## CHAPTER 1 INTRODUCTION

---

### 1.1 Objective of the cruise

The general objectives of the survey were to estimate biomass and map the distribution of small pelagic fish stocks off NW Africa (Morocco, Mauritania, Senegal and the Gambia) by hydro-acoustic methods and describe the hydrographic conditions in the region over a period of 50 days, in November-December 2005. For Senegal and The Gambia the agreed objectives were as follows:

- To map the distribution and estimate the biomass for the main small pelagic fish using hydro-acoustic methods. The species of interest were: sardinellas (*Sardinella aurita*) and (*Sardinella maderensis*), horse mackerel (*T. trecae*), false scad (*Decapterus rhonchus*), and anchovy (*Engraulis encrasicolus*).
- To identify and describe the size distribution of the target fish populations by midwater and bottom trawl sampling and process the catches by recording weight and number by species.
- Collect biological data and otoliths of the main target species, especially *Sardinella aurita*, *S. maderensis* and *T. trecae*.
- To sample standard hydrographical transects for temperature, salinity and oxygen at every degree latitude, at about 12°40'N, 13°40'N, 14°50'N and 15°50'N and additionally at the 50 m and 200 m isobath every 20 NM.
- To train local participants in acoustic survey methodology including fish identification and sampling, scrutinizing of echograms, hydrographic sampling and abundance estimation.
- Conduct a parallel survey with the Senegalese R.V. "Itaf Deme". This includes inter-calibration experiments and comparisons of trawl catches.

The time allocated for this part of the survey, off Senegal and The Gambia, was 9 days.

## 1.2 Participation

Participating scientists were:

Centre de Recherches Océanographiques de Dakar-Thiaroye (CRODT), Senegal:

Serigne Sylla (Senegalese team leader), Moise Biagui, Amadou Fallou Niang And Ibra Fall

Department of Fisheries (FD), The Gambia:

Juldah Jallow (Gambian team leader), Sabena Mendy And Abdoulie Njie

Institut Mauritanien de Recherches Océanographiques et des Pêches (CNROP), Mauritania:

Ibra Diallo

Institut National de Recherche Halieutique (INRH), Morocco:

Lahcen Abouabdela

Centre National des Sciences Halieutique de Boussoura (CNSHB), Guinea:

Amadou I Bah

Institute of Marine Research (IMR), Norway:

Jens-Otto Krakstad (Cruise Leader), Magne Olsen, Thor Egil Johannson and Ole Sverre Fossheim

## 1.3 Narrative

The survey was supposed to start on the 30/10-2005 from Dakar, but the vessel only left port at 12:30 GMT (GMT=local time) on the 31/10 due to technical problems. The survey started at the border between Guinea Bissau and Senegal (240 degree on Cape Roxo, Casamance) at 02:00 the following morning. The Senegalese research vessel “Itaf Deme” started the survey simultaneously from a position 1 nm south of “Dr. Fridtjof Nansen”. The southern border between Senegal and the Gambia ( $270^{\circ}$  at  $13^{\circ}03'N$ ) was reached on the 2/11 at 03:45, while the northern border of the Gambia ( $270^{\circ}$  at  $13^{\circ}35'5''N$ ) was reached on the 1/11, at 23:00. A large detour was taken outside the Saloum River because an international naval exercise blocked our regular survey track. Cape Vert was reached on the 5/11 at 21:00, before the regular survey ended at St Louis at the border to Mauritania on the 7/11 at 21:00. Returning to Dakar an intercalibration exercise was conducted before the vessel returned to port in Dakar on the 8/11 at 15:00. The course track and fishing stations are shown in Figure 1, while

Table 1 shows survey effort during the survey, including number of trawl stations and CTD casts.

During all surveys in the region a common strategy has been adapted with systematic parallel course tracks spaced 10 NM (nautical miles) apart, perpendicular to the depth isobaths. To cover the whole distribution area of pelagic fish, the shelf was covered from the 15 m isobath and offshore to the 500 m isobath. Trawling was done irregularly, either to identify echo registrations or to check ‘blindly’ if fish were mixed with the plankton in the upper layers of the water column. Pelagic trawl with floats was often used to catch fish close to the surface. A smaller pelagic trawl or the bottom trawl with floats was used for sampling pelagic fish in shallow waters (depth less than 25 m).

Four Crossshelf hydrographic transects were carried out, at Casamance, off the Gambia, at Cape Vert and at St. Louis – south.

All data collected during the survey were made available to the participants.

Table 1. Summary of survey effort by regions, including number of demersal (BT) and pelagic (PT) trawl hauls, CTD casts, and distance surveyed (log), disregarding the steaming from Cape Vert to Casamance and from St. Louis to Cape Vert (log).

Area	BT	PT	Total trawls	CTD casts	Log (NM)
Casamance to St. Louis	14	24	38	48	1550

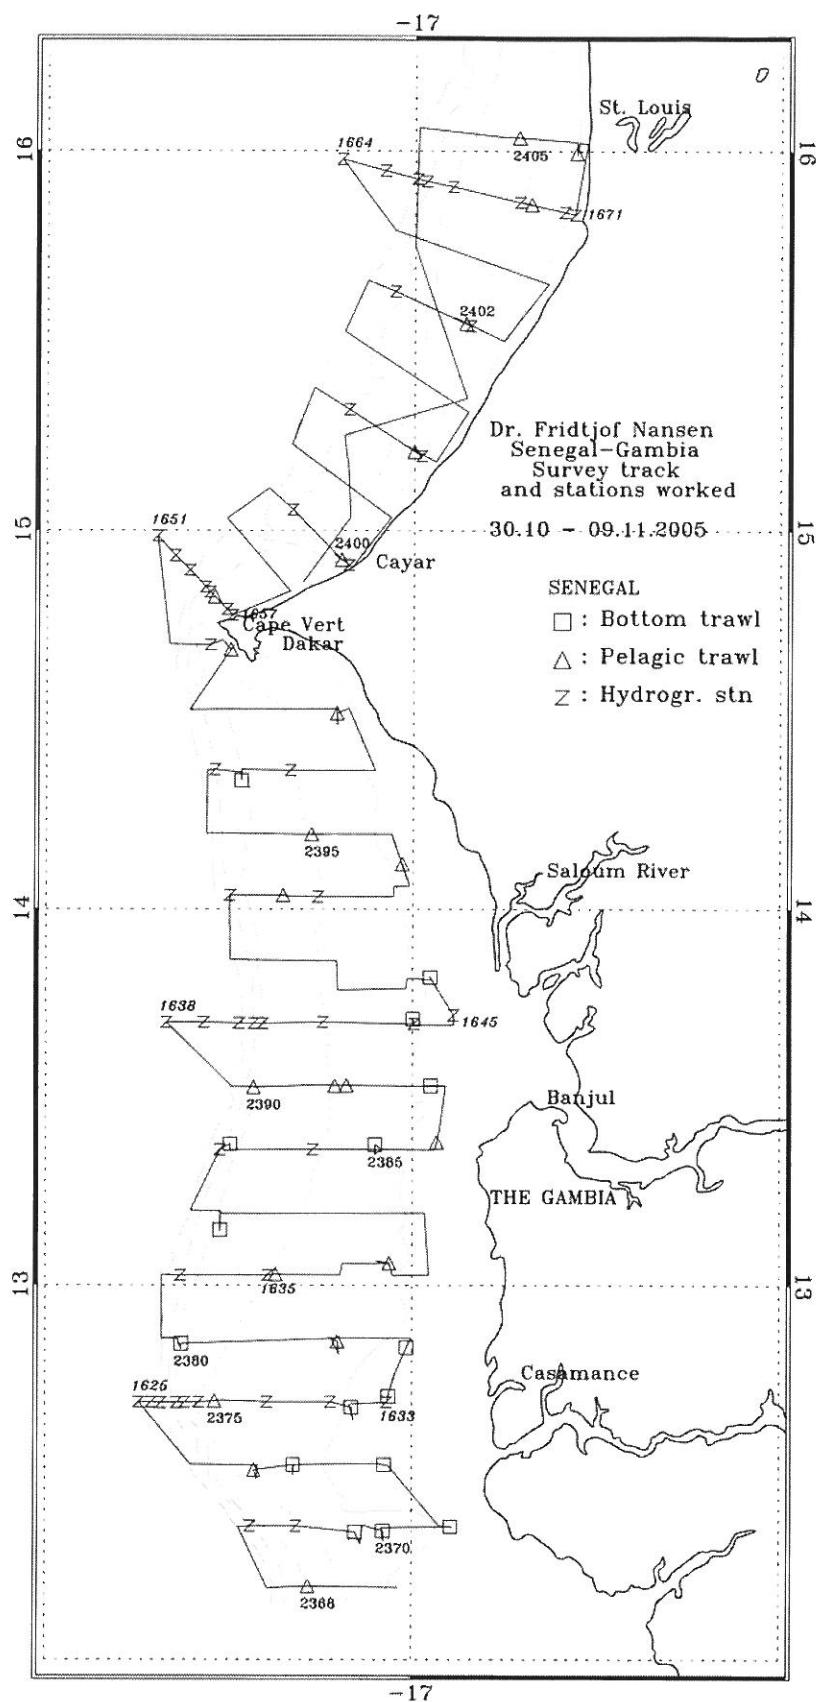

Figure 1. Course tracks with fishing and hydrographical stations; Casamance to St. Louis.

## CHAPTER 2 METHODS

---

### 2.1 Environmental Data

#### *CTD-profiling*

A Seabird 911+ CTD probe was used to obtain vertical profiles of the temperature, salinity and oxygen. Real time logging was carried out using the PC based Seabird Seasave Software. CTD casts were conducted along the cruise track in transects at about every one degree latitude and at fixed stations every 50 m and 200 m depth every 20 NM. The casts were stopped a few meters above the bottom, and at a maximum of 500 m depth. Two water samples, one near the surface and one near the bottom, were collected using *Niskin* bottles at stations corresponding to the standard profiles. The samples were analysed for dissolved oxygen using the Winkler method in order to calibrate the oxygen sensor. Salinity of water samples was used to calibrate the salinity sensor using the Guildline Portasal salinometer. The salinity sensor on the CTD was stable and it was not necessary to apply any correction factor.

The oxygen sensor was calibrated during the survey. A total of 20 samples were accepted for oxygen calibration. A linear regression of the Winkler determinations on the CTD values produced the correction:

$$O_{2\text{corrected}} = a \cdot O_{2\text{recorded}} + b \quad (1)$$

were  $a=1.0504$  and  $b=-0.0581$

#### *Meteorological observations*

Meteorological data logged from the Aanderaa meteorological station included wind direction and speed, air temperature, incident solar intensity and sea surface temperature (SST). All data were averaged by unit distance sailed (1 NM).

