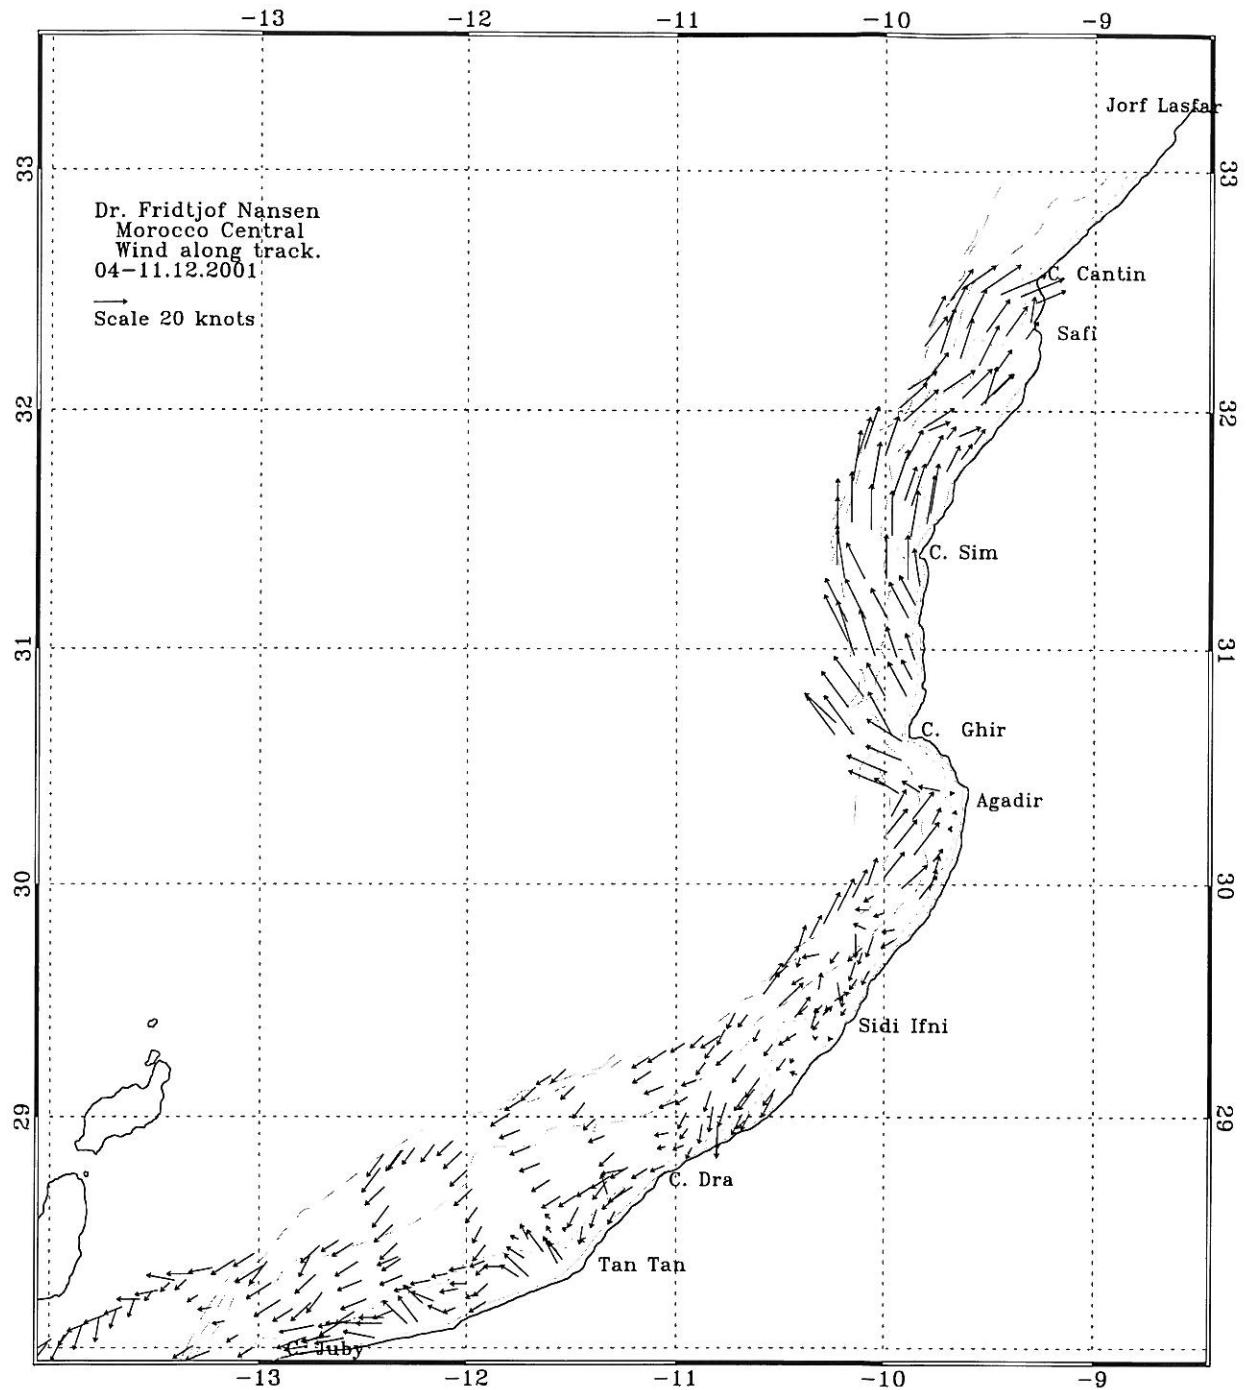

Figure 2b Wind conditions along the survey, Cape Juby to Cape Cantin. Depth contours as in Fig. 1a.

In the northern part of the survey area (Figure 3b), the SST distribution revealed the presence of the colder water belts ( $T < 18^\circ$ ), located inshore and with broad alongshore extent between Cape Juby and Sidi Ifni, off Agadir and between Cape Sim and Cape Cantin. This distribution pattern reflected the typical seasonal condition for this region, recorded also during previous winter surveys with

Dr. Fridtjof Nansen. Thus, the 2001 observation in the north did not detected, contrary to the SST observed in the south, a significant departure from the long-term normal conditions.

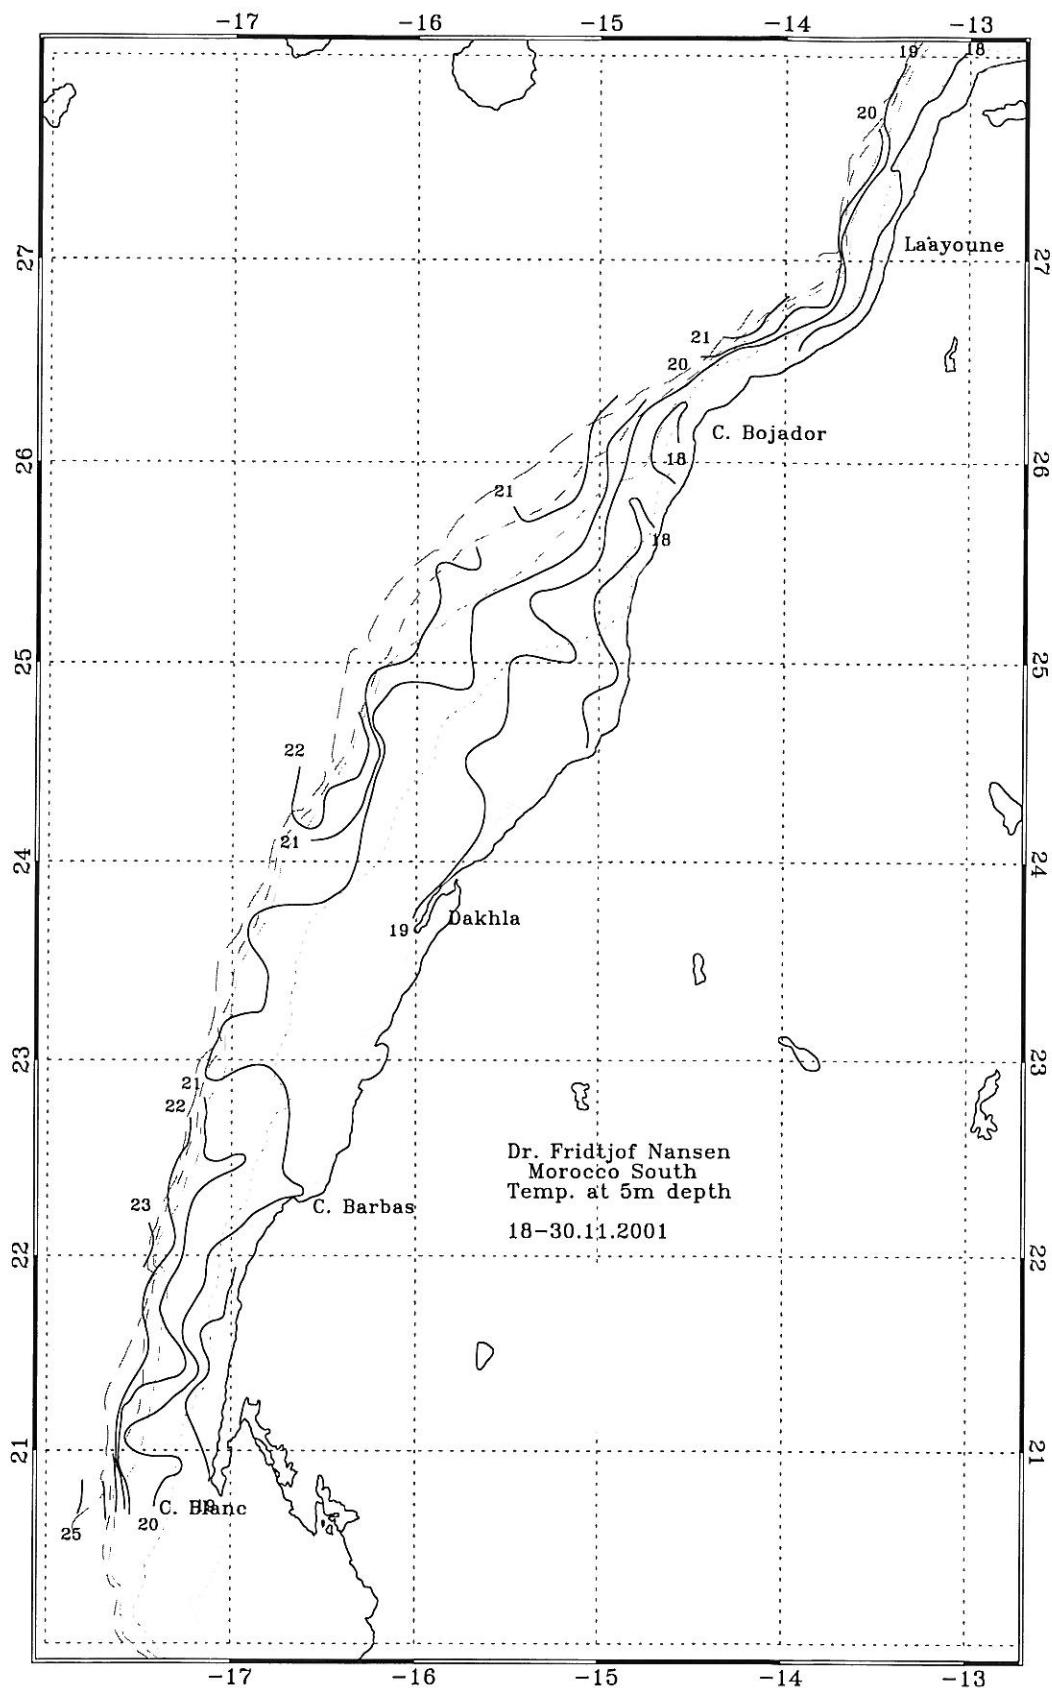

Figure 3a Sea surface temperature (at 5m depth), Cape Blanc to Cape Juby. Depth contours as in Fig. 1a.

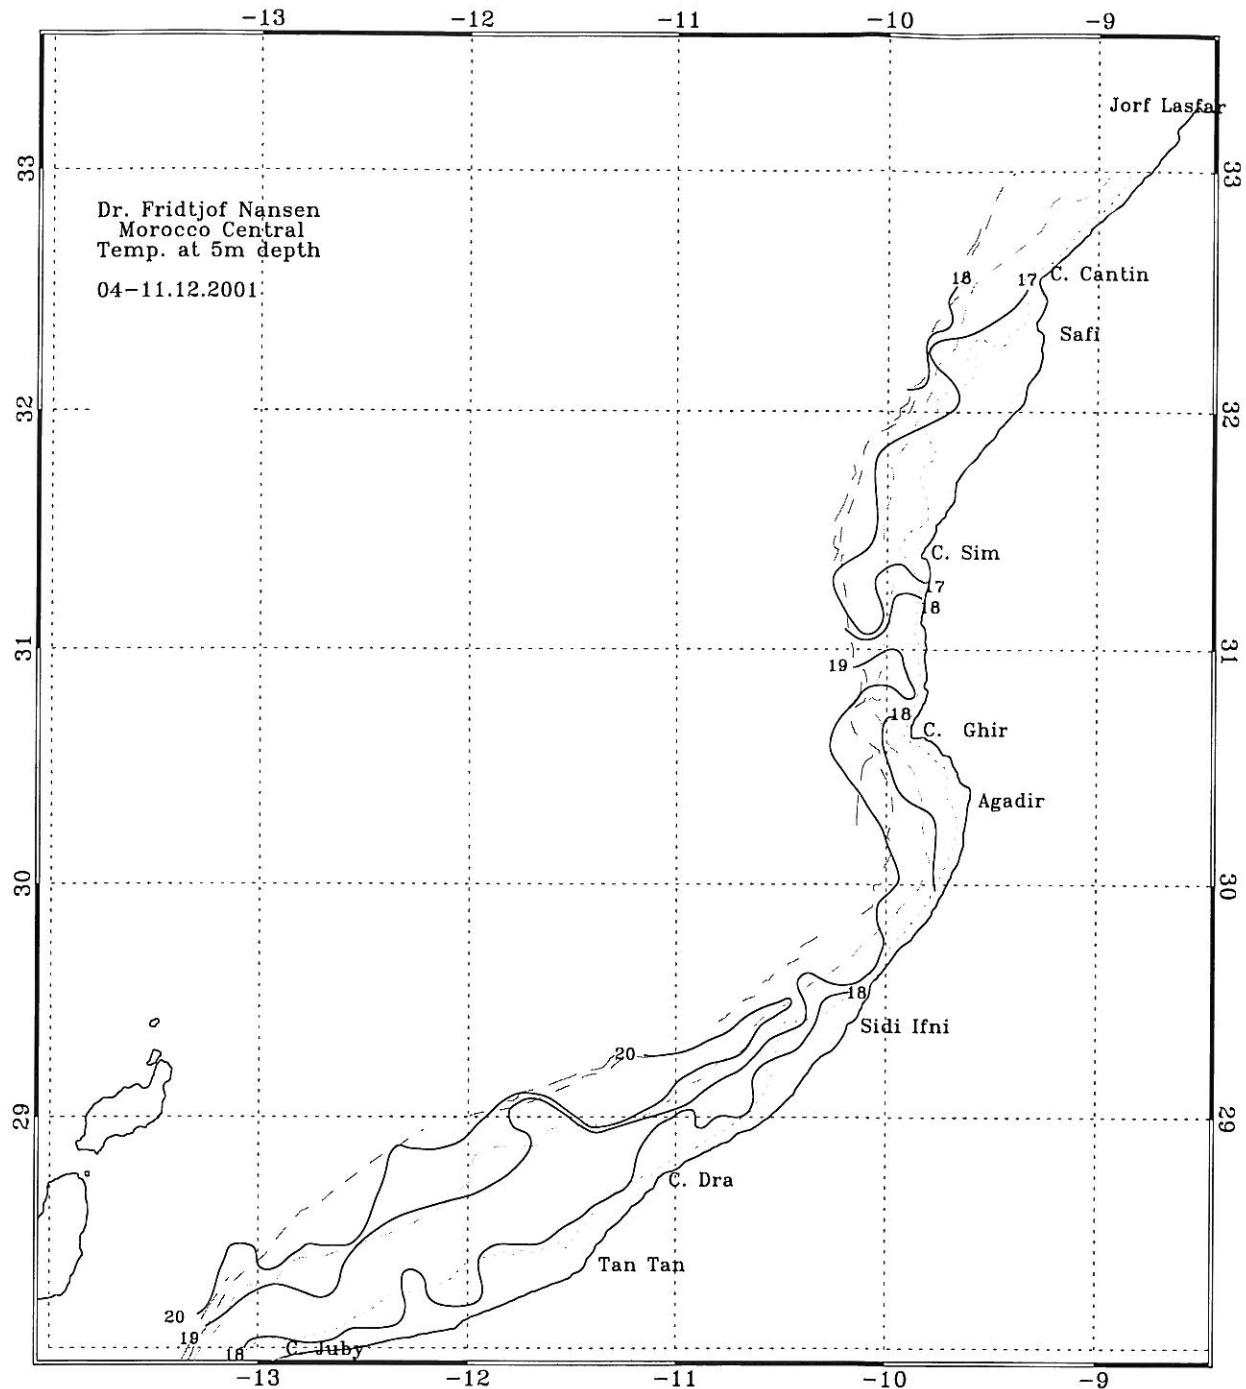

Figure 3b Sea surface temperature (at 5m depth), Cape Juby to Cape Cantin. Depth contours as in Fig. 1a.

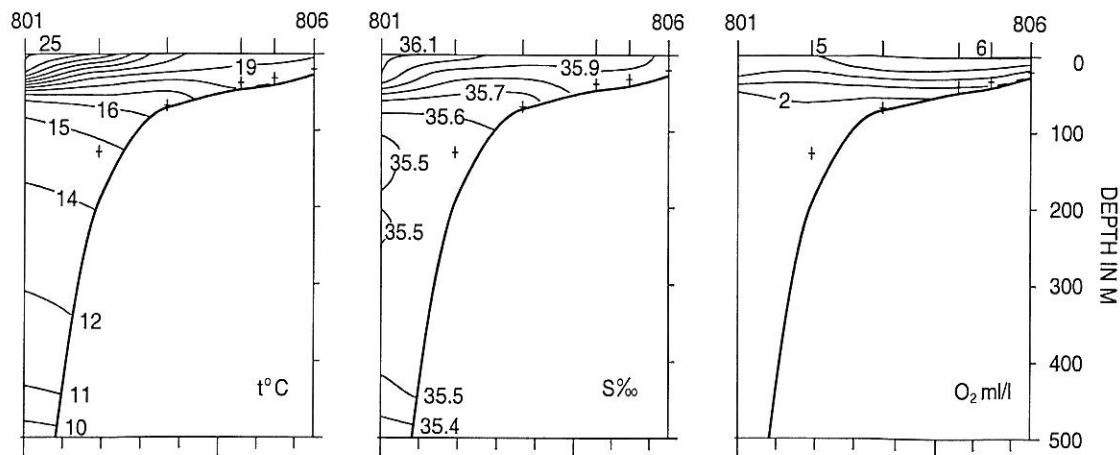

#### *Vertical distribution of seawater properties*

Vertical stratification of the water column was observed along the six sections, depicted in Figure 4. The locations of the sections are shown in Figure 1a and 1b.

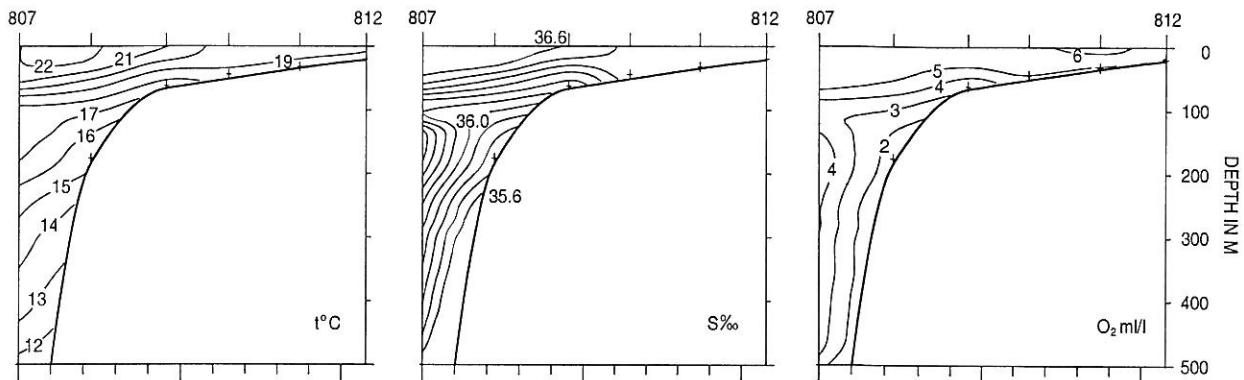

In the southern portion of the survey area, between Cape Blanc and Dakhla, hydrographic conditions at the surface were dominated by the two major water masses: (1) the warm and high-salinity water of the North Atlantic and Mediterranean origin, surrounding the shelf from the north and the west; and (2) also warm, but less saline and with significantly shallower pycnocline, the water of the Tropical Atlantic origin, advancing along the shelf from the south. The conditions typical to the Tropical Atlantic clearly dominated the T, S and O distributions along the Cape Blanc section (Figure 4). These were manifested by a strong stratification, with the top mixed layer and a shallow pycnocline at the depth of 30 m. Across the pycnocline temperature dropped below 19°C, salinity dropped below 35.9 and oxygen decreased from 5 to 3 ml/l. However, the gradual, simultaneous increase in temperature and salinity along the section towards the west indicated an increasing influence of the surface waters of the North Atlantic origin. On the offshore end of the section, the warm and high-salinity core of the southwestwards flowing Canary Current, the origin of this water mass, was clearly detectable. To the north, off Dakhla section, the surface waters of the North Atlantic origin dominated the hydrography on the shelf. The Canary current surface water was located at about 50 - 55 NM offshore, while its properties:  $T > 19^{\circ}\text{C}$ ,  $S > 36.3$  radiated into the inshore areas. Typically, vertical stratification during winter off Dakhla, due to upwelling, would tend to disappear inshore whereas the horizontal density gradient would be strong across the whole shelf. During this survey, however, the vertical stratification was well marked and the horizontal gradient was weak. Such pattern, apparently coupled to the observed relaxation of wind in this region, manifested a rather atypical reduction in upwelling intensity during the time of the survey.

The hydrographic conditions off Cape Bojador were entirely coupled to the Canary Current system. In this location, the steep continental slope and narrow shelf zone cause the core of the Canary Current to flow within the 20 NM from the coastline, injecting the high temperature and salinity water to the inshore areas. Still, during typical winters, a ribbon of colder water, brought to surface by upwelling would be typically detectable within the 5 to 10 NM from the coastline. During the 2001 survey, the presence of the upwelled water inshore was not clearly detected.

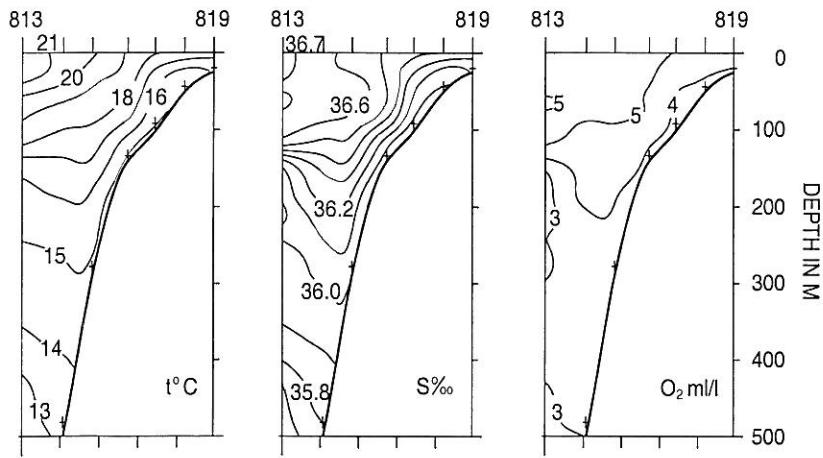

The hydrographic conditions observed on the sections located in the northern part of the survey area (Cape Juby, Cape Dra and Cape Ghir) were less anomalous with respect to the typical winter conditions (Figure 4). While the temperature and salinity of the water masses offshore were higher than usual, the inshore waters remained in the typical range for winters ( $T > 17$  and  $< 18^{\circ}\text{C}$ , and  $S = 36.3$ ), most probably due to the persisting upwelling induced uplift of the north Atlantic central water mass to the coastal areas. One exception was observed inshore off the Cape Ghir section, where the subsurface isotherms of less than 17°C were gently downsloping towards the coastline, manifesting thus a weak downwelling process. The occurrence of a downwelling process at this location was consistent with the expected effect of the observed southeasterly wind event in this area.

Cape Blanc – 19.11.2001

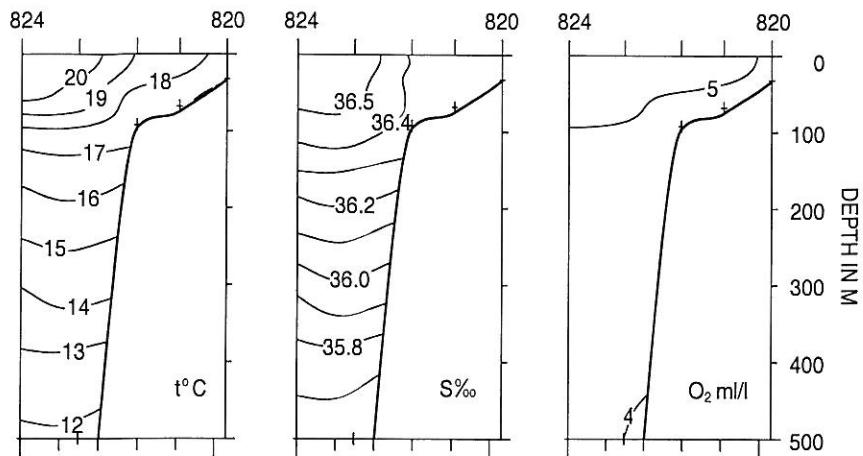

Dakhla – 24.11.2001

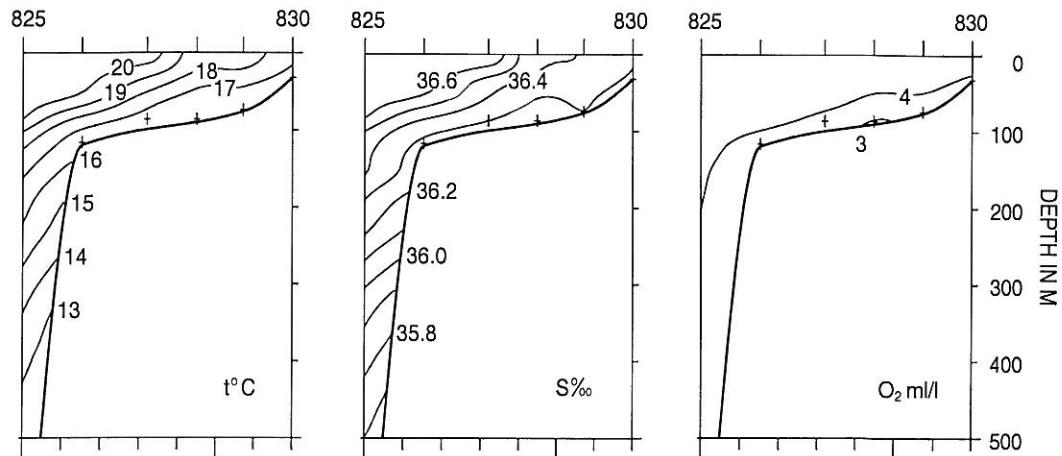

Cape Bojador – 28.11.2001

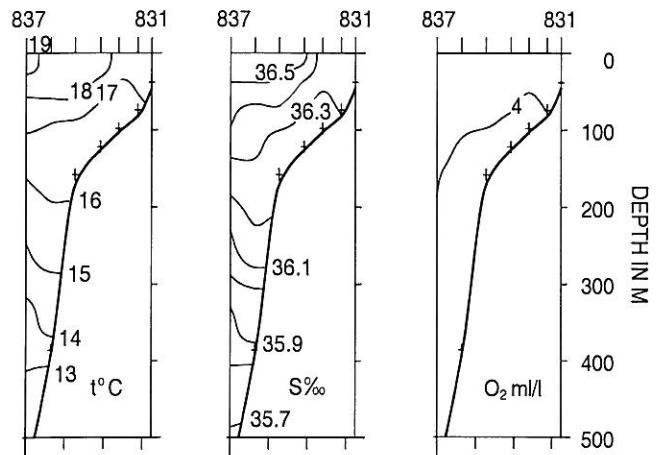

Figure 4 Hydrographic sections with distribution of temperature, salinity and oxygen.