#### *Termosalinograph*

The SBE 21 Seacat thermosalinograph was running routinely during the survey. Obtaining samples of sea surface salinity and relative temperature (5 m depth) every 10 sec during the survey.

*Current speed and direction measurements (ADCP)*

The ship-born Acoustic Doppler Current Profiler (ADCP) from RD Instruments was running throughout the survey. The ADCP was set to external trigger, triggered by the EK 500 system. The depth cell interval set to 3 m and the number of cells was set to 120.

## 2.2 Biological sampling

Biological sampling of the fish was carried out using trawls. A pelagic trawl with floats was often used. A smaller pelagic trawl or the bottom trawl with floats was used for sampling the pelagic fish in shallow waters (depth less than 25 m). Annex II gives a description of the instruments and the fishing gear used. All catches were sampled for composition by weight and numbers of each species caught. Species identification was based on the FAO Species Guides. Length frequency distributions, by total fish length in cm, of the selected target species were recorded at all the stations where they were present. Individual weight measurements were taken regularly to estimate the condition factor in the length-weight relationship:

$$\overline{w} = \frac{cond}{100} \cdot L^3$$

The specific condition factors obtained from the samples and applied for this survey were: 0.96 for sardinellas and *Trachurus trecae*.

For the estimation of the biomass of carangids and associated species, an overall average length of 23 cm and a condition factor of 0.88 (to calculate the mean length of this length group) were applied. The target groups used for Senegal and The Gambia can be found in Table 2, while the complete records of fishing stations and catches are shown in Annex I.

Table 2. Allocation of acoustic densities to taxii. Note that for the groups of sardinella, horse mackerel, and sardine all encountered species are listed, while only examples are listed for the remaining groups.

<b>Group</b>	<b>TAXON</b>	<b>Species</b>
Sardinella	<i>Sardinella</i> sp.	<i>S. aurita</i> <i>S. maderensis</i>
Horse mackerel	<i>Trachurus</i> sp.	<i>T. trecae</i> <i>T. trachurus</i>
Sardine	<i>Sardinops</i>	<i>S. pilchardus</i>
Pelagic species 1	Clupeiformes <sub>1</sub>	<i>Ilisha africana</i> <i>Engraulis encrasiculus</i>
Pelagic species 2	Carangidae <sub>2</sub>	<i>Selene dorsalis</i> <i>Chloroscombrus chrysurus</i> <i>Decapterus rhonchus</i> <i>Alectis alexandrinus</i> <i>Euthynnus alletteratus</i> <i>Sarda sarda</i> <i>Scomber japonicus</i> <i>Sphyraena guachancho</i> <i>Trichiurus lepturus</i> <i>Zeus faber</i>
Little tuny	Scombridae	
	Sphyraenidae	
	Others	
Other demersal species	Sparidae <sub>3</sub>	<i>Dentex angolensis</i> <i>D. macrophthalmus</i> <i>D. congoensis</i> <i>D. canariensis</i> <i>D. barnardi</i> <i>Pagellus bellottii</i> <i>Sparus caeruleostictus</i> <i>S. pagrus africanus</i> <i>Pseudupeneus prayensis</i> <i>Brachydeuterus auritus</i> <i>Arioma bondi</i> <i>Pomadasys incisus</i> <i>Galeoides decadactylus</i>
Big-eye grunt	Other taxii

<sub>1</sub>: other than *Sardinops* sp.; <sub>2</sub>: other than *Trachurus* sp.; <sub>3</sub>: main taxon in group.

### 2.3 Acoustic sampling

A SIMRAD EK500 Echosounder was used with the settings as shown in Annex II. The Bergen Integrator (BEI) was used for analysis and allocation of the integrated  $s_A$ -values to the individual specified target groups by 5 NM intervals. The allocation of values to target groups was based on a combination of a visual scrutiny of the behaviour pattern as deduced from echo diagrams, the BEI analysis, and the catch compositions.

In cases where the target category of fish contains more than one species (sardinellas and *Trachurus trecae*), the mean  $s_A$ -value allocated to the category is divided between the species in the same ratio as their contribution to the mean back scattering strength in the length frequency samples.

The following target strength (TS) function was applied to convert  $s_A$ -values (mean integrator value for a given species or group of species in a specified area) to number of fish:

$$TS = 20 \log L - 72 \text{ dB}$$

Which can be converted (see Toresen *et al.* 1998 for details) to the area form (scattering cross sections of acoustic targets):

$$C_{Fi} = 1.26 \cdot 10^6 L^{-2}$$

where  $L$  is total length in 1 cm length group  $i$  and  $C_{Fi}$  ( $\text{m}^{-2}$ ) is the reciprocal back scattering strength, or so-called fish conversion factor. In order to split and convert the allocated  $s_A$ -values ( $\text{m}^2/\text{NM}^2$ ) to fish densities (numbers per length group per  $\text{NM}^2$ ), the following formula was used:

$$\rho_i = s_A \cdot \frac{p_i}{\sum_{i=1}^n \frac{p_i}{C_{Fi}}}$$

where

$\rho_i$  = density of fish in length group  $i$

$s_A$  = mean integrator value

$p_i$  = proportion of fish in length group  $i$

$\sum_{i=1}^n \frac{p_i}{C_{Fi}}$  = the relative back scattering cross section ( $\text{m}^2$ ) of the length frequency sample of the target species, and

$C_{fi}$  = reciprocal back scattering cross section ( $\sigma_{bs}^{-1}$ ) of a fish in length group  $i$ .

The integrator outputs were split in fish groups using a combination of behaviour pattern as deduced from echo diagrams, the BEI analysis and catch composition as described below. The following groups were used for Senegal: 1) sardinellas, 2) horse mackerel, 3) carangids and associated species, and 4) demersal fish.

The above equations show that the conversion from  $s_A$ -values to number of fish is dependent on the length composition of the fish. It is therefore important to get representative length distributions from the stock in the whole distribution area.

When the size classes (of e.g. young fish and older fish) are well mixed, the various length distributions can be pooled together with equal importance. Otherwise, when the size classes are segregated, the total distribution area has to be post-stratified, according to the length distributions, and separate estimates are made for the regions containing fish with equal size.

For a region representing a distribution of a target-specie, the following basic data are needed for the estimation of abundance;

- 1) the average  $s_A$ -value for the region,
- 2) the surface (usually square nautical miles,  $NM^2$ ), and
- 3) a representative length distribution of the fish in the region.

If the targeted fish is a mixture of more than one species, for example sardinellas, a representative distribution of the two, within the region, as shown in the trawl catches, are used. A length distribution representing the number of the two species for each catch will have to be calculated. Thereafter, these distributions have to be normalized to a unit number (usually 100) so they are equally weighted.

A systematic approach to a) divide the  $s_A$ -value between species in a category of fish (e.g. *Sardinella aurita* and *S. maderensis*) and b) produce pooled length distributions of a target species for use in the above equation and c) calculate the biomass estimates for a region, is obtained through the following procedure:

The samples of the species in the category (e.g. sardinellas) are respectively pooled together with equal importance (normalized).

The mean back scattering strength ( $\rho/s_A$ ) of each length frequency distribution of the target species is calculated and summed. This is automatically done in the Excel spread-sheet made available for acoustic abundance estimation onboard RV "Dr. Fridtjof Nansen", provided the data are punched in this sheet.

The mean  $s_A$ -value allocated to the category of fish in the region is divided between the species in the same ratio as their relative contribution to the mean back scattering strength of the length groups in the sample representing the region

The pooled length distribution is used, together with the mean  $s_A$ -value, to calculate the density (numbers per square NM) by length groups and species, using the above formula. The total number by length group in the area is obtained by multiplying each number by the area. The numbers are then converted to biomass using the estimated weight at length.

#### **2.4 Parallel survey with R.V. “Itaf Deme”**

During the survey the Senegalese research vessel “Itaf Deme” did a parallel survey with “Dr. Fridtjof Nansen”. As part of this, parallel trawl hauls were conducted with regular intervals, as well as acoustic intercalibration between the vessels. The strategy for the intercalibration followed the recommendations by MacLennan and Simmons (1992).

One research vessel placed itself 0.5 NM behind and 0.5 NM to the side of the other vessel that took the lead. The distance between the vessels were chosen so that the vessels could stay as close together as possible without disturbing each other’s acoustic recordings. Starting time and log were recorded onboard each vessel and the distance between vessels was kept constant during the experiment.

All data collected during the parallel survey and intercalibration will be analysed on land and a separate report will be produced from the exercise.

## CHAPTER 3 SURVEY RESULTS

---

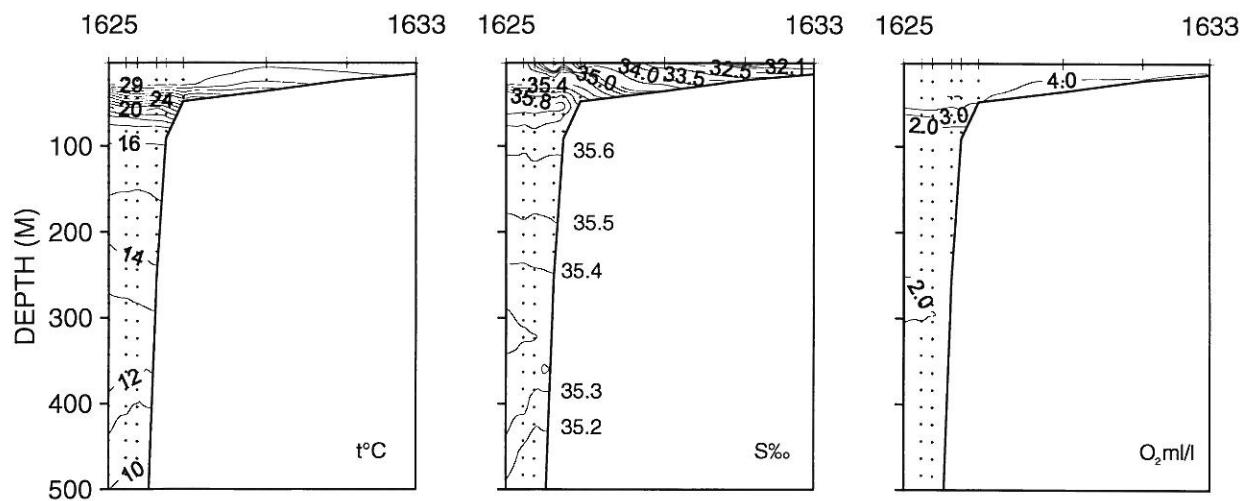

### 3.1 Hydrography

Hydrographical data was collected on fixed CTD stations to 500 m depth and from the Thermosalinograph and the Aanderaa weather station that continuously collect sea surface temperature, wind speed and direction, solar radiation, etc. during the survey.