Cape Juby – 30.11.2001

Cape Dra – 06.12.2001

Cape Ghir – 09.12.2001

Figure 4 (continued)

### *Coastal currents*

The measurements of vertical profiles of the sea current were performed using the Acoustic Doppler Current Profiler (ADCP) at the locations of the hydrographic stations (Figure 1a and 1b). The results pertaining to the shelf in the depth range between 60-100 m for each hydrographic section are depicted in Figure 5. The results reveal the four distinct current patterns on the shelf.

- 1 Cape Blanc section. A weak poleward current bringing the tropical surface water from the south to the area.
- 2 Dakhla and Cape Bojador sections. Equatorward flow associated with the Canary Current. The strong current at Cape Bojador, reaching 60 cm/s near the surface.
- 3 Cape Juby and Cape Dra. A weak current. Due to the shape of the coastline, the currents are directed towards SWW, which is not fully represented by the equatorward component shown in Figure 5. The westward component of the current (not shown in Figure 5) was however equally low.
- 4 Cape Ghir. The poleward component of the current in the range of  $V=20$  cm/s near the surface.

The current structure shown in Figure 5, complements the information found from the analysis of the hydrographic sections. By combining these data, the two regions with environmental conditions favorable to the retention and enrichment may be identified.

1. Cape Blanc – Dakhla. The frontal region between the tropical Atlantic and the Canary Current domains.
2. Cape Juby to Cape Ghir. A region with quiescent current conditions yet enriched inshore by an ongoing upwelling process.

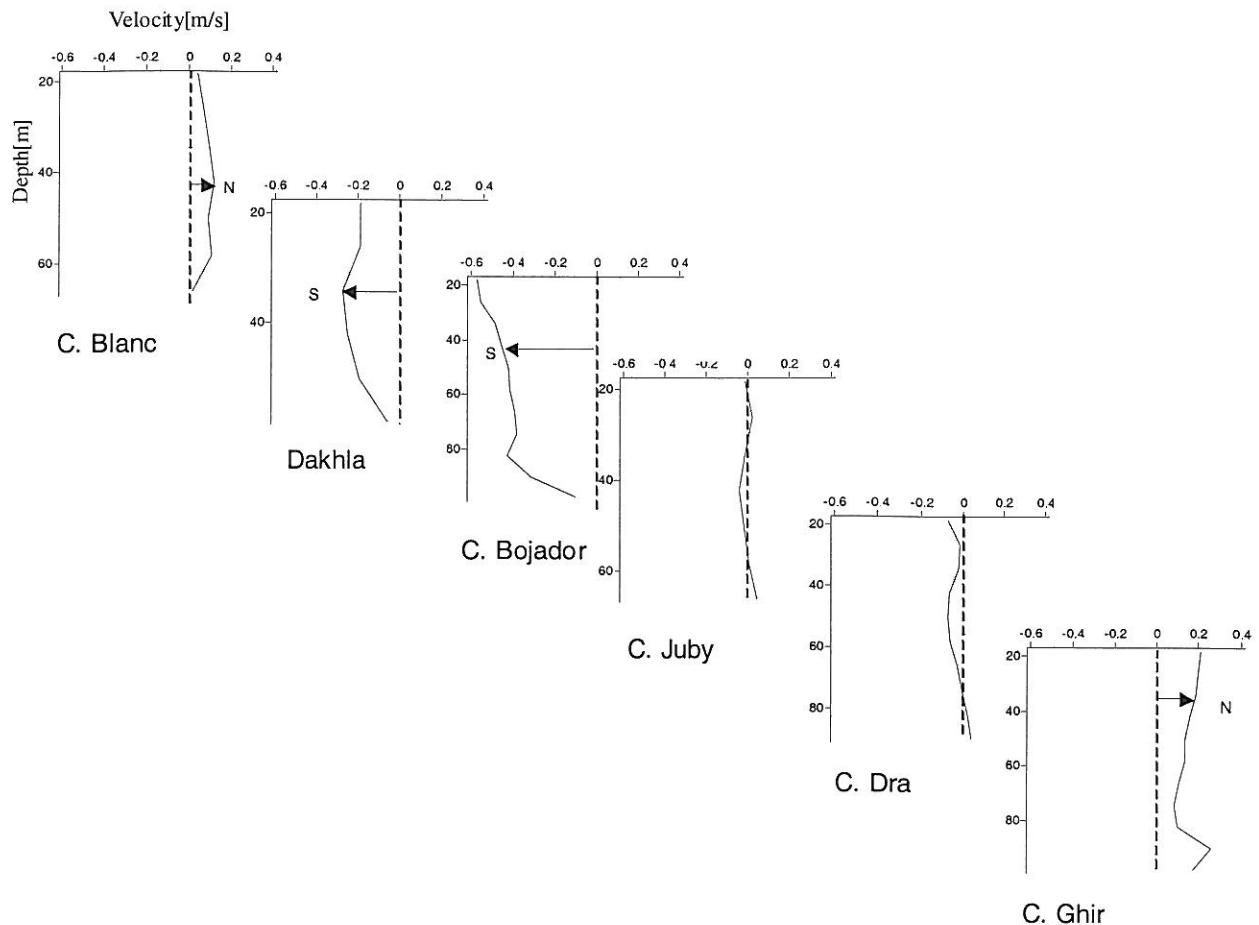

Figure 5 Vertical distribution of the North-South component of the sea current at a depth between 60 and 80m at the locations of hydrographic sections, collected during the survey. Current speed given in m/s.

## 2.2 Distribution of pelagic fish on the shelf from Cape Blanc to Cape Juby.

Figures 6 to 9 show the distribution of the main groups of pelagic fish by contoured acoustic densities.

**Sardine**, *Sardina pilchardus*, was found in dense concentrations between  $21^{\circ}30' \text{ N}$  and  $25^{\circ} \text{ N}$ , Figure 6. The gravity point of the distribution, consisting mainly of adult fish, is more southward as compared to previous surveys at same season, when usually most of the adult fish is located from Dakhla and northwards. Recordings of fish of length less than 20 cm were sparse (Figure 10a) and encountered only in the vicinity of Cape Barbas. This indicates a rather poor recruitment of sardine for this year. The very high concentrations of young sardine reported in the June survey this year is reduced to a small fraction. This fish was then mainly located south of

Cape Barbas and with very rich concentrations also extending south of Cape Blanc. In the area between Cape Bojador and Cape Juby sardine was recorded in high abundance close to the shore. These aggregations consist only of young fish less than 20 cm (Figure 10b).

**Sardinellas** (*Sardinella aurita* and *S. maderensis*) were found in the south, from about 23°N and southwards. It formed three aggregations (Figure 7), but the distribution extends southwards into Mauritania as well. Some young fish (<11-16cm) were found in the shallow waters north of Cape Barbas, but the main part recorded is adult fish, bigger than 30 cm.

**Horse mackerels** (*Trachurus trachurus* and *T. trecae*) were common between Cape Blanc and Cape Barbas, with the same general distribution feature as last year, but at lower abundance. Horse mackerel were also recorded further north to Cape Bojador, but only in patches, (Figure 8).

**Chub mackerel** (*Scomber japonicus*) was recorded at the outer shelf in the southern part, Figure 8. Densest registrations were found southwest of Dakhla.

**Anchovy** (*Engraulis encrasicolus*) were encountered at one event forming a single patch in the vicinity of Cape Blanc (no figure).

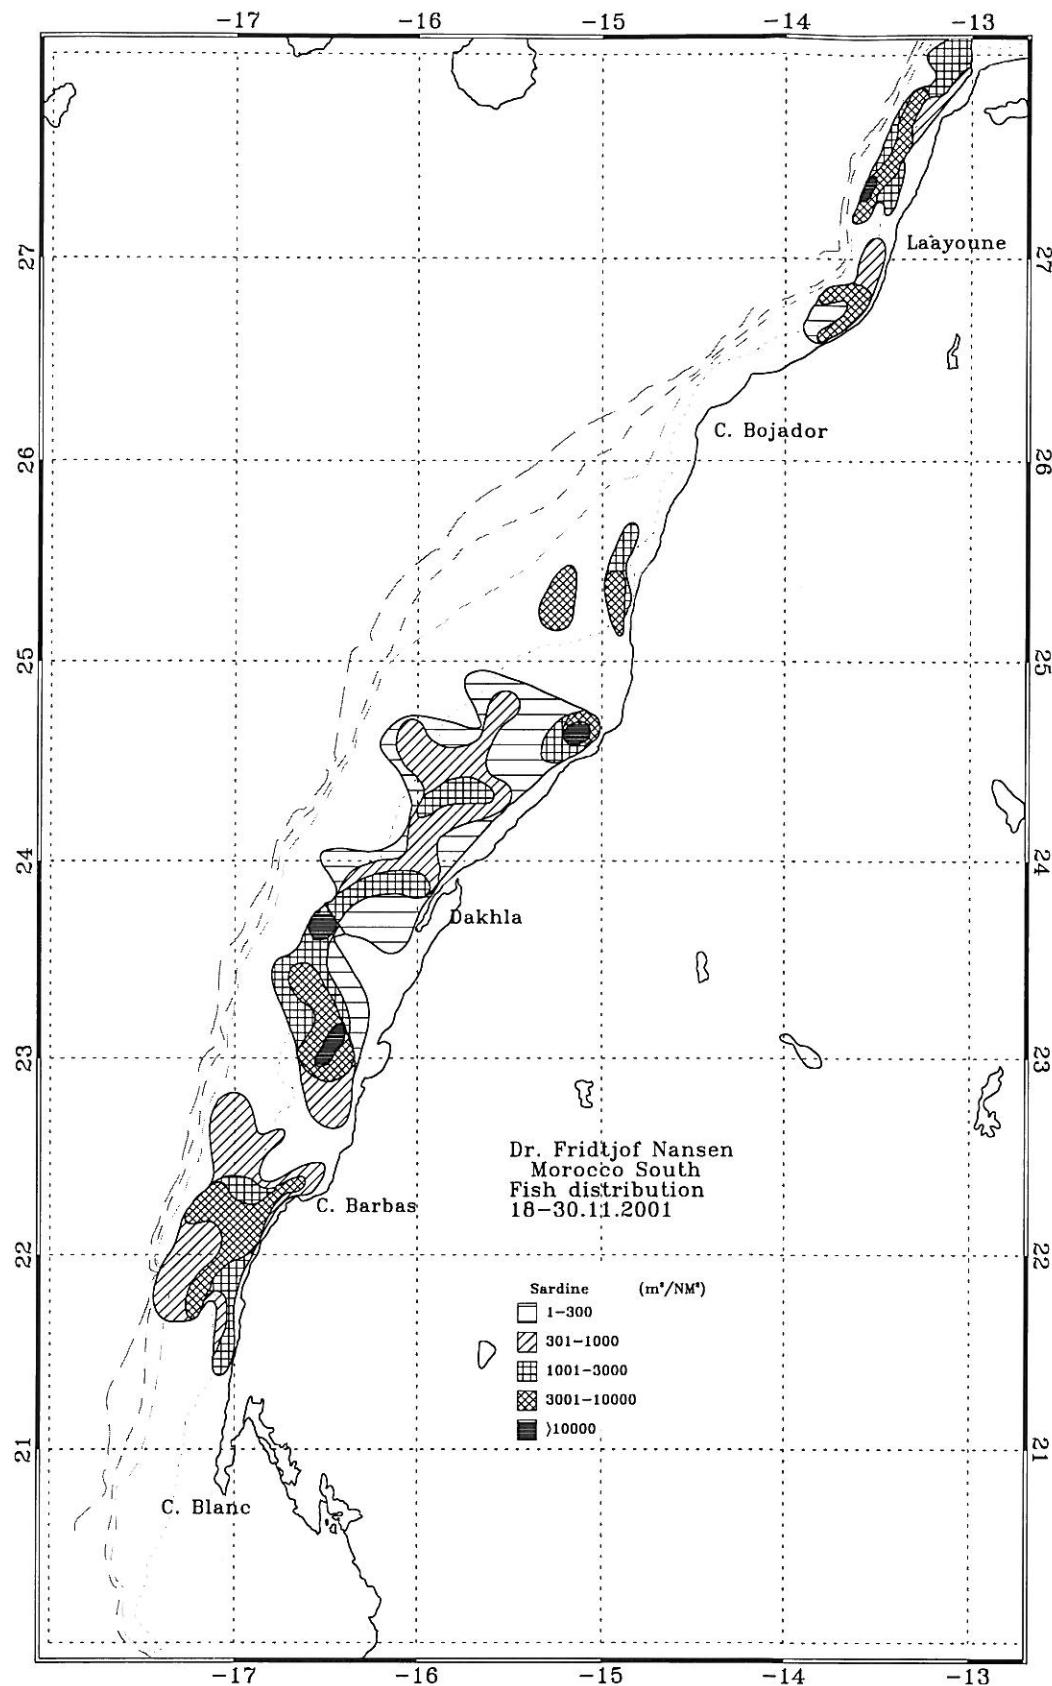

Figure 6 Distribution of sardine, Cape Blanc to Cape Juby. Depth contours as in Fig. 1a.