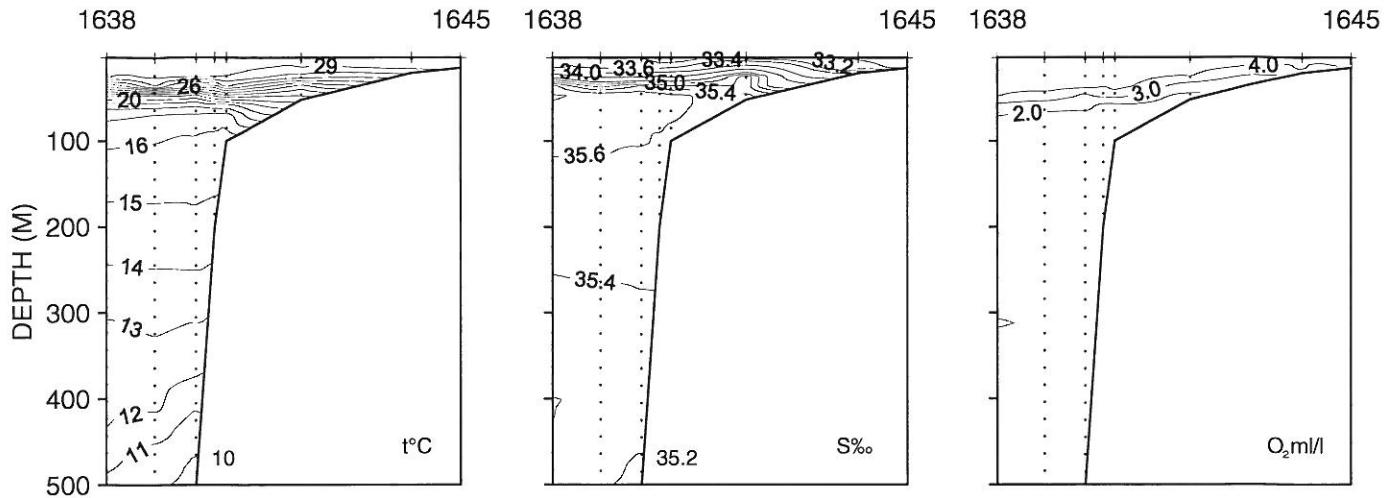

#### *Cross shelf hydrographical profiles*

Figure 2 shows the distribution of temperature, salinity and oxygen from the four hydrographical transects collected during the survey. The situation was similar to last year. The temperature layers were clearly stratified, with warm surface waters and a thermocline around 30-50 m depth. And minimum temperature of 11°C was observed around 500 m depth. Slightly more mixed conditions were experienced inshore at St. Louis. The salinity profiles showed strong influence of freshwater inshore, particularly in the Casamance area and off St. Louis. Maximum salinities were experienced at the shelf break around 100 m depth, with maximum salinities between 35.6 ‰ to 35.8 ‰. Salinity around 500 m was around 35.2 ‰. The water masses in the survey area was well oxygenated with oxygen concentrations in the surface layer >4 ml O<sub>2</sub>/l decreasing to 2.0 ml/l oxygen between 50 – 100 m depth.

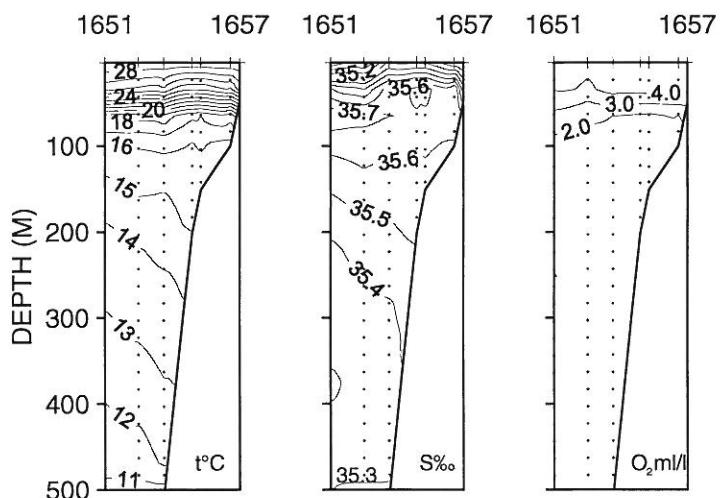

#### CASAMANCE

## THE GAMBIA WEST

## CAPE VERT

## ST. LOUIS - SOUTH

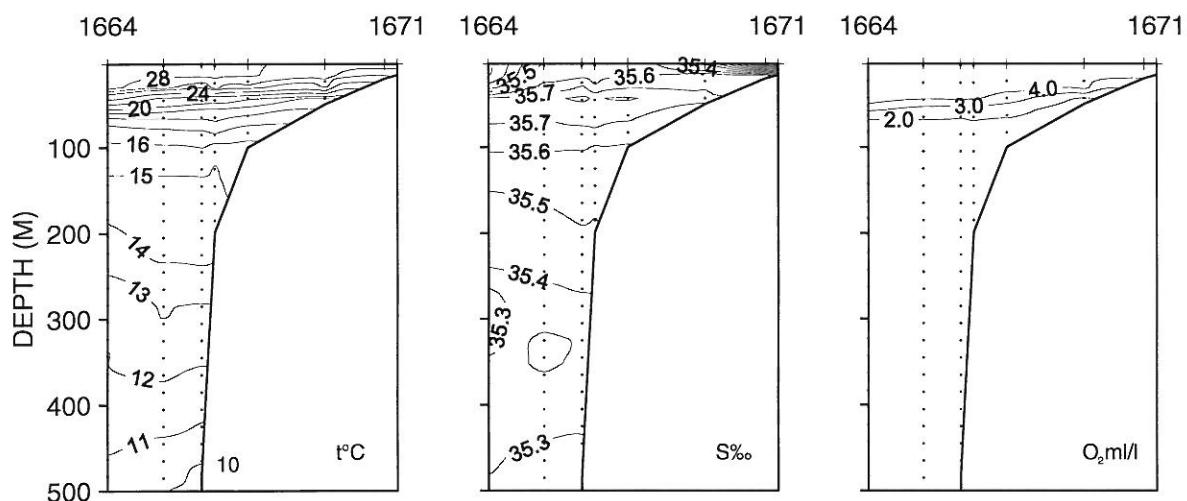

Figure 2. Hydrographical profiles with distribution of temperature, salinity and oxygen off Casamance,  $13^{\circ}40'N$   
- The Gambia, c) Cape Vert, St. Louis - South

### *Along shelf profiles*

Along shelf profiles of temperature, salinity and oxygen was created from the 200 m depth CTD stations collected at every 20 NM during the survey. Only the temperature plots are shown in Figure 3. The figures show the relatively high sea surface temperature especially in the area between St. Louis and Cape Vert ( $29^{\circ}\text{C}$ ), and the intrusion of cooler water masses at St. Louis.

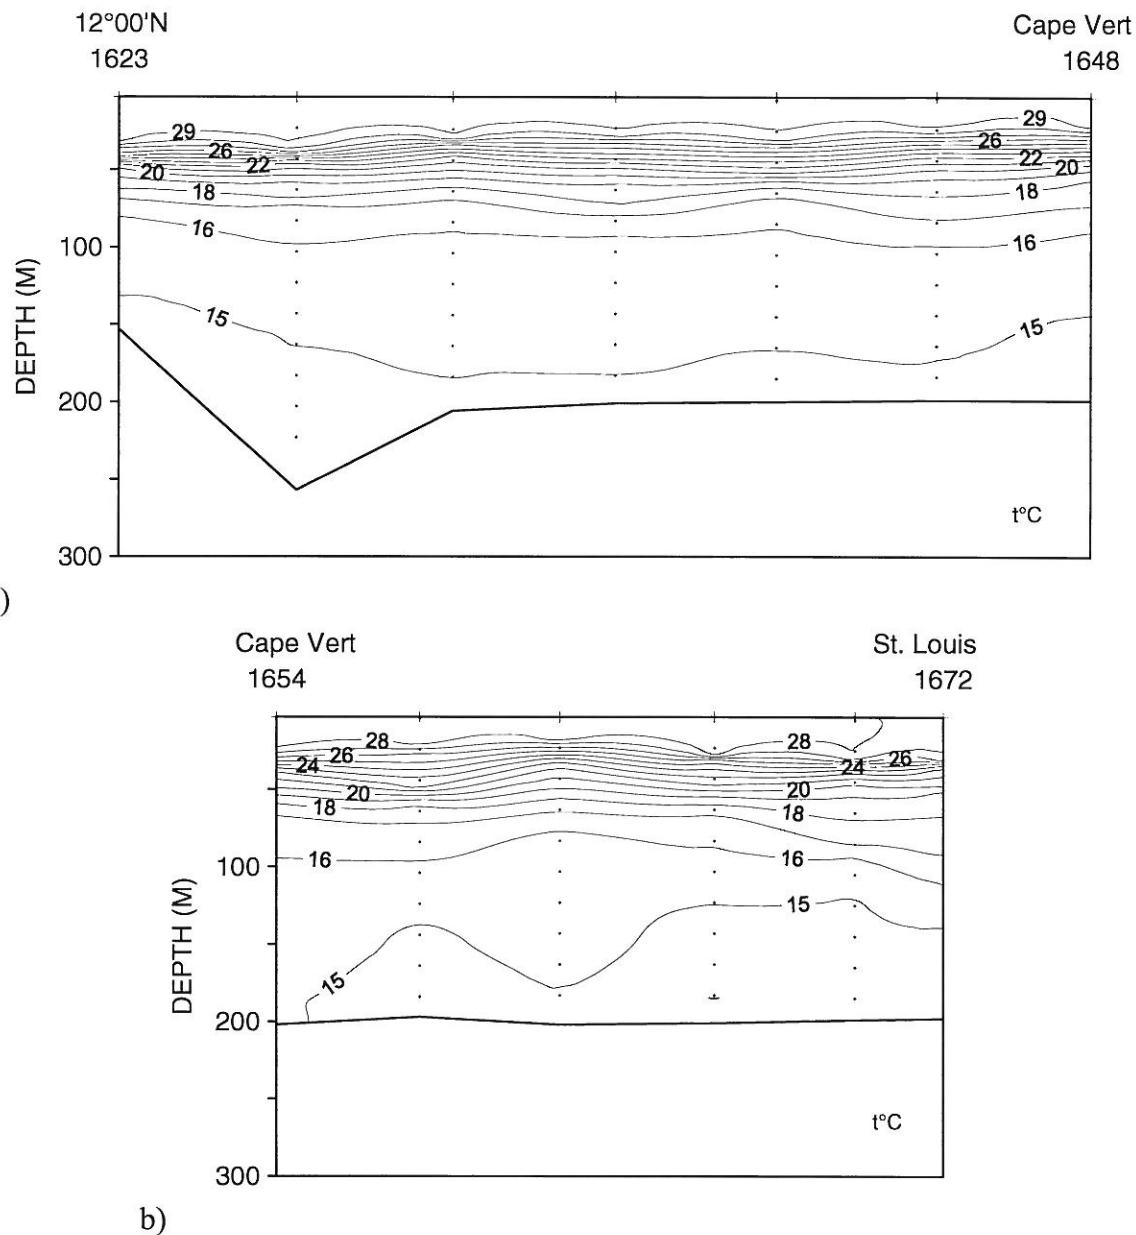

Figure 3. Alongshelf temperature at 200 m depth from a) Casamance to Cape Vert b) Cape Vert to St. Lois.

### *Sea surface temperature, salinity and wind direction*

Figure 4 illustrates the sea surface temperature at 5 m depth, Figure 5 shows the sea surface salinity at the same depth, while Figure 6 show the wind direction and wind speed during the survey of Senegal and the Gambia.

The sea surface temperature in south of Dakar to Casamance was dominated by water masses warmer than 29°C. The warmest water masses was found along the coast (30°C) extending offshore in three large filaments with water temperatures >29.5°C. North of Cape Vert temperatures dropped slightly to 28.5°C. In the northernmost part of the survey area and inshore along the coast from St. Louis cooler water masses was experienced with temperatures down to 27.5°C outside St. Louis. Last year was warmer than normal, particular in the northern part of Senegal. This year similar temperatures to what was observed in 2004 were experienced.

The Casamance shelf was dominated by relatively low salinity, typically around 31.0‰ – 32.0‰. A large frontal zone separating the less saline shelf water from the more saline water masses offshore was observed at the shelf break, maximum salinity in this area was 34.4‰. Further north a gradual increase in salinity is observed between The Gambia and Cape Vert. The salinity at Cape Vert is around 34.4‰. In the northern part of the survey area salinity between 34.6 and 34.8 is observed. Except at St. Louis where local river discharge reduce the salinity to <34‰. Offshore from St. Louis an intrusion of more saline water masses from the north can be observed, with salinity >35‰. Compared to last year more rain has been experienced in the survey area and shelf salinity is thus less than normal.

Little wind was experienced in the area on the Casamance shelf, and the wind direction was shifty. The wind increased around Cape Vert to an average of approximately 21 - 22 knots for the rest of the survey period. The dominant wind direction in this region was from the north and generally conditions were similar to last year. The conditions were favourable for acoustic surveying throughout the survey.

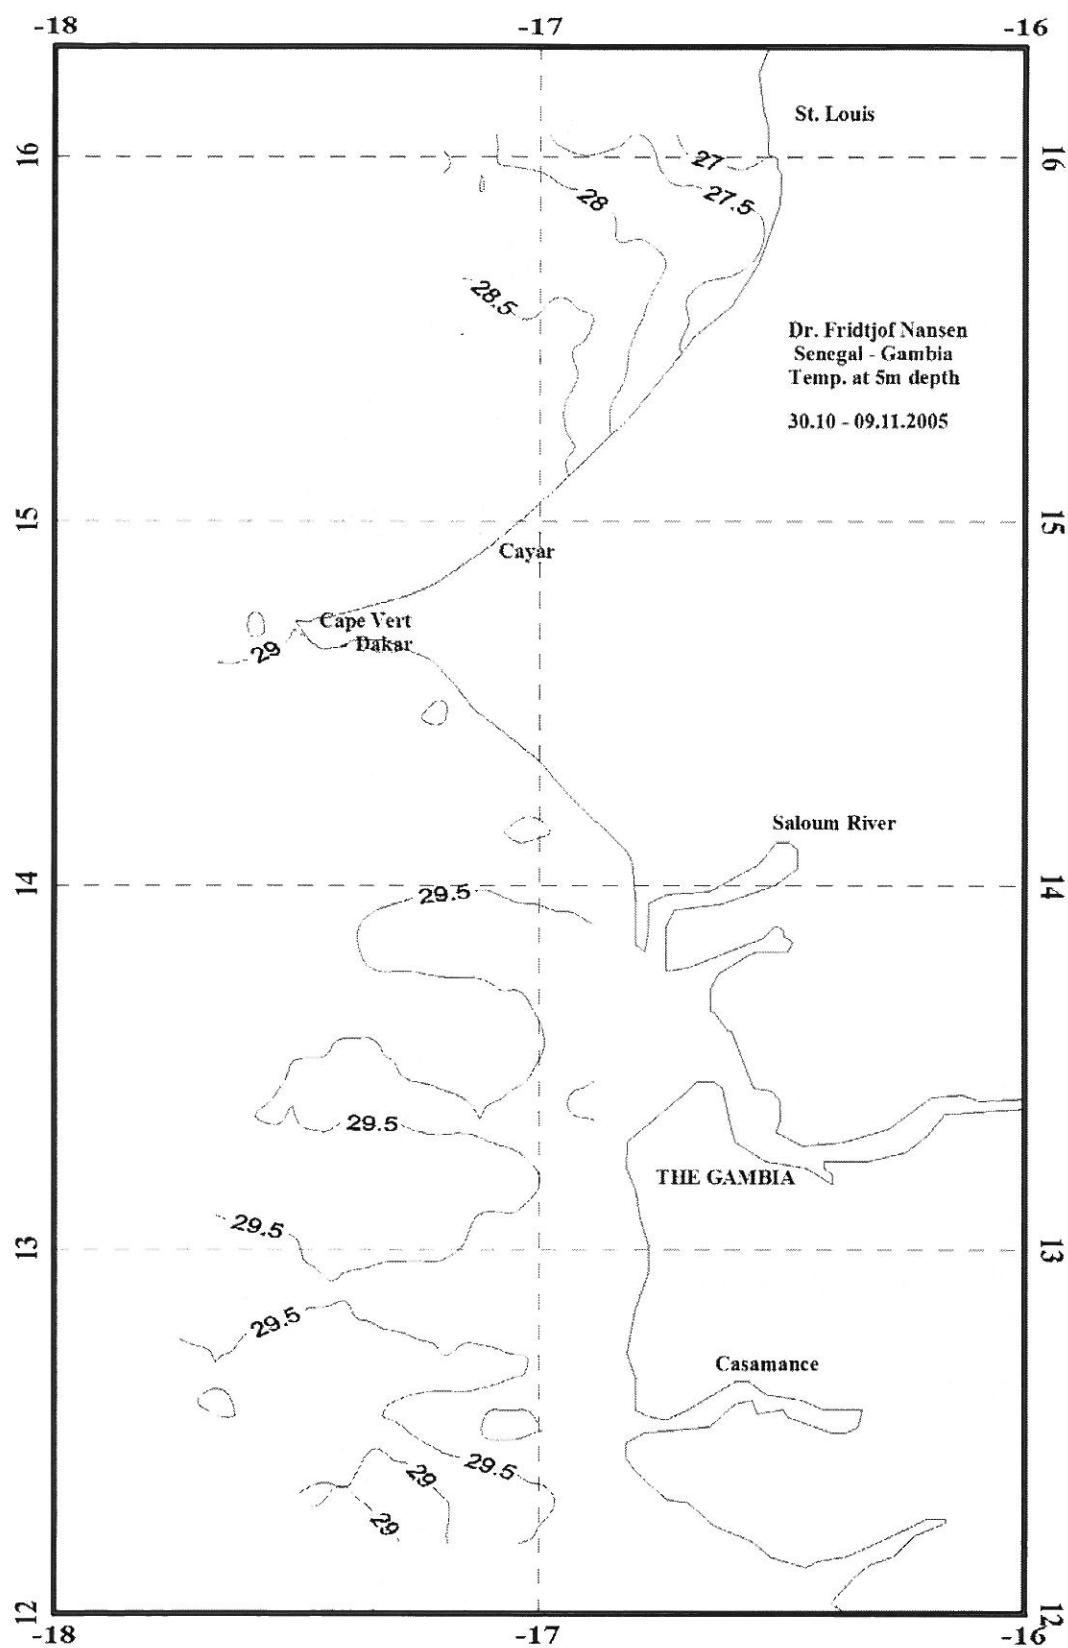

Figure 4. Sea surface temperature; Casamance to St. Louis.