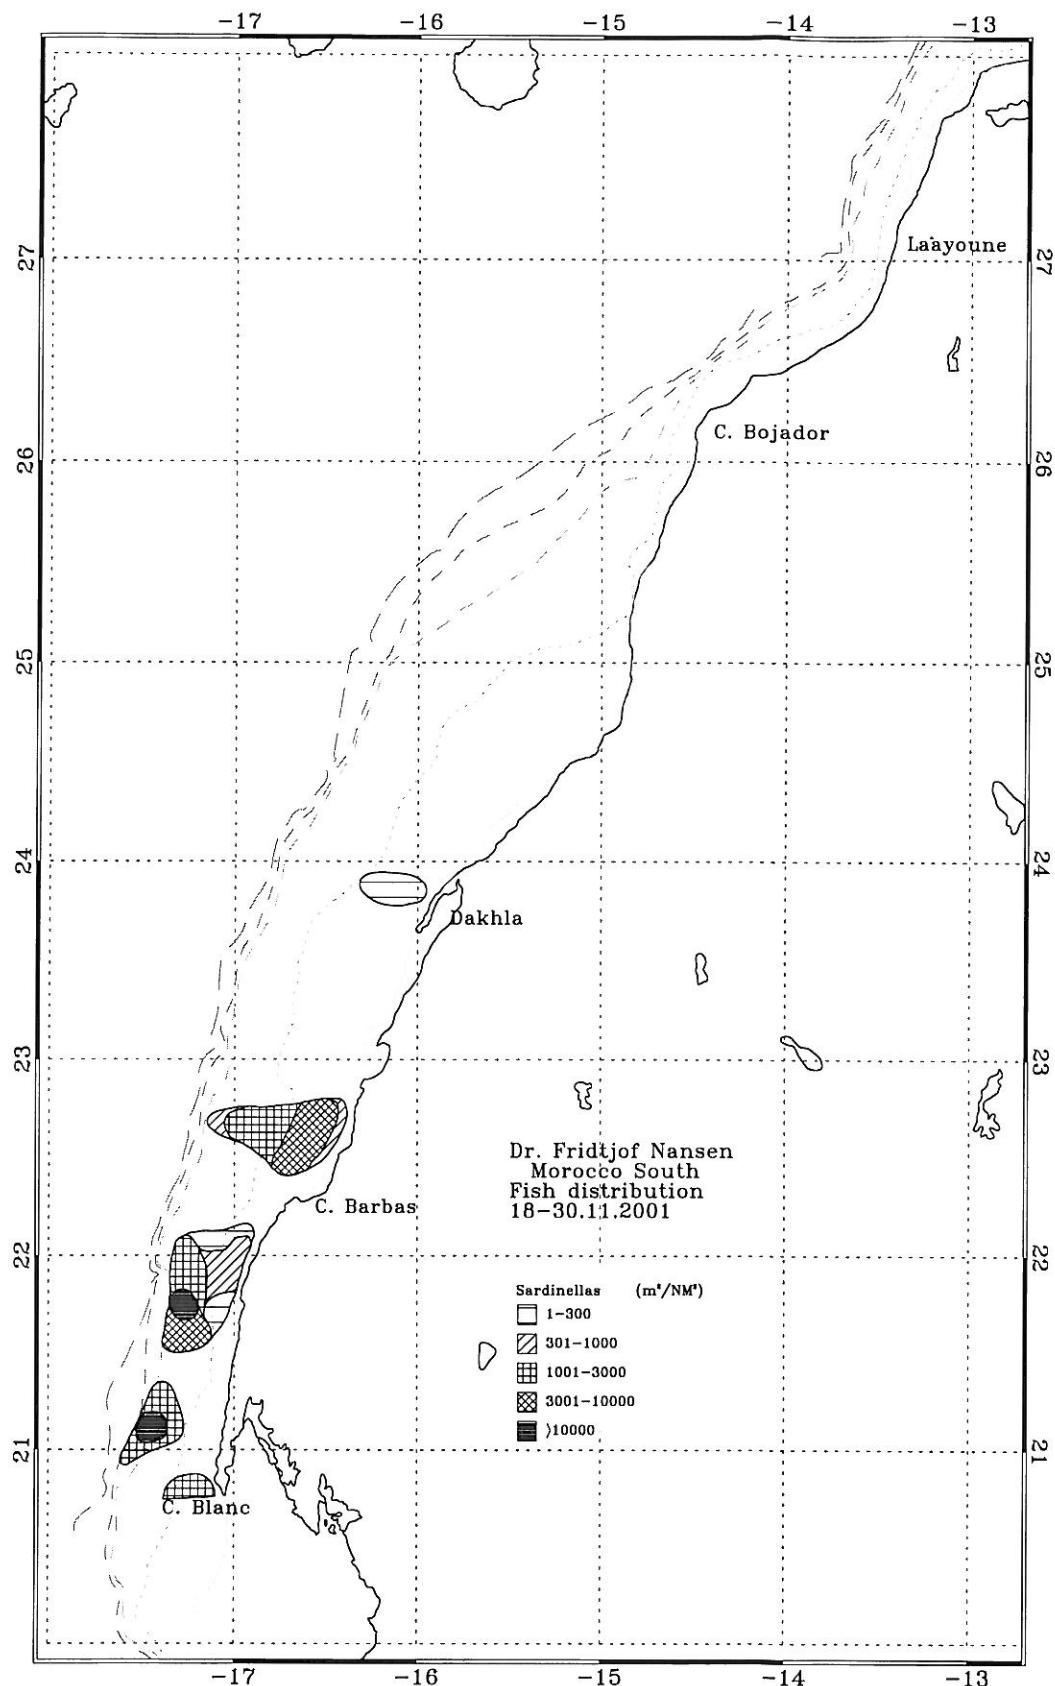

Figure 7 Distribution of sardinella, Cape Blanc to Cape Juby. Depth contours as in Fig. 1a.

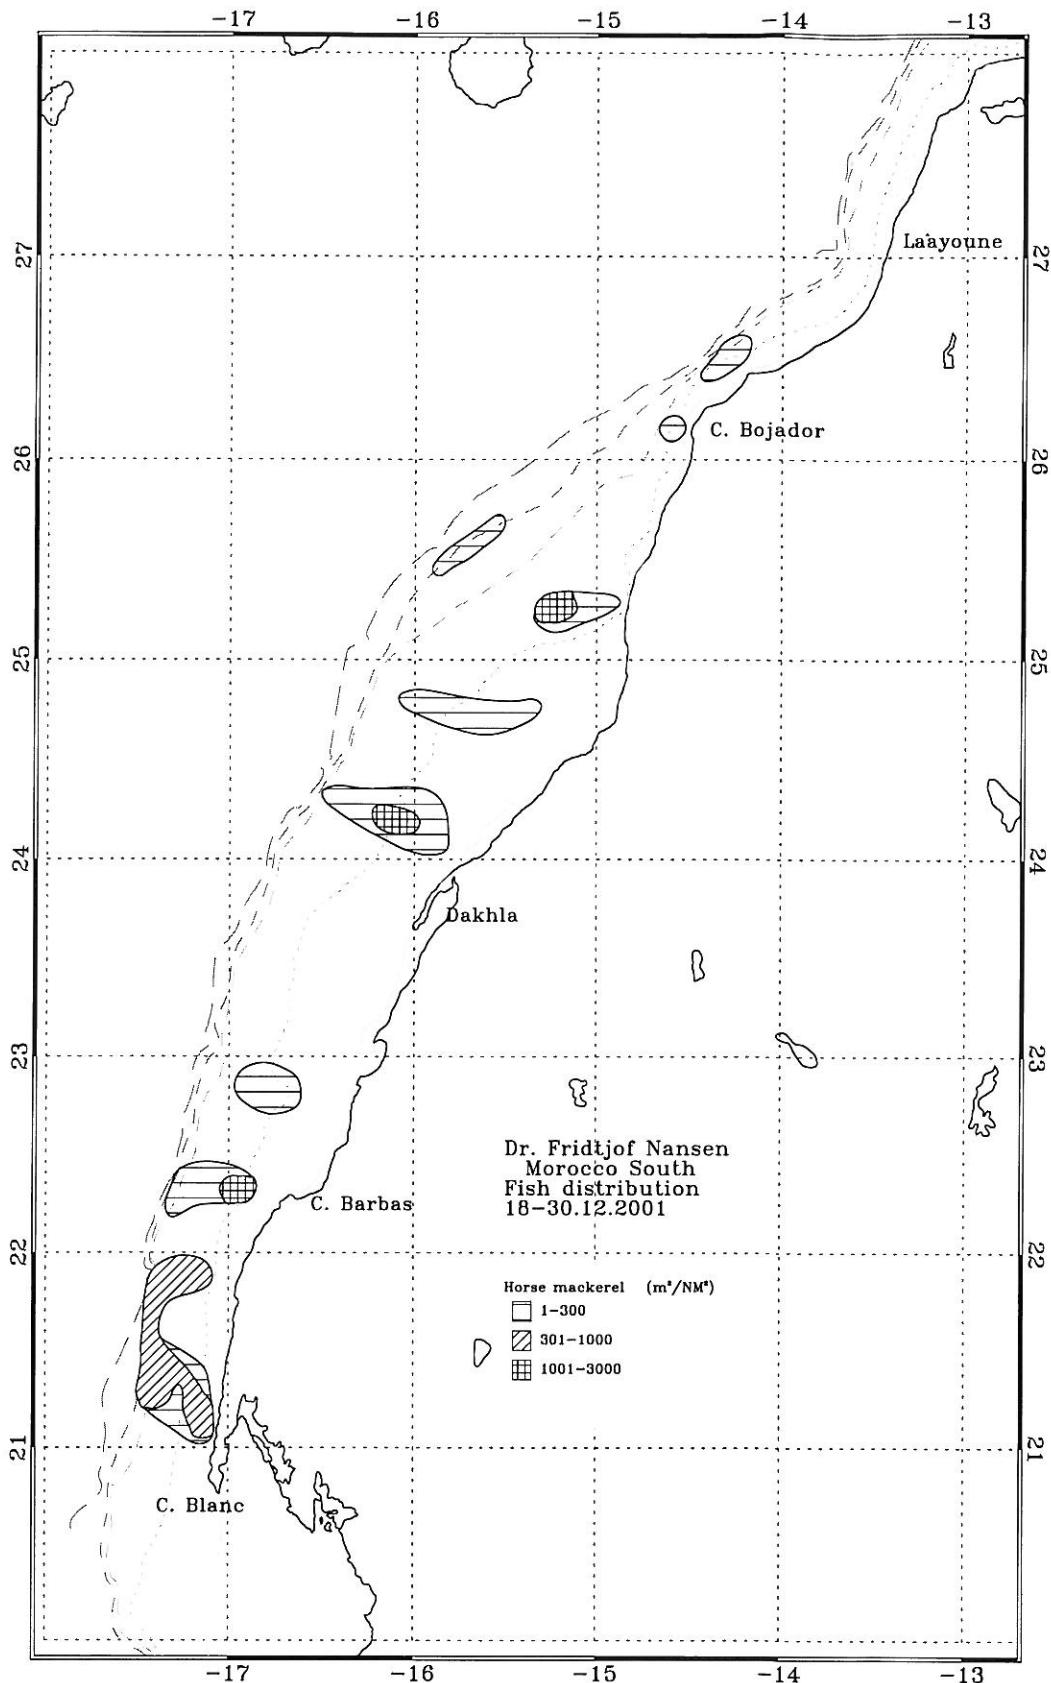

Figure 8 Distribution of horse mackerel, Cape Blanc to Cape Juby. Depth contours as in Fig. 1a.

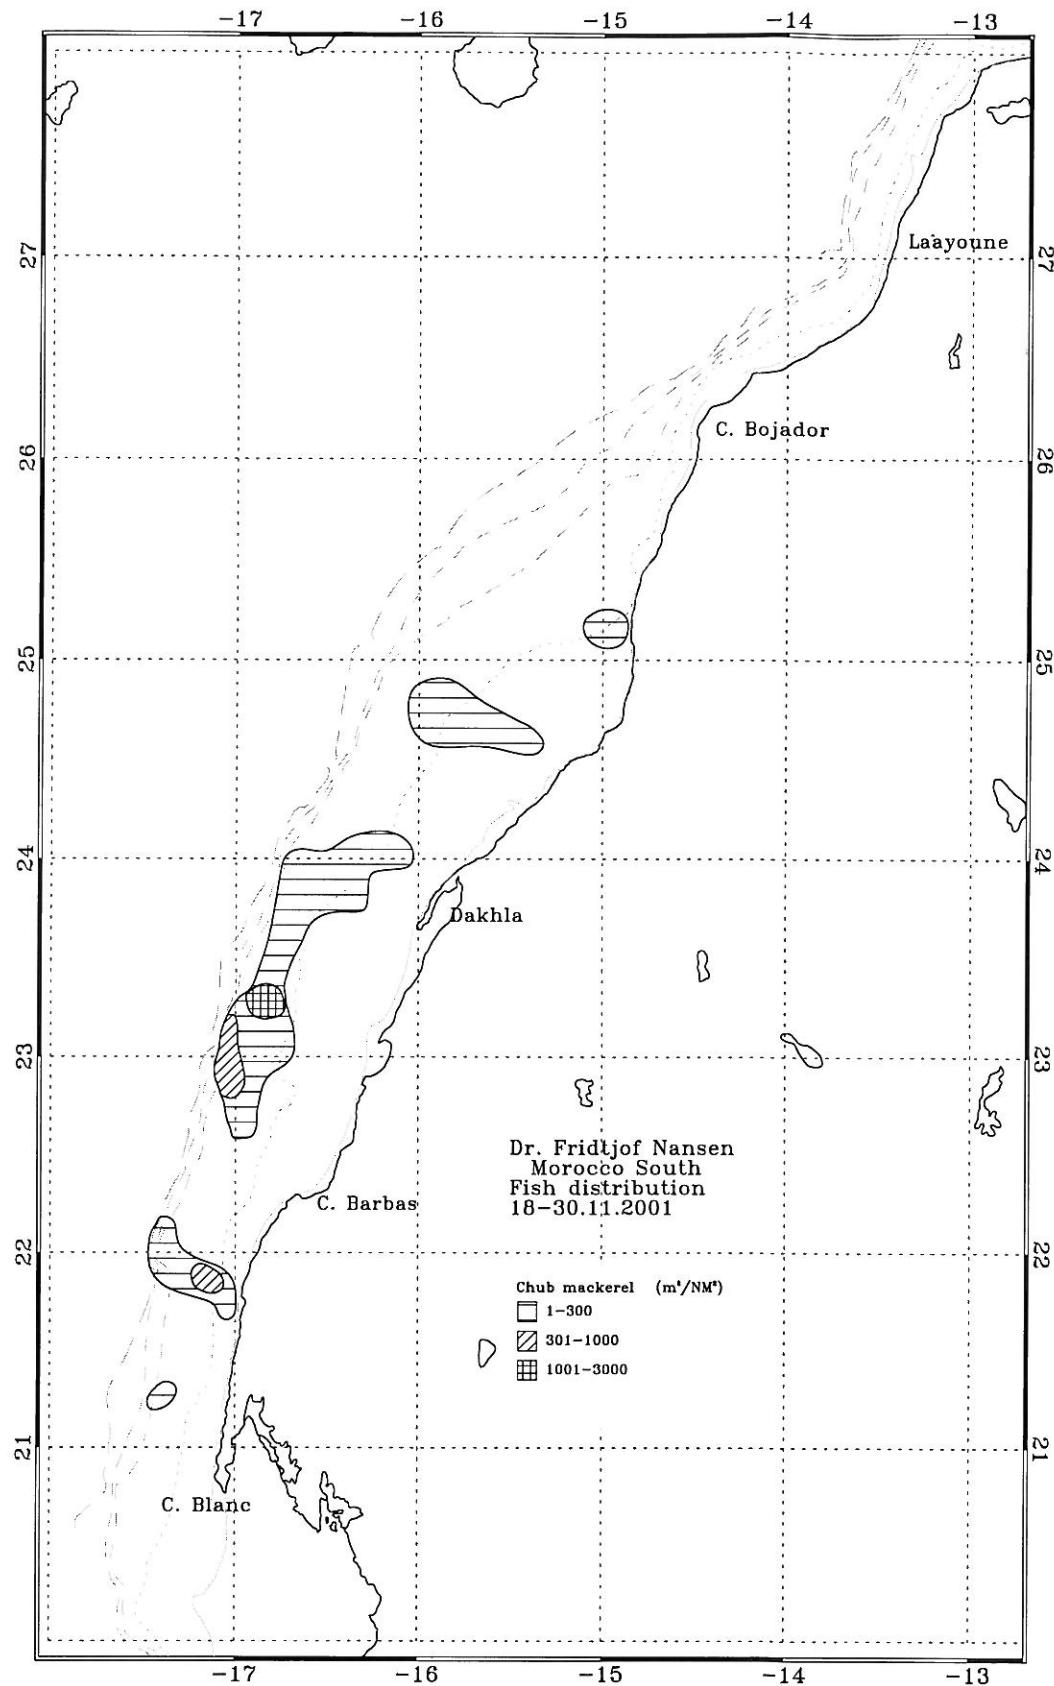

Figure 9 Distribution of chub mackerel, Cape Blanc to Cape Juby. Depth contours as in Fig. 1a.

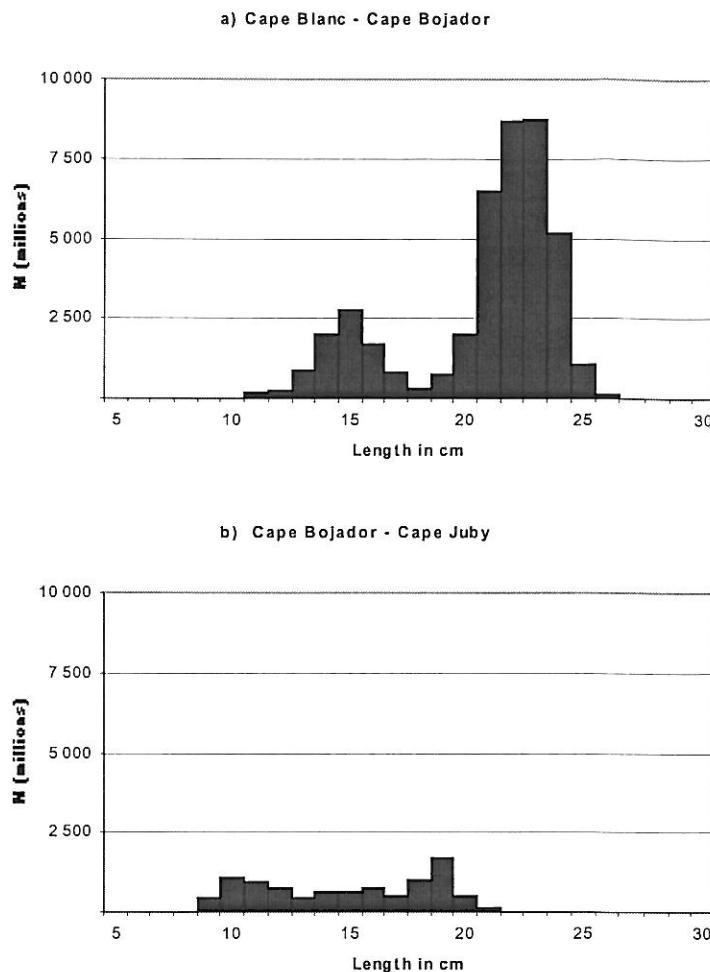

Figure 10 Length frequency distributions sardine Cape Blanc to Cape Juby.

### 2.3 Distribution of pelagic fish on the shelf from Cape Juby to Cape Cantin.

**Sardine** was registered in dense concentrations from Cape Juby to around Sidi Ifni, Figure 11. It was much absent in the Agadir area but again abundant with a bigger patch south of Safi. The aggregations consist mainly of two younger cohorts with modes around 11 and 17cm, Figure 14. The latter cohort was observed in June as well, then at around 10cm modal length.

**Anchovy** was few and far between during this survey (Figure 12), in contrast to earlier years, but in line with the finding in June this year. The anchovy generally seems to be in a period of low abundance.

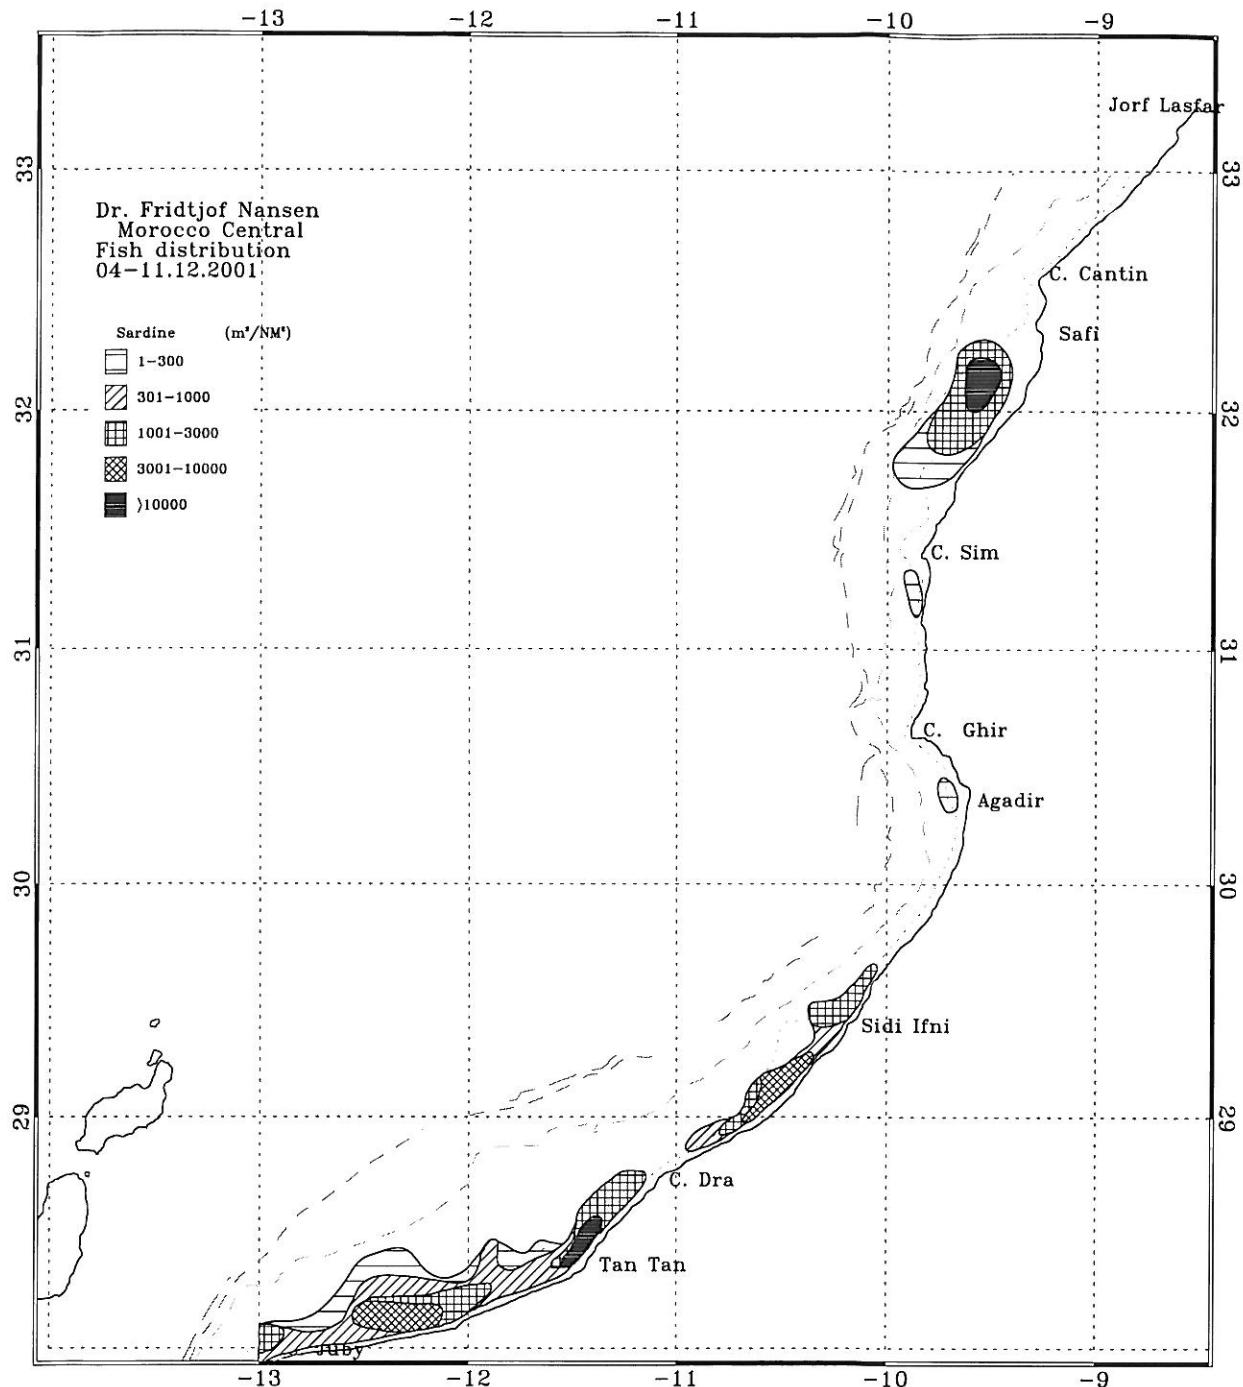

Figure 11 Distribution of sardine, Cape Juby to Cape Cantin. Depth contours as in Fig. 1a.

Recordings of **horse mackerel** were very few while **chub mackerel** was more common but with higher densities only in the area south of Safi, Figure 13.