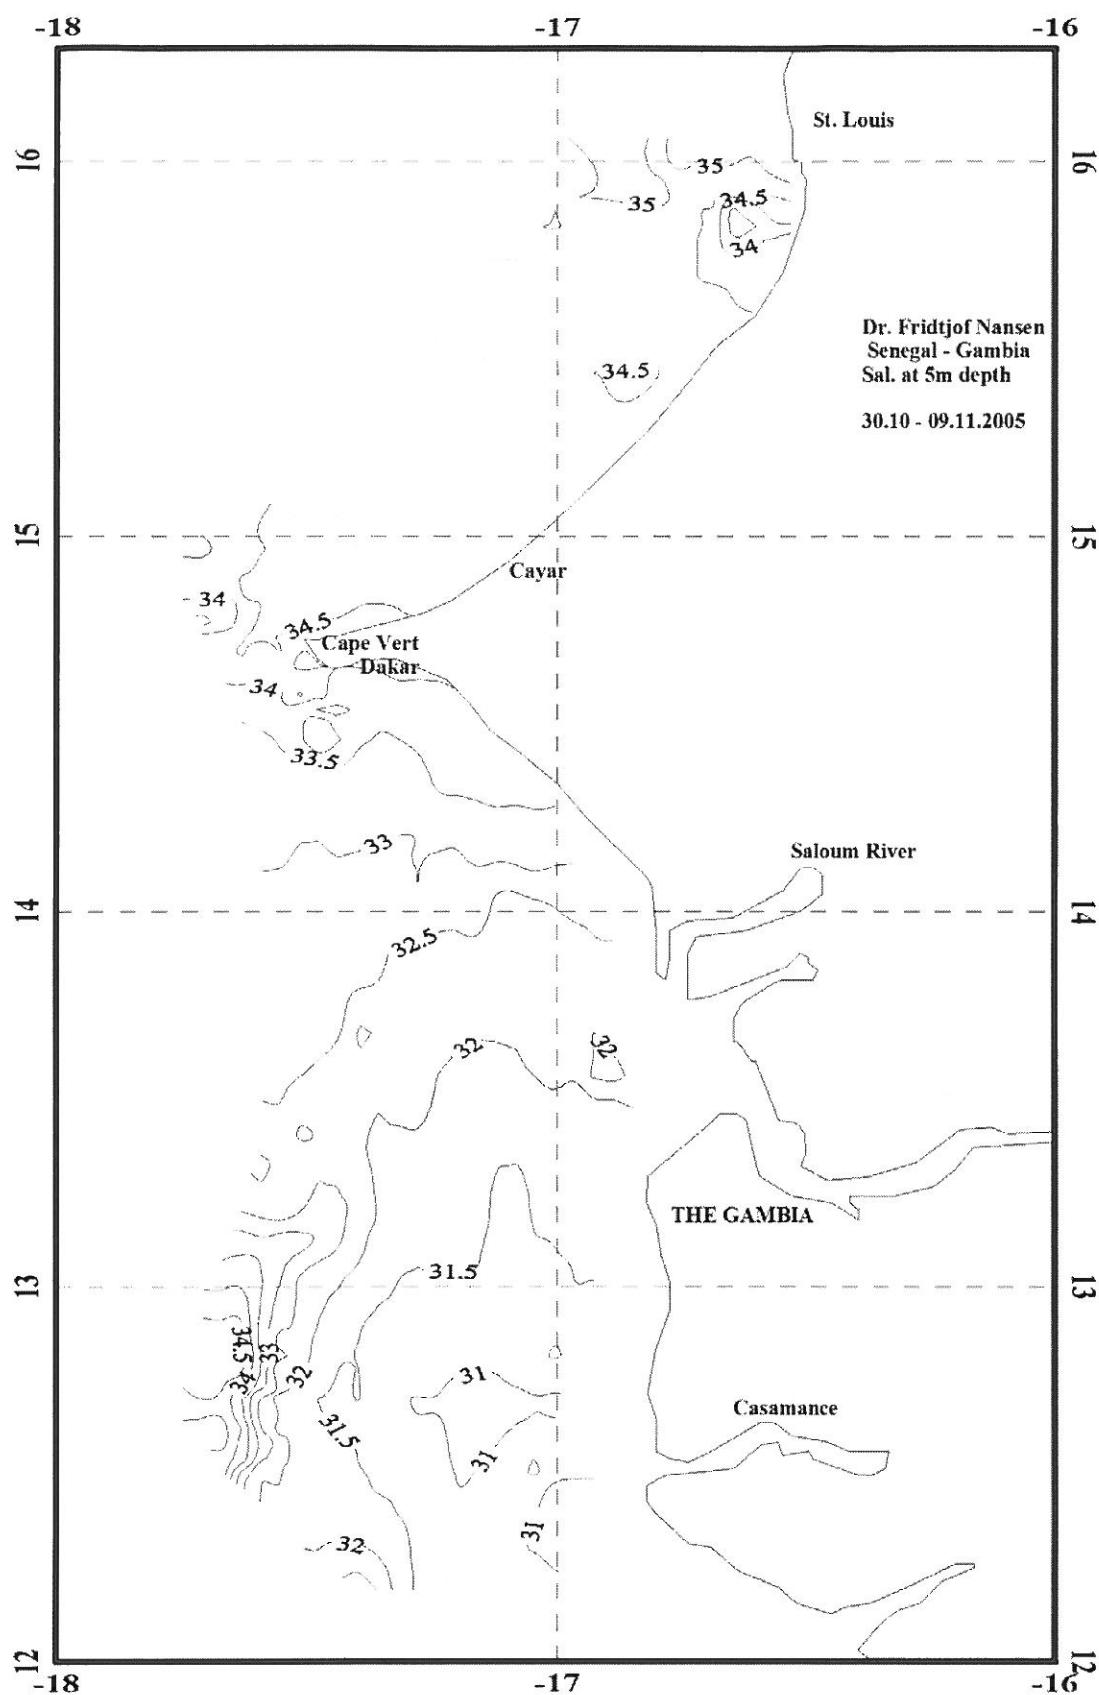

Figure 5. Sea surface salinity; Casamance to St. Louis.

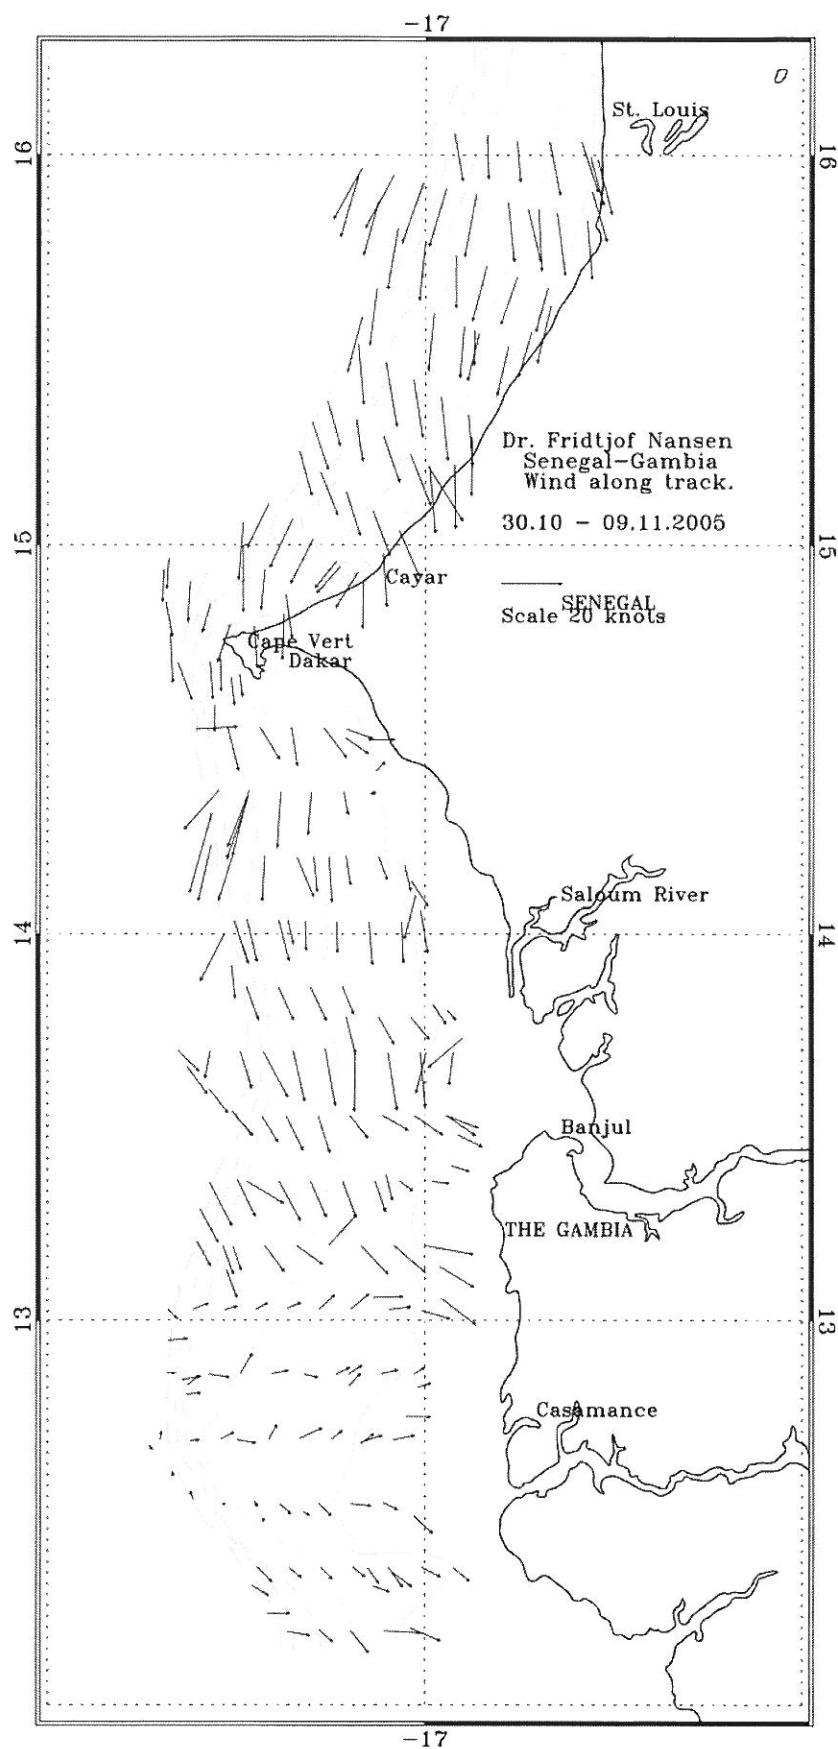

Figure 6. Wind speed and direction; Casamance to St. Louis.

### 3.2 The Casamance shelf

The main groups of pelagic fish encountered during the survey of Senegal and the Gambia illustrated with contoured acoustic densities are seen in Figure 7, Figure 8 and Figure 9.

The distribution of pelagic fish on the Casamance shelf reflected the low salinity shelf water. The shelf was abundant with clupeid fish also this year. *Ilisha africana* was particularly frequent in trawl catches close to the coast on the southern part of the shelf, anchovy, *Engraulis encrasicolus* were also found in one trawl catch in the same area. However, abundance estimates were only calculated for the sardinella species.

The distribution of sardinella was mainly inshore of 20 m depth in the southern part of Casamance, extending further offshore towards the 50 m isobath further north on the shelf. Dense concentrations were found around the 20 m isobath. A break in the sardinella concentrations was found in the southern part of the survey area, and there was no continuity in registration into Guinea Bissau. Figure 7. The region was dominated by *S. maderensis*, and *Sardinella aurita* only contributed approximately 9% to the biomass.

Two modal peaks of *Sardinella aurita* were found in the area, one at 24 cm, and one at 27 cm (total length) while the modal size of *S. maderensis* was 23 cm. Estimated number and biomass by length-groups can be found in Annex IV. The total biomass of sardinellas in the area was estimated to be 220 thousand tons, Table 3. Of this 19 thousand tons were *S. aurita*, while 201 thousand tons were *S. maderensis*. Last year the total biomass of sardinellas in the area was estimated to be 366 thousand tons, of this 32% were *S. aurita*.

Like the two previous years, no *Trachurus trecae* were found in the Casamance area. *Decapterus rhonchus* were found in low concentrations on the shelf break and inside of the 20 m isobath in the northern part of the Casamance area. The biomass of *Decapterus rhonchus* was 3.3 tons, and the average length in the area 28 cm.

Other pelagic fish (P2) were covering large parts of the shelf, similar to what is experienced most years. In general both carangids, other than horse mackerel and *Decapterus rhonchus*, scombrids, hairtails and barracudas were found in the area,

Table 4. The most frequently found species in the catches were *Chloroscombrus chrysurus*, *Alectis alexandrinus*, *Trichiurus lepturus*, *Sphyraena guachancho* and *Scomberomorus tritor*. The species were well mixed with the sardinellas where their distribution overlapped, Figure 9. The estimated biomass of this group of fish was 59 thousand tons compared with 58000 tonnes last year.