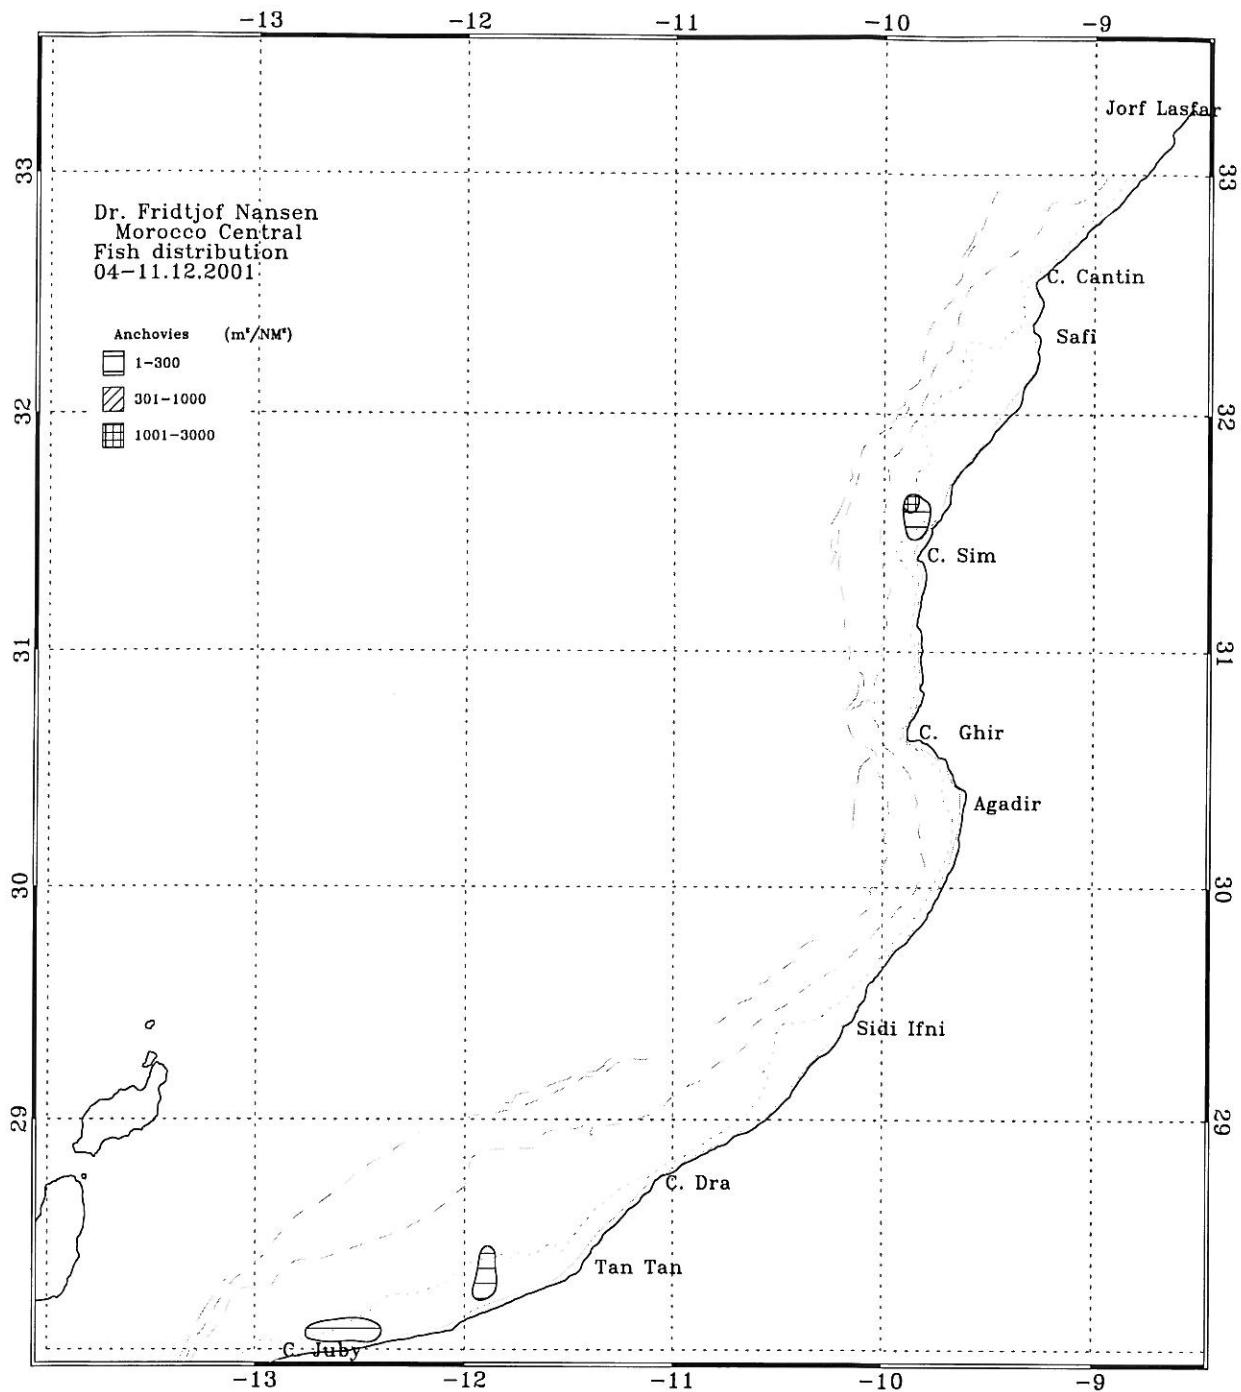

Figure 12 Distribution of anchovy, Cape Juby to Cape Cantin. Depth contours as in Fig. 1a.

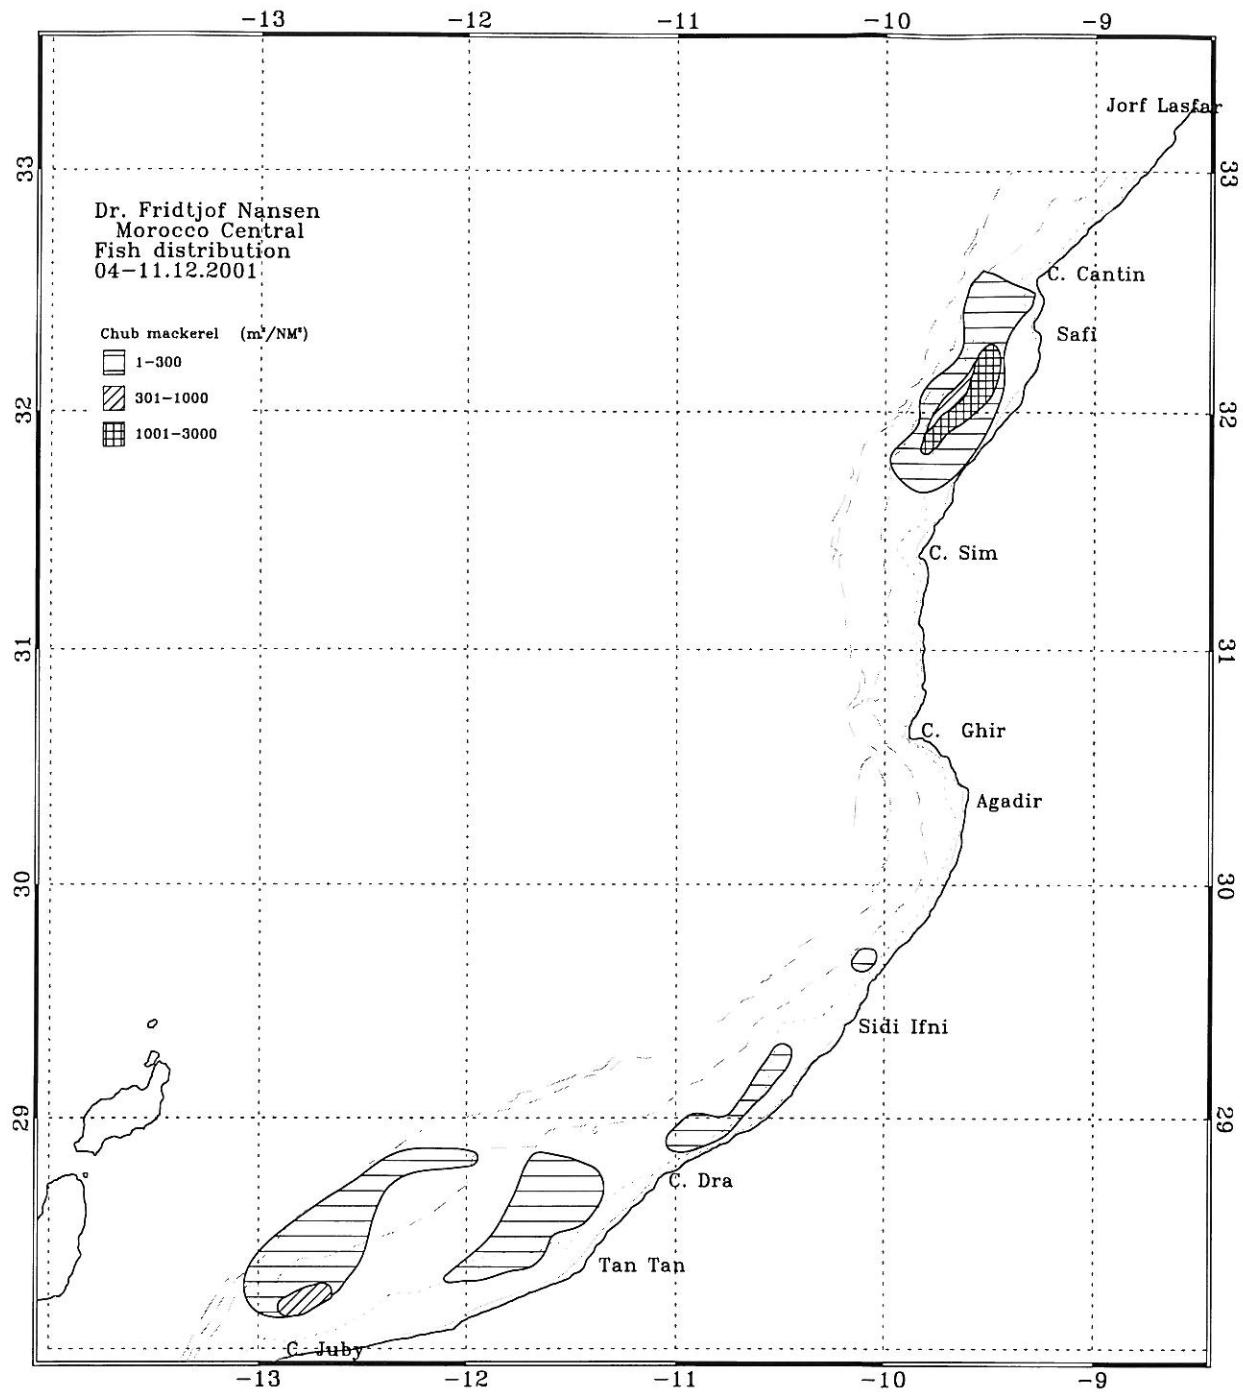

Figure 13 Distribution of chub mackerel, Cape Juby to Cape Cantin. Depth contours as in Fig. 1a.

## 2.4 Biomass estimates

A summary on biomass estimates is given in Table 1 below. More detailed biomass estimates in number and weight by length groups are shown in Annex I.

### *Cape Blanc-Cape Bojador*

The **sardine** was estimated to 3.5 million tonnes, slightly 20% more than the 2.9 million estimated in June. However, if the sardine in Mauritania in June is included, the biomass is since June reduced 8% from 3.8 million tonnes. The length distribution is earlier shown in Figure 10. Most of the fish in terms of biomass now consist of older fish. Compared with earlier years, the development in the “adult” part of the stock (i.e. fish >19 cm) is:

1996:	4 600 000 tonnes	47 400 mill fish
1997:	240 000 tonnes	2 900 mill fish
1998:	340 000 tonnes	3 400 mill fish
1999:	1 000 000 tonnes	13 700 mill fish
2000:	1 260 000 tonnes	13 200 mill fish
June 2001*:	1 975 000 tonnes	22 500 mill fish
2001:	3 200 000 tonnes	32 000 mill fish

\* including sardine in Mauritania

The strong increase during the last half year is in part due to intrinsic growth in the adult population, but mainly due to recruitment of a very strong year class into the adult stage, as can be seen from the about 70% increase in number abundance in the above table. The young fish (<20 cm) constitute only about 10 billion fish. As a rough recruitment index this is a rather low number.

**Sardinella** was estimated to roughly 2.5 million tonnes of which 1.5 and 1.0 million are round and flat sardinella respectively. The fish is located between Cape Blanc and 24°N and seems to constitute most of the regional stock of sardinellas. In the preceding survey in Senegal and Mauritania only 650 000 tonnes of sardinella were estimated in total, see Annex I.

The two species of **horse mackerel** combined was estimated to 340 000 tonnes, of which about roughly 100 000 and 240 000 were Atlantic and Cunene horse mackerel respectively. The Cunene horse mackerel forms a major part of the stock, distributed mainly south of Cape Barbas.

#### *Cape Bojador-Cape Juby*

Estimated **sardine** in this region is since June reduced from 600 000 to 330 000 tonnes. Compared with the November survey the last year the biomass is also down from about 600 000 tonnes. The reduction has been especially hard in the adult biomass and what remains in this area seems to be mainly young fish, less than 20 cm.