### 3.3 The Gambian shelf

The distribution of sardinellas from the Casamance area continued into the Gambian waters with dense to very dense concentrations from 15-30 m bottom depth, especially in the northern part of the survey area, and scattered concentrations offshore between 50 and 100 m isobath. Figure 4. Both species of sardinella was found across the whole distribution area, with no clear depth separation between the species, but with *S. maderensis*, dominating in biomass by 72%. The total estimate of sardinellas in the Gambian waters during the survey was 261 thousand tons, Table 5. This comprised of 188 thousand tons of *S. maderensis* and 73 thousand tons of *S. aurita*. Last year a total of 128 thousand tons sardinella were found in this region, and 16% of this were *S. aurita*. The modal length of *S. maderensis* was 24 cm while catches of *S. aurita* in the area showed three modal peaks at 21 cm, 24 cm and 27 cm. The estimated numbers and biomass by length-groups can be found in Annex IV.

*Trachurus trecae* was found on the shelf break at 100 m depth extending inshore across the 50 m isobath. The distribution area continues with the distribution of *Decapterus rhonchus* at the Casamance shelf, Figure 8. The densities were low with an estimated biomass of 0.8 thousand tons of *Trachurus trecae*, and 3.6 thousand tons of *Decapterus rhonchus* Table 5. The size distribution of horse mackerel in the area consisted of one modal peaks at 23 cm. Last year 29 thousand tons were found in this area.

Carangids and associated species were found in low to medium density widely distributed over the whole Gambian shelf, Figure 9. The catches of this group were dominated by *Chloroscombrus chrysurus*. The biomass was estimated at 55.8 thousand tons.

### 3.4 The Gambian border - Cape Vert

Sardinella was distributed in two areas between The Gambian border and Cape Vert. Very dense concentrations were found inshore around the 20 m isobath extending across the border from The Gambia to north of the Saloum River entrance. Scattered concentrations were found offshore to 80 m depth, and northwards from this area. Another distribution area with scattered sardinella was found north of this with dense concentrations in the northernmost part of the region at around 20 m depth, Figure 7. Table 7 shows the biomass estimates of the two sardinella species, *S. aurita* was the most dominant contributing 56% of the total biomass of 339 thousand tons. *S. maderensis* was estimated at 148 thousand tons while 191 thousand tons of *S. aurita* was found. Last year 262 thousand tons of Sardinella was found in the region, of this *S. maderensis* contributed with 59%.

Pooled length compositions of samples from *S. maderensis* showed a modal peaks at 24 cm, while the *S. aurita* had modal peaks at 21 cm, 24 cm and 27 cm. Estimated number and biomass by length-groups are found in Annex IV.

*Trachurus trecae* was found from the Gambian border to Cape Vert around the 100 m isobath extending inshore to <50 m bottom depth and mixing with *Decapterus rhonchus* in its distribution area. The distribution is similar to what has previously been observed at this time of the year, but the density was lower than usual, Figure 8. The total biomass was estimated at 12 thousand tons, of this *Trachurus trecae* contributed with 7 thousand tonnes and *Decapterus rhonchus* with 6 thousand tons, compared with 33 thousand tonnes of horse mackerels last year. The distribution of *Trachurus trecae* showed four modal peaks in the area, at 11, 18, 24 and 27 cm, while the *Decapterus rhonchus* showed two modal peaks, at 23 and 28 cm.

As during previous years in the other regions south of Cape Vert, carangids and associated pelagic species were distributed over most of the shelf from less than 20 m depth and offshore to between 50 and 100 m depth. The dominating species from this group in the area were *Chloroscombrus chrysurus*, *Scomber japonicus* and *Sphyraena guachancho*, Figure 6 and Table 8. The carangids and associated pelagic fish species were very scattered in the region, and the biomass was estimated at about 26 thousand tonnes, Table 7, compared to the 79 thousand tons estimated last year.

### 3.5 Cape Vert - St. Louis

Sardinellas were very scattered in the region between Cape Vert and St. Louis. Small concentration of *S. maderensis* only were found in a narrow band along the 20 m isobath, Figure 7. No *S. aurita* was found in the region. The modal length of *S. maderensis* in the area was 26 cm and the biomass estimate was 8 thousand tons, Table 9. Last year 25 thousand tons of *S. aurita* was found in this region together with 39 thousand tons of *S. maderensis*.

Scattered concentrations of *Trachurus trecae* were found in one continues region from south of the Cayar canyon to St. Louis, with slightly higher concentrations in the southern part of the area around Cayar. The distribution extended from approximately 100 m depth to between 50 and 20 m bottom depth. *Decapterus rhonchus* was found mixed with the *Trachurus trecae* in the same region but with a more shallow distribution. *Trachurus trecae* in the region had four modal peaks, at 11 cm 22 cm, 26 cm and 31 cm. No length frequencies from *Decapterus rhonchus* were obtained from the area so the biomass for this species were based on the average length from the number and weight in the trawl catches. The biomass of *Trachurus trecae* was thus estimated to be 73 thousand tonnes, while *D. rhonchus* was found to be 24 thousand tons. Last year the biomass of horse mackerels in this area were estimated

to be 15 thousand tonnes. The increase may possibly be attributed to local changes in distribution pattern and shift of fish northwards.

A low density region of Carangids and associated pelagic fish species were found from North of the Cayar Canyon at 20 m depth, extending offshore across the 50 m isobath further north. The dominant species in the catches were *Chloroscombrus chrysurus* and *Trichiurus lepturus* and the biomass was estimated to be 11 thousand tons compared with 20 thousand tons in 2004.

### 3.6 Parallel trawl survey

The parallel trawl survey was conducted successfully. During the whole survey of Senegal the Itaf Deme followed the course track of "Dr. Fridtjof Nansen". As part of the parallel trawl survey several rounds of intercalibration and comparative trawl hauls between the vessels were conducted successfully. The data from the parallel survey will be analysed later and presented in a separate report. Due to a problem with the hydraulic system onboard Dr. Fridtjof Nansen it was not possible to conduct parallel trawling on the shelf outside Dakar as was planned at the beginning of the survey.

## CHAPTER 4 OVERVIEW AND SUMMARY OF RESULTS

---

The survey was conducted successfully from 30<sup>th</sup> October to 9<sup>rd</sup> November, covering a course track of approximately 1550 NM, including the steaming to and from the survey area to Dakar. A total of 38 fishing stations and 48 CTD casts were established.

The hydrographical data showed a stable surface layer at approximately 30-50 m depth for the whole shelf south of Cape Vert. Warm low salinity surface waters characterized the surface water in the Casamance area and the Gambia. The low salinity can be attributed to discharge from the rivers in the area. The shelf from Cape Vert and north to St. Louis was warmer than usually during the October - November survey and intrusion of cold water from the north was only visible at St. Louis. The shelf was well oxygenated in the whole survey area. The situation was similar to what was observed last year, but the low shelf salinity was even more pronounced due to heavy rain in the region.

The main concentration area for sardinella was the Casamance shelf and The Gambian coast, 83% of all the sardinella in the survey area was found in this region. Two other concentration areas were found north of this, between Saloum River and Dakar, and in a narrow band along the coast between Cayar and St. Louis. The main concentrations in all three areas were found along the 20 m isobath. The total biomass was estimated to be 828 thousand tons, and 33% of this was *S. aurita*, Figure 7. As usual *S. aurita* was more predominant in deeper and more saline waters than *S. maderensis*. The division of biomass between length groups and species are dependent on representative trawl samples of the two species. Since sardinella show strong trawl avoidance some care should be taken when interpreting the results.

Horse mackerels including the false scad *Decapterus rhonchus* were found in two areas along the shelf break at 100 m depth between the southern border of The Gambia and Cape Vert. The distribution extended inshore beyond the 50 m isobath in some parts of the southern shelf. The main distribution area of the horse mackerel was the northern shelf of Senegal between the Cayar Canyon and St. Louis, Figure 8. *Trachurus trecae* dominated along the shelf edge in the whole distribution area, while *Decapterus rhonchus* became more abundant inshore, and particularly on the southern shelf. The total estimate of *Trachurus trecae* was 81 thousand tonnes, or 69% of the total, while the biomass of the *Decapterus rhonchus* was estimated to be 36 thousand tons. 90% of the *Trachurus trecae* was found north of cape Vert. A larger proportion of *Decapterus rhonchus* was found on the southern shelf, but 67% of the estimate biomass was still found north of Cape Vert.

The ‘P2’s’, other carangids and associated species, were distributed over most of the shelf in low densities, Figure 9. The main species in the catches of this group consisted of *Chloroscombrus chrysurus*, *Sphyraena guachancho*, *Trichiurus lepturus* and *Selene dorsalis*. The total biomass of this group was estimated at approximately 115 thousand tons. The species in this group was mixed with dense concentrations of plankton, other pelagic fish species and in particular the *Brachydeuterus auritus*. Thus, division on acoustic energy on different targets in these groups must be done with care.

An overview of the acoustic estimates of biomass of the main groups of pelagic fish is shown in Table 11, and the geographical distribution and abundance of main species can be found in Figure 10. The total biomass of sardinellas was thus 828 thousand tonnes, horse mackerels 116 thousand tons and of carangids and associated species 115 thousand tons.

Table 11. Summary of biomass estimates of pelagic fish, Senegal and the Gambia. Values in tonnes.

	<i>S. maderensis</i>	<i>S. aurita</i>	Horse mackerel	Carangids etc.
St. Louis-Cape Vert	8	-	97	11
Cape Vert - the Gambia	148	191	12	26
The Gambia	188	73	4	19
Casamance	201	19	3.	59
Total	545	283	116	115

Table 12 lists biomass estimates of sardinellas and carangids (including *Trachurus trecae*) and associated species from the “Dr. Fridtjof Nansen” surveys of the shelf region.

Large-scale latitudinal movements of pelagic fish between West Sahara and Guinea Bissau are well known, and in the summer the sardinellas should be concentrated in Senegal for spawning. The biomass estimate of sardinella from this year is almost exactly the same as last year, and fits well within the time series of increasing sardinella abundance since 1996. The species distribution and species composition of the two species were also similar to last year. The estimate of *Trachurus trecae* from this year, 81 thousand tons, is only slightly higher than the 76 thousand tons estimated last year. *Decapterus rhonchus* was included in the P2 estimate estimated last year, but due to requests from the region it has now been separated again. The biomass estimate of this species was 36 thousand tons. The total estimate of carangids and associated species was estimated at 115 thousand tons. This is much lower than the 212 thousand tons found during the October – November survey last year, and is possibly an underestimate of the biomass of this group due to the frequent mix of fish from this group with large concentrations of *Brachydeuterus auritus* and plankton in the survey area.

## RÉSUMÉ

La campagne a été conduite avec succès durant la période du 30 octobre au 9 novembre selon un parcours d'une longueur approximative de 1550 milles nautiques incluant les temps de route à partir de/et vers Dakar. Au total, 48 stations de pêche de contrôle ont été réalisées.

Les données hydrographiques révèlent une stabilité de la température des eaux de surface autour des 30-50 m de profondeur, pour toute la zone au sud de Dakar. Les eaux de surface en Casamance et en Gambie se caractérisent par une température relativement élevée et une faible salinité. La côte du Cap-Vert au Nord de St-Louis a été plus chaude que d'habitude à la même époque et l'influence des eaux froides du nord n'apparaît qu'à partir de St-Louis. Les eaux étaient dans l'ensemble bien oxygénées sur toute l'étendue couverte. La situation en présence est similaire à celle observée l'année dernière, mais la faiblesse de la salinité est plus prononcée due aux fortes pluies enregistrées cette année,

Les sardinelles ont été rencontrées principalement dans sur la côte en Casamance et en Gambie, où 83% du total des sardinelles durant cette campagne a été trouvée. Deux autres zones de concentration ont été rencontrées au nord de la Gambie, entre le fleuve Saloum et Dakar, et sur une étroite bande le long de la côte entre Cayar et St Louis. L'essentiel des concentrations sur les trois principales zones ont été trouvées le long de l'isobathe des 20 mètres. La biomasse totale a été estimée à 828 milles tonnes, dont 33% de *S. aurita*. Comme très souvent observé, la *S. aurita* a été en général rencontrée dans les eaux plus profondes et plus salées que la *S. maderensis*.. La répartition de la biomasse en classes de tailles et espèces dépendent des échantillons représentatifs des deux espèces lors des opérations de pêche. Du moment que la sardinelle présente un fort taux d'évitement à l'approche du chalut, ces résultats doivent être interprétés avec précautions.

Les chincharts, aussi bien le noir que le jaune *Decapterus rhonchus*, ont été rencontrés essentiellement dans deux zones longeant la limite du plateau continental sur l'isobathe des 100 mètres, l'une au sud de la Gambie et l'autre sur la Petite Côte. Leur distribution s'étend vers la côte jusqu'à l'isobathe des 50 mètres sur quelques parties de la côte. La principale zone de concentration a été la côte Nord entre le canyon de Cayar et St. Louis, Figure 8. Le *Trachurus trecae* a été plus abondant au large dans toute la région, tandis que le *Decapterus rhonchus* est plutôt abondant sur la côte, en particulier sur la côte sud.. La biomasse totale des *Trachurus trecae* est évaluée à 81 milles tonnes, soit 69% de la biomasse totale, tandis que la biomasse des *Decapterus rhonchus* est évaluée à 36 milles tonnes.. 90% des *Trachurus trecae* ont été trouvés au nord de Dakar. Une proportion plus importante de *Decapterus rhonchus* a été trouvée sur la côte sud , mais 67% de la biomasse estimée reste concentrée au nord de Dakar.

Les autres carangidés et espèces associées sont régulièrement distribués sur toute la côte avec des densités relativement faibles,. figure 9. Les espèces principalement capturées ont été *Chloroscombrus chrysurus*, *Sphyraena guachancho*, *Trichiurus lepturus* and *Selene dorsalis*. La biomasse totale est estimée à 115 milles tonnes. Les espèces dans ce groupe ont été mélangées avec du plancton très dense, et avec d'autres espèces pélagiques en particulier le *Brachydeuterus auritus*. Par conséquent, l'allocation des valeurs d'intégration aux différents groupes doit être entreprise avec beaucoup d'attention.

Le tableau 11 ci-dessous résume la biomasse pour chaque groupe de pélagiques ; la répartition géographique et l'abondance de ces espèces sont présentées en figure 10. Ainsi, la biomasse totale des sardinelles s'élève à 818 milles tonnes, celles de chincharts à 116 milles tonnes et les carangidés et espèces associées sont estimées à 115 milles tonnes

Le tableau 12 récapitule les biomasses totales estimées depuis 1981 par le N/O Dr Fridtjof Nansen; il s'agit de l'ensemble des sardinelles, chincharts, carangidés et associées sur les cotes sénégambiennes

Il est maintenant bien connu de l'existence dans la sous région de flux migratoires à grande échelle de poissons pélagiques entre le Sahara de l'Ouest et la Guinée Bissau, et le repli des sardinelles vers le Sénégal en période chaude pour assurer la reproduction. La biomasse estimée pour les sardinelles cette campagne est presque identique à celle trouvée l'année dernière à la même période, et s'inscrit bien dans la série ascendante des biomasses trouvées pour les sardinelles depuis 1996. La distribution et la composition des espèces pour les deux sardinelles sont également similaires à celles de l'année dernière. Le *Decapterus rhonchus* a été inclus dans les P2 dans les estimations de l'année dernière, mais sur demande des scientifiques de la sous région, il a été séparé à nouveau . La biomasse estimée pour cette espèce a été de 36 milles tonnes, Les carangidés et autres espèces associées ont été estimés à 115 milles tonnes. Ceci est nettement inférieur aux 212 milles tonnes trouvées en octobre-novembre de l'année dernière, et pourrait être due à une sous-estimation de ce groupe compte tenu du mélange fréquent de ces espèces avec les fortes concentrations de *Brachydeuterus auritus* et de plancton dans la zone.

## Annex II Description of instruments and fishing gear

The Simrad EK-500, 38 kHz scientific echosounder was used for abundance estimation during the survey, in addition data from the 18 kHz, 120 kHz and 200 kHz transducers were recorded for possible future multifrequency target identification. The Bergen Echo Integrator system (BEI) recorded the hydroacoustic data and was used to scrutinize the acoustic records, and to allocate integrator data to fish species. All raw data were stored to tape and brought back to IMR for storing.

The details of the settings of the echosounders were as follows:

### **Transceiver 1 menu**

Transducer depth	5.5 m
Absorption coeff.	10 dB/km
Pulse length	medium (1ms)
Bandwidth	wide
Max power	2000 Watt
2-way beam angle	-21.0 dB
SV transducer gain	26.91dB
TS transducer gain	27.05
Angle sensitivity	21.9
3 dB beamwidth along.	7.0
3 dB beamwidth athw.	6.9
Alongship offset	0.01
Athwardship offset	0.02

### **Transceiver 2 menu**

Transducer depth	5.5 m
Absorption coeff.	38 dB/km
Pulse length	long (1ms)
Bandwidth	narrow
Max power	1000 Watt
2-way beam angle	-20.6 dB
SV transducer gain	25.95dB
TS transducer gain	26.00dB
Angle sensitivity	21.0
3 dB beamwidth along.	7.2
3 dB beamwidth athw.	7.0
Alongship offset	0.10
Athwardship offset	-0.06

**Transceiver 3 menu**

Transducer depth	5.5 m
Absorption coeff.	3 dB/km
Pulse length	short (0.7ms)
Bandwidth	wide
Max power	2000 Watt
2-way beam angle	-17.2 dB
SV transducer gain	23.87dB
TS transducer gain	23.82B
Angle sensitivity	13.9
3 dB beamwidth along.	10.9
3 dB beamwidth athw.	10.7
Alongship offset	0.04
Athwardship offset	0.09

**Transceiver 4 menu (default settings used)**

Transducer depth	5.5 m
Absorption coeff.	53 dB/km
Pulse length	Long
Bandwidth	Narrow
Max power	1000 Watt
2-way beam angle	-20.5 dB
SV transducer gain	23.84 dB
TS transducer gain	24.8 dB
Angle sensitivity	0.0
3 dB beamwidth along.	0.0°
3 dB beamwidth athw.	0.0°
Alongship offset	0.00°
Athwardship offset	0.00°

**Display menu**

Echogram	1
Bottom range	15 m
Bottom range start	10 m
TVG	20 log R
Sv colour min -	67 dB
TS Colour minimum	-50 dB

**Printer- menu**

TVG	20 log R
Sv colour min	-63 dB

**Bottom detection menu**

Minimum level	-50 dB
---------------	--------

## Calibration

A calibration of the acoustic equipment was conducted during the acoustic survey of the small pelagic resources off Angola in August 2005.

## Fishing gear

The vessel has three different sized four-panel 'Åkrahamn' pelagic trawls and one 'Gisund super bottom trawl'. The two smallest pelagic trawls and the demersal trawl were used during the survey. The smallest pelagic trawl has 10-12 m vertical opening under normal operation, whereas the intermediate sized trawl has 15-18 m opening.

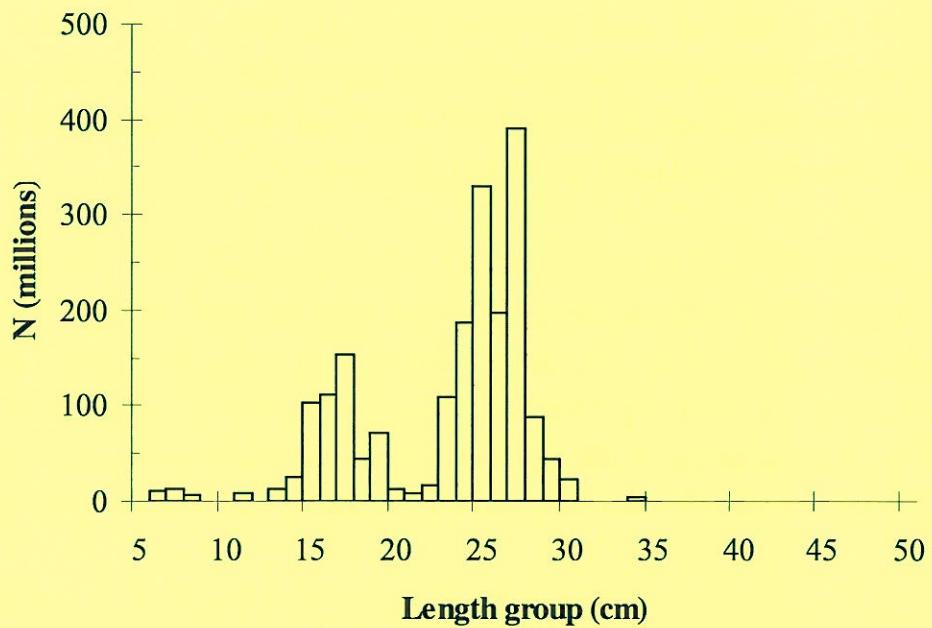

The bottom trawl has a 31 m headline and a 47 m footrope fitted with a 12" rubber bobbins gear. The codend has 20 mm meshes, and has an inner net with 10 mm mesh size. The vertical opening is about 5.5 m. The distance between the wing tips is about 18 m during towing. The sweeps are 40 m long. The trawl doors are 'Thyborøen' combi, 8 m<sup>2</sup> and weigh 2000 kg. The door spreading is about 45 m when using restraining rope. Trawling was conducted for species identification only and no restraining rope was therefore used during the survey.