#### **Cape Juby – Cape Cantin**

The **sardine** is estimated to 890 000 tonnes, a slight increase from 770 000 tonnes of December 2000. The abundance in numbers is stable, 29 and 28 billion in 2000 and 2001 respectively. The fish in the size range 15-20 cm has been reduced since last year but generally younger recruits seems to be of the same level as earlier. (Annex I). The area between Cape Dra and Agadir was surveyed twice as some surface schooling occurred during the first coverage. The biomass estimates from the two coverages were 147 000 and 155 000 tonnes respectively.

**Anchovies** was estimated to only 5 000 tonnes, a drastic reduction from the 100 000 tonnes estimate in 2000, but in line with the 7 000 tonnes estimated earlier in May this year. Anchovies are known from many parts of the world to undergo large-scale natural fluctuations, and the stock in this region seems at present to be in its low phase.

Table 1 Morocco. Summary of biomass estimates of pelagic fish, 1000 tonnes.

## CHAPTER 3 CONCLUDING REMARKS

---

The survey was conducted successfully in the period 17<sup>th</sup> November to 18<sup>th</sup> December with an acoustic course track of 4700 NM and 52 fishing stations. The limits of the school areas of the sardine, anchovy and horse mackerel are thought to have been well determined and the main areas adequately sampled. The weather conditions did not put any constraints on the survey work.

The oceanographic observations conducted during the survey, indicate a warmer conditions than those observed during previous winter surveys, particularly in the southern part of the survey area. The sea surface temperature inshore between Cape Blanc and Cape Bojador was 2°C higher than in November/December 2000. An influx of tropical surface water from the tropical Atlantic was observed to the north of Cape Blanc. This phenomenon might have caused the northward shift of northern boundary of the tropical ecosystem, which in turn may account for the observed presence of the sardinella stocks north of Cape Blanc.

Figure 15 gives a general overview on the major aggregations of pelagic fish with rounded biomass figures. The biomass estimates are also summarised in Table 1.

Generally the sardine in the southern region has a more southern distribution pattern as normal for the season; the main part of the stock is found south of Dakhla and juveniles are generally lacking in the region. The biomass of sardine between Cape Blanc and Cape Bojador has increased from 2.0 million tonnes in November/December 2000 to 3.5 million during the last survey. Only 320 000 tonnes of the present stock is juvenile fish. It is not expected major growth in the adult stock during 2002, as the stock, because of its size structure, already has realized its growth potential. Further growth will have to come from future strong recruitment. Sardine in the region Cape Bojador-Cape Juby is estimated to 330 000 tonnes, nearly half of the size of December 2000. This area holds considerable amount of young fish that will grow during 2002 if not decimated too hard by fishing. Further north, the stock between Cape Juby and Cape Cantin is estimated to 890 000 tonnes, an increase from 770 000 tonnes in November 2000 or 730 000 in June this year. The recent growth is attributed to 240 000 tonnes recorded off Safi while the sub-stock Cape Juby-Agadir has declined. Recruitment seems now to be stronger than reported from the June survey and is slightly below normal.

Most part of the northwest African stock of sardinellas was recorded between Cape Blanc and 23°N during the survey. They formed dense schools, and seemed to be objects of a strong fishing pressure in the southern part. The biomass was estimated to 2.5 million tonnes while the

remaining part of the stock in Senegal and Mauritania was estimated from the preceding surveys in these waters to 650 000 tonnes.

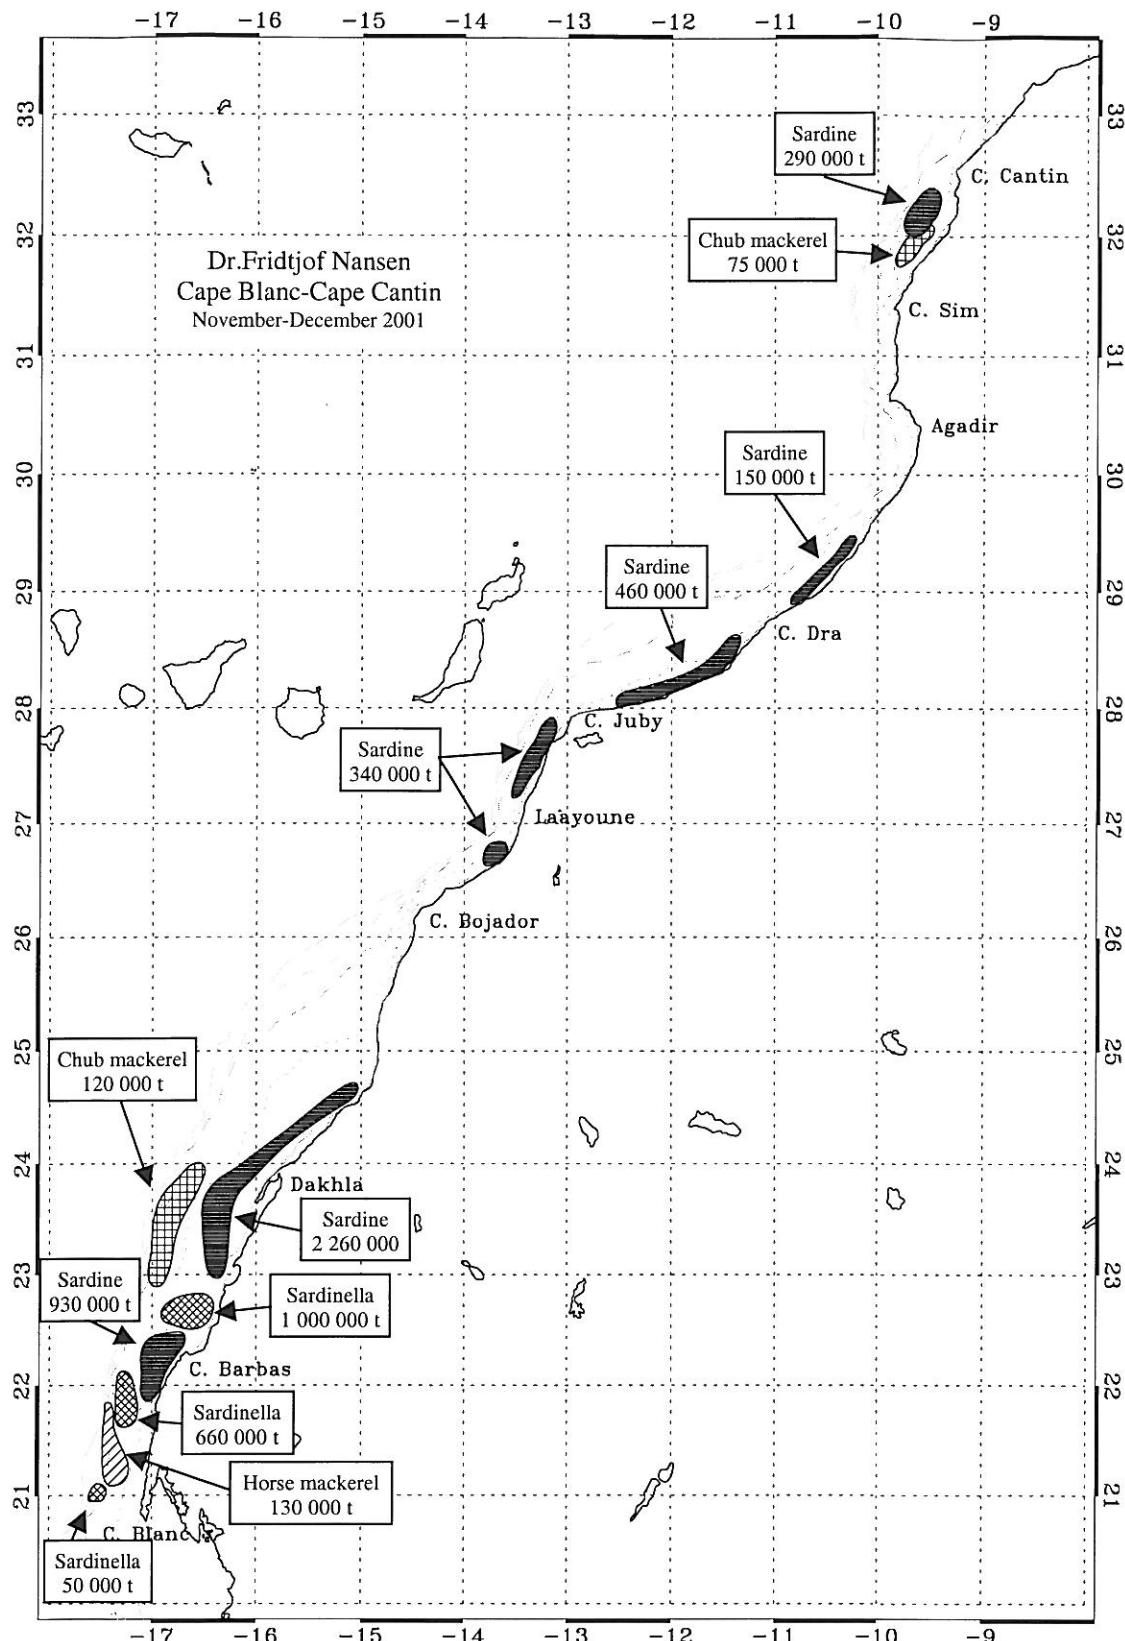

Figure 15. Map of the major pelagic fish concentrations with estimated abundance (tonnes), Cape Blanc to Cape Cantin.

Horse mackerel was forming aggregations between Cape Blanc and Cape Barbas and was else found in scattered patches in the whole survey area. The combined estimate of the two species of horse mackerel is 365 000 tonnes of which 240 000 tonnes is Cunene horse mackerel south of Cape Barbas.

Anchovy registrations were poor, less than 8 000 tonnes, and the stock seems to be in a very low state at the moment. The stock has been in steady decline since its high level of 400 000 tonnes in 1998. Anchovies and sardines compete to a large extent in the same niche in the ecosystem and the low level of anchovies could be associated with the high level of the sardine in the later years.

### **Trends 1995-2001, sardine**

Figure 16 shows the biomass estimates of sardine compared with results from previous “Dr. Fridtjof Nansen” surveys. Figure 17 shows the biomass figures 1995-2001 by length classes. Both figures display that the stock between Cape Blanc and Cape Juby, has shown a remarkably steady recover from its drastic decline observed at the end of 1997. However, if 900 000 tonnes of sardine recorded in Mauritania in June is included, the stock development seems to have culminated during the last half year. The high number of juveniles in the central stock, recorded in June 2001 (Figure 17), has been heavily reduced during the last 5 months and the recruiting part of the stock is now at a rather low level. For this reason there is not expected further intrinsic growth in the southern sardine population in the forthcoming year. The reason for the heavy decimation of juveniles since June is unknown, but it is possible that intensive fishing activities in the area around Cape Blanc have had its effect on the juveniles. Cross checks with capture statistics could clarify this issue better.

Small fish, as observed in the later years, dominates the central stock between Cape Juby and Safi. The level of the stock is about the same as observed in November 2000 and in June 2001. The abundance in the area Cape Juby – Cape Dra has been reduced since the two previous surveys. This is however compensated by an increase in the abundance in the waters off Safi. Due to the relative high fishing pressure, the central stock will continue to be dependent of steady good recruitment, as there is no buffer from presence of older year-classes.

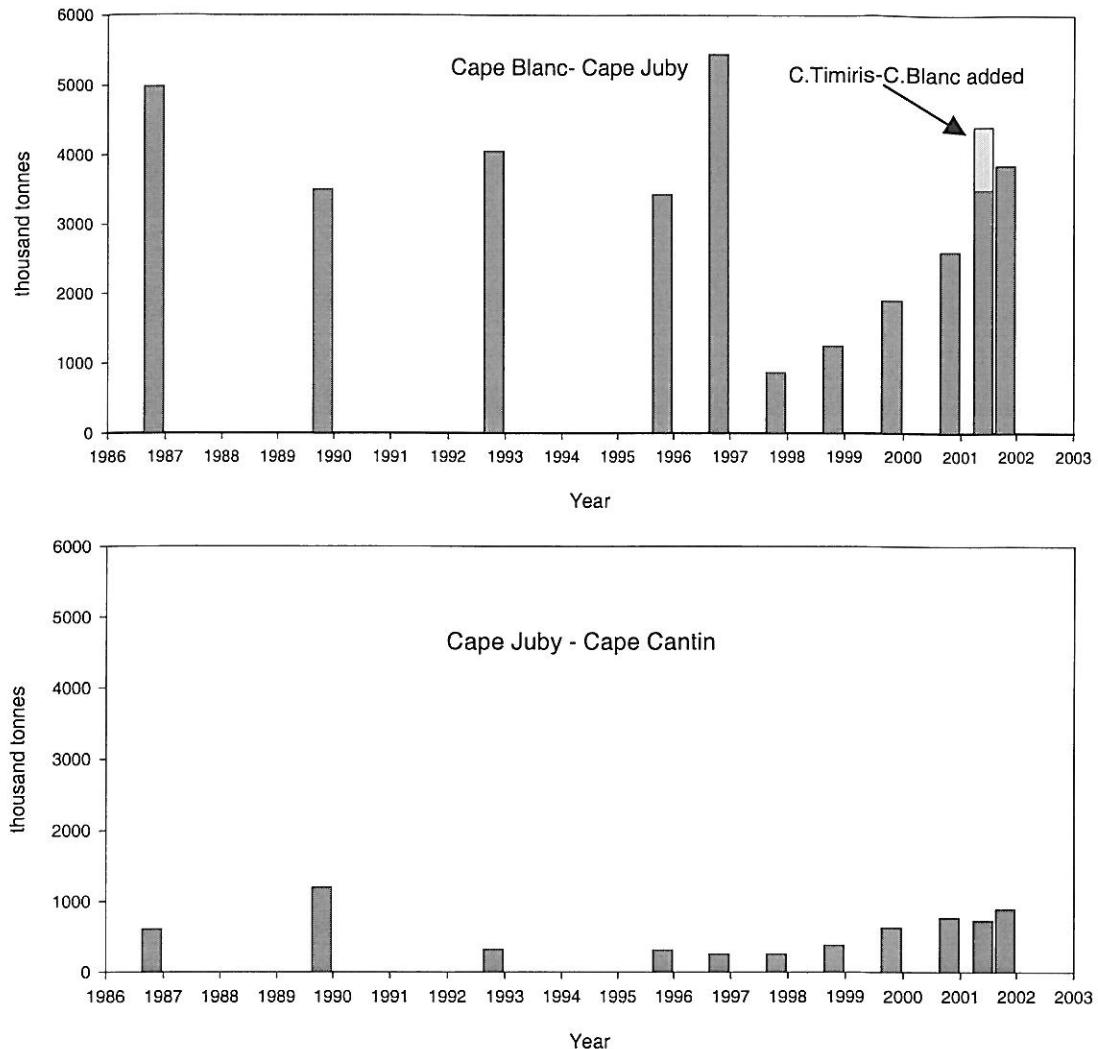

Figure 16 Sardine biomass estimates Cape Blanc-Cape Juby and Cape Juby- Cape Cantin,  
Dr. Fridtjof Nansen 1986-2001.

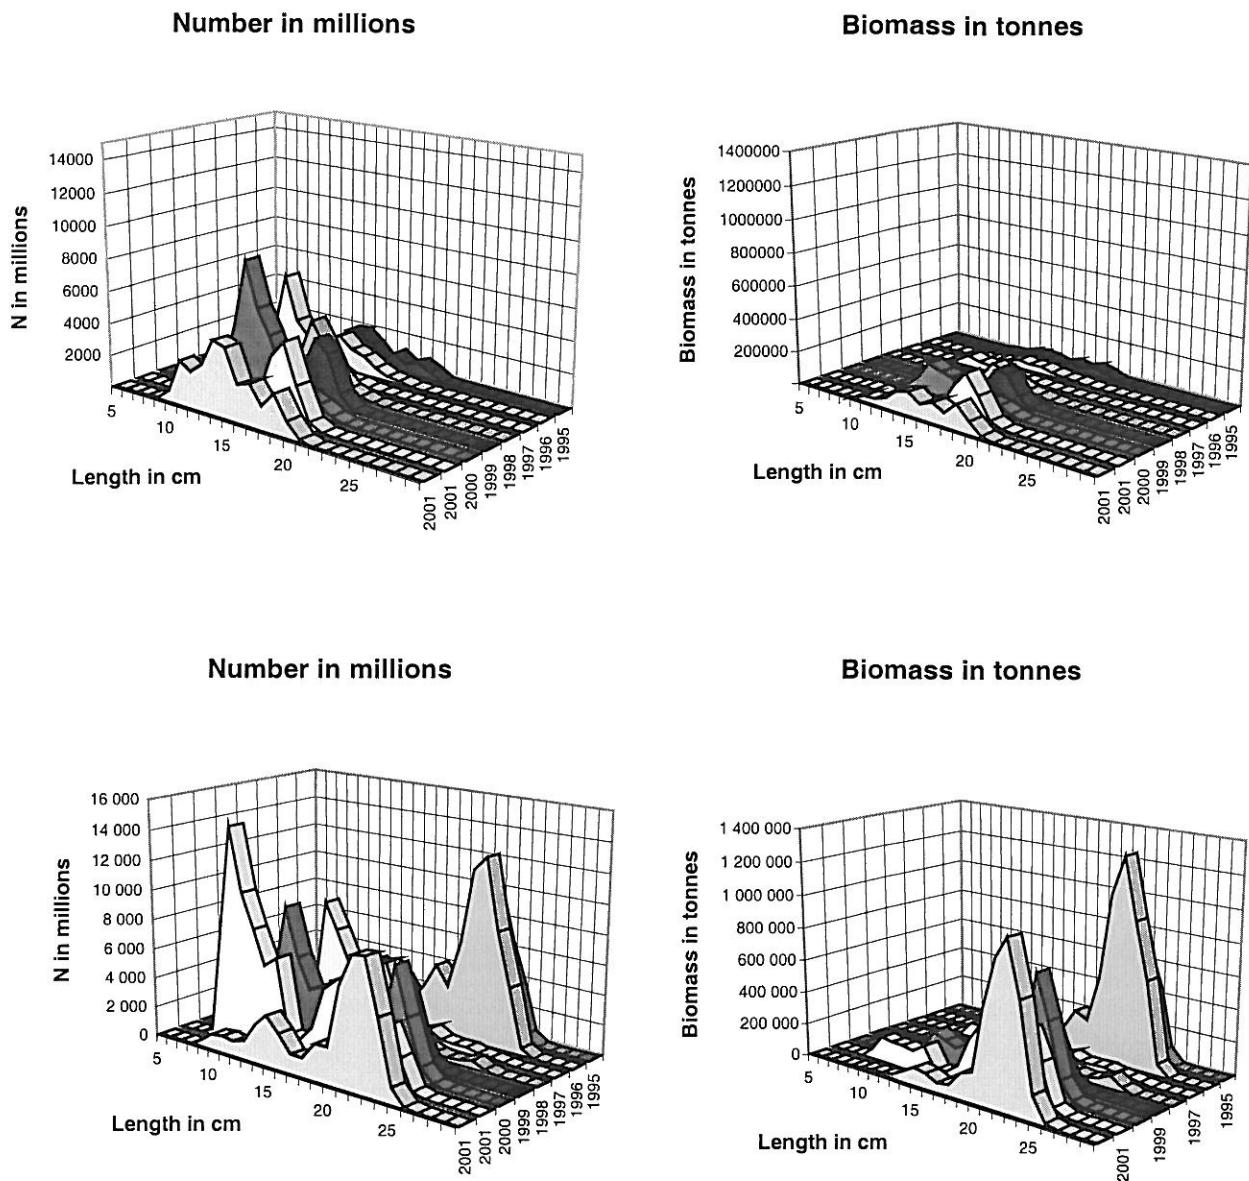

Figure 17. Numbers and biomass by length class, 1995-2001. Cape Juby - Cape Cantin (top) and Cape Blanc – Cape Juby (bottom).

## RESUMÉ

La campagne a été conduite avec succès durant la période du 17 Novembre au 18 Décembre 2001, suivant un schéma de prospection acoustique de 4700 miles nautiques et 52 stations de pêche de contrôle. Les bancs de sardine, anchois, chincharts, ont été bien déterminés et délimités et leurs principales zones adéquatement échantillonnées. Les travaux pendant cette campagne n'ont pas subi de contraintes majeures par les conditions météorologiques.

Les observations météorologiques conduites durant cette prospection indiquent un réchauffement des eaux par rapport aux conditions observées durant les précédentes campagnes, particulièrement dans la partie sud de la prospection. La température superficielle des eaux côtières a été de 2 degrés centigrades supérieure à celles de Novembre/Décembre 2000. Un flux superficiel des eaux tropicales atlantiques a été observé vers le nord du Cap Blanc, ce phénomène pourrait causer le déplacement (northward shift) vers le nord, de la limite nord de l'écosystème pélagique, qui pourrait par conséquent, expliquer la présence des stocks de sardinelles au nord du Cap Blanc .

Une vision générale des majeures concentrations des poissons pélagiques, avec des valeurs de biomasses arrondies, est présentée dans la figure 15. Les estimations de biomasse sont également résumées dans la tableau 1.

Dans la zone sud, la distribution de la sardine est plus méridionale que dans le schéma normal de distribution pendant cette saison; la partie le plus importante se trouve au sud de Dakhla, avec une absence de juvéniles dans cette région. La biomasse de sardine entre Cap Blanc et Cap Bojador a augmenté de 2.0 million de tonnes en Novembre/Décembre 2000 à 3.5 million durant cette dernière campagne, dont seulement 320 mille tonnes sont des juvéniles.

Il n'est pas prévu de croissance majeure du stock durant 2002, étant donné que les structures de taille ont déjà réalisé le potentiel de croissance. D'avantage de croissance devrait provenir d'un fort recrutement future. La biomasse de sardine est estimée à 330 mille tonnes dans la région Cap Bojador-Cap Juby, près de la moitié de sa taille en Décembre 2000, cette région comporte une quantité considérable de jeunes poissons qui grandiront durant 2002 s'ils ne sont pas durement décimés par la pêche.

Plus au nord, le stock entre Cap Juby et Cap Catin est estimé à 890 mille tonnes, en augmentation des 770 mille tonnes en Novembre/Décembre 2000 et 730 mille tonnes en Juin dernier. Cette récente croissance est attribuée aux 240 mille tonnes détectées au niveau de Safi, alors que la partie du stock entre Agadir et Cap Juby a diminué. Le recrutement semble actuellement plus fort que durant la campagne de Juin mais reste légèrement en dessous de la normale.

La plupart des stocks nord-ouest africains de sardinelles ont été détectés, pendant cette campagne, entre Cap Blanc et 24° N. Ils sont formés de bancs très denses et semblent être l'objet d'une forte

pression de pêche dans leur partie sud . Leurs biomasses est estimée à 2.5 million de tonnes, alors que la partie restante du stock dans les eaux du Sénégal et en Mauritanie a été estimée lors des précédentes campagnes à 650 mille tonnes.

Les chinchards étaient regroupés en bancs entre Cape Blanc et Cap Barbas, ils étaient dispersés en petits agrégats sur toute la zone prospectée. L'estimation combinée de la biomasse des deux espèces était de 365 mille tonnes dont 240 mille tonnes de chinchard noir au sud du Cap Barbas.

Les faibles détections d'anchois ont enregistré une biomasse de moins de 8 000 tonnes. Le stock semble être dans un très faible état en ce moment, il est en déclin progressif depuis son plus haut niveau atteint en 1998. L'anchois et la sardine sont dans une grande mesure compétiteurs de la même niche de l'écosystème pélagique et le faible niveau du stock d'anchois pourrait être associé avec la récupération du stock de la sardine depuis 1998.

### **Tendances du stock sardinier pendant la période 1995-2001**

La figure 16 montre les estimations de la biomasse de la sardine, comparées avec les précédentes évaluations effectuées lors des campagnes à bord du 'Dr. Fridtjof Nansen', les évaluations de la biomasse par classe de taille sont présentées sur la figure 17. Les deux figures montrent que le stock entre Cap Blanc et Cap Juby présente une remarquable reconstitution progressive depuis sa chute observée à la fin de 1997. Par ailleurs, si les 900 milles tonnes rencontrées dans les eaux mauritaniennes en Juin sont incluses, le niveau de ce stock semble avoir culminé durant ce dernier semestre.

Le grand nombre de juvéniles du stock enregistré en Juin 2001 (Figure 17) a été lourdement réduit durant ces cinq derniers mois et la partie des nouvelles recrues est plutôt à un bas niveau; Pour cette raison, une croissance intrinsèque de la population du stock sud durant l'année prochaine pas prévisible.

La raison de cette forte décimation des juvéniles depuis Juin dernier reste toujours inconnue, mais, il est possible que l'activité de pêche intensive que connaît la région autour du Cap Blanc a eu son effet sur les juvéniles. Une analyse croisée avec les statistiques de capture, pourrait mieux élucider cette question.

Les poissons de petites taille observés durant ces dernières années dominent le stock entre Cap Juby et Safi. Le niveau du stock est presque au même niveau qu'en Novembre 2000 et Juin 2001. L'abondance dans la zone Cap Juby-Cap Dra a été réduite depuis les deux campagnes précédentes, elle est toutefois compensée par un accroissement d'abondance dans les eaux de la région de Safi. Le stock central continuera d'être dépendant d'un bon recrutement stable, d'autant qu'il n'y a pas de capacité d'effet tampon à partir des classes d'âges supérieures.

### **Annex III Instruments and fishing gear used**

The Simrad EK-500, 38kHz echo scientific sounder was used during the survey for fish abundance estimation. The Bergen Echo Integrator system (BEI) logging the echogram raw data from the sounder, was used to scrutinize the acoustic records, and to allocate integrator data to fish species. All raw data was stored to tape, and a backup of the database of scrutinized data, stored. The details of the settings of the 38kHz where as follows:

<b>Transceiver-1 menu</b>	Transducer depth	5.5 - 7.5 m
	Absorbtion coeff.	10 dB/km
	Pulse length	medium (1ms)
	Bandwidth	wide
	Max power	2000 Watt
	2-way beam angle	-21.0 dB
	SV transducer gain	27.45 dB
	TS transducer gain	27.65 dB
	Angle sensitivity	21.9
	3 dB beamwidth	6.8°
	Alongship offset	-0.03°
	Athwardship offset	0.06°
<b>Display menu</b>	Echogram	1
	Bottom range	10 m
	Bottom range start	10 m
	TVG	20 log R
	Sv colour min	-67 dB
	TS Colour minimum	-60 dB
<b>Printer- menu</b>	Range	0 - 50 or 0 -100 m and 100 - 350m
	TVG	20 log R
	Sv colour min	-63 dB
<b>Bottom detection menu</b>	Minimum level	-40 dB

A calibration experiment using a standard copper sphere, performed off Langstrand, Walvis Bay 19 April 2001 gave the following results:

Sv Transducer gain 27.37 dB  
Ts Transducer gain 27.49 dB

### **Fishing gear**

The vessel has two different sized "Åkrahamn" pelagic trawls and one "Gisund super" bottom trawl. For all trawls, the Tyborøn, 7.8m<sup>2</sup> (1670 kg) trawl doors were used. Complete drawings of the trawls used are included.