The SCANMAR system was used during all trawl hauls. This equipment consists of sensors, a hydrophone, a receiver, a display unit and a battery charger. Communication between sensors and ship is based on acoustic transmission. The doors are fitted with sensors to provide information on their distance and a height sensor is fitted on the bottom trawl to measure the trawl opening and provide information on clearance and bottom contact.

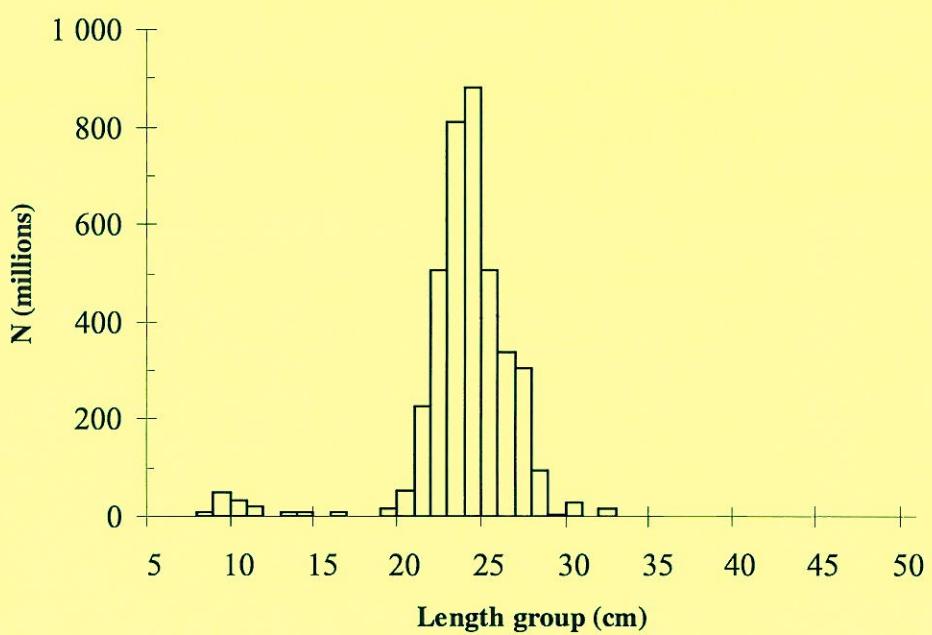

The pelagic trawls are equipped with a trawl eye that provides information about the trawl opening and the distance of the footrope to the bottom. A pressure sensor is used to show the depth on the headline.

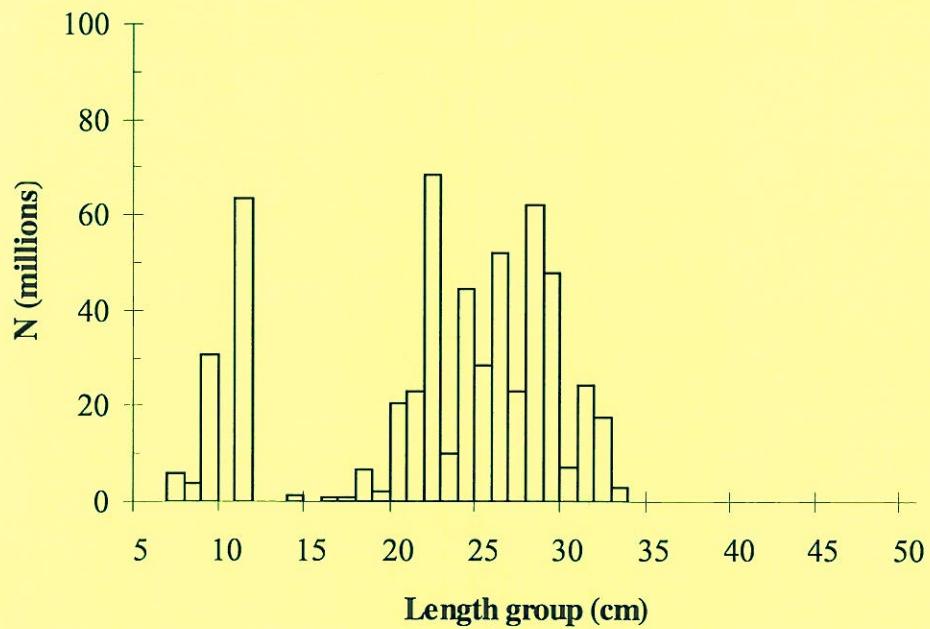

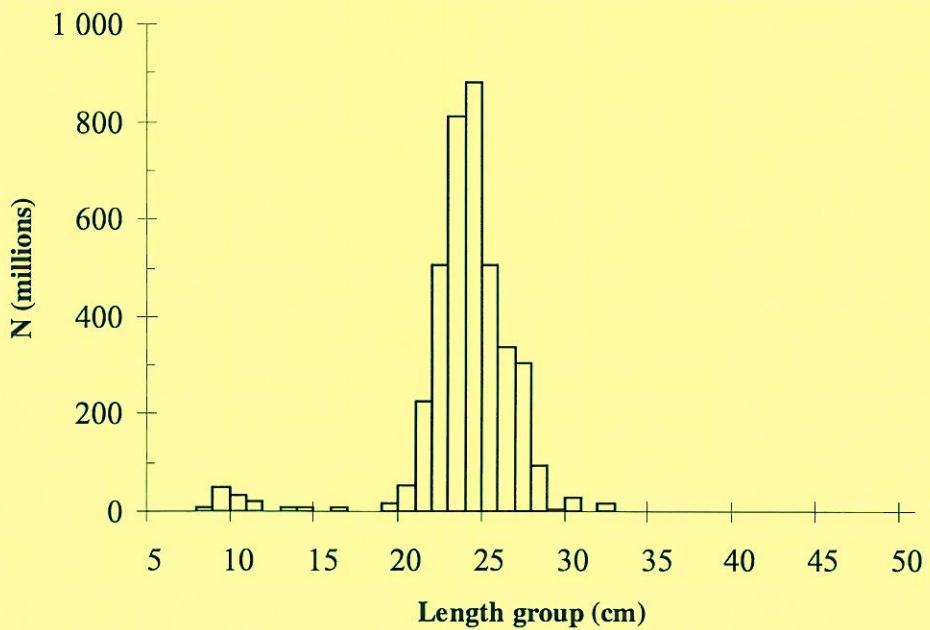

### Annex III Pooled length distributions by species

*Sardinella aurita* October – November 2005

*Sardinella maderensis* October – November 2005

*Trachurus trecae* October – November 2005*Decapterus rhothuchus* October – November 2005

## CHAPTER 1 INTRODUCTION

---

### 1.1 Objective of the cruise

The general objectives of the survey were to estimate biomass and map the distribution of the small pelagic fish stocks off NW Africa (Morocco, Mauritania, Senegal and the Gambia) by hydro-acoustic methods and describe the hydrographic conditions there over a period of 50 days, in November-December 2003. For Mauritania the agreed objectives were as follows:

- To map the distribution and estimate the biomass for the main small pelagic fish using hydro-acoustic methods. The species of interest were: sardinellas (*Sardinella aurita*) and (*Sardinella maderensis*), sardine (*Sardina pilchardus*) horse mackerels (*Trachurus trachurus*) and (*T. trecae*), false scad (*Decapterus rhonchus*), and anchovy (*Engraulis encrasicolus*) and chub mackerel (*Scomber japonicus*).
- To identify and describe the size distribution of the target fish populations by midwater and bottom trawl sampling and process the catches by recording weight and number by species.
- Collect biological data and otoliths of the main target species, especially *sardina pilchardus*, *Sardinella aurita*, *Sardinella maderensis* and *T. trecae*.
- To sample standard hydrographical transects for temperature, salinity and oxygen at every degree latitude, at about 17°00'N, 18°00'N, 19°00'N, 20°00'N and off Cape Blanc.
- To train local participants in acoustic survey methodology including fish identification and sampling, scrutinizing of echograms, acoustic abundance estimation and hydrographic sampling.
- To conduct a parallel survey with the Mauritanian research vessel Al Awam. This will include intercalibration and parallel trawling.

The time allocated for this part of the survey, off Mauritania, was 9 days.

## 1.2 Participation

Participating scientists were:

Institut Mauritanien de Recherches Océanographiques et des Pêches (IMROP), Mauritania:

Mamadou Sall Diallo, Abdoulaye Wagué (Team leader) , Jemal Ould Abed, Ibra Diallo

Centre de Recherches Océanographiques de Dakar-Thiaroye (CRODT), Senegal:

Abdoulaye Sarre

Department of Fisheries (FD), The Gambia:

Julda Jallow

Institut National de Recherche Halieutique (INRH), Morocco:

Salaheddine Al Ayoubi

Institute of Marine Research (IMR), Norway:

Jens-Otto Krakstad (Cruise leader), Magne Olsen, Tore Mørk and Jan Frode Wilhelmsen

## 1.3 Narrative

The vessel departed from Dakar 18:00 GMT on the 03<sup>rd</sup> November and steamed north to start the survey at the border between Senegal and Mauritania at St. Louis (16°00'N). The survey started off St. Louis at 07:00 GMT the next day together with the local Mauritanian R.V. "Al Awam". Both vessels followed the standardized survey outline used in Mauritania with systematic parallel course tracks spaced about 10 NM (nautical miles) apart, perpendicular to the depth isobaths. To cover the whole distribution area of pelagic fish, the shelf was covered from the 15 m isobath and offshore to the 500 m isobath. Trawling was done irregularly, either to identify echo registrations or to check 'blindly' if fish were mixed with the plankton in the upper layers of the water column. Pelagic trawl with floats was often used to catch fish close to the surface. A smaller pelagic trawl or the bottom trawl with floats was used for sampling pelagic fish in very shallow waters (depth less than 25 m).

The shelf and slope was covered from St. Louis at the border between Senegal and Mauritania to Cape Blanc. The vessel reached Cape Blanc and the end of the regular survey 11<sup>th</sup> November 18:30 GMT. The vessel then steamed to Nouakchott where the survey was completed on the 13<sup>th</sup> November at 17:00 GMT.

Course track and fishing stations are shown in Figure 1, while Table 1 show survey effort during the survey, including number of trawl stations and CTD casts. All data collected during the survey were made available to the participants.

Five transects with hydrographic profiles were carried out, at 17°00' N, 18°00'N - at Nouakchott, 19°00' - south of Cape Timiris, 20°00'N outside Banc D'arguin, and at 20°50' N - Cape Blanc.

Table 1. Summary of survey effort by regions, including number of demersal (BT) and pelagic (PT) trawl hauls, CTD casts, and distance surveyed (log), disregarding the steaming from Cape Vert to St. Louis and from Cape Blanc to Nouakchott (log).

Area	BT	PT	Total trawls	CTD casts	Log (nm)
St. Louis to Cape Blanc	14	22	36	57	1386

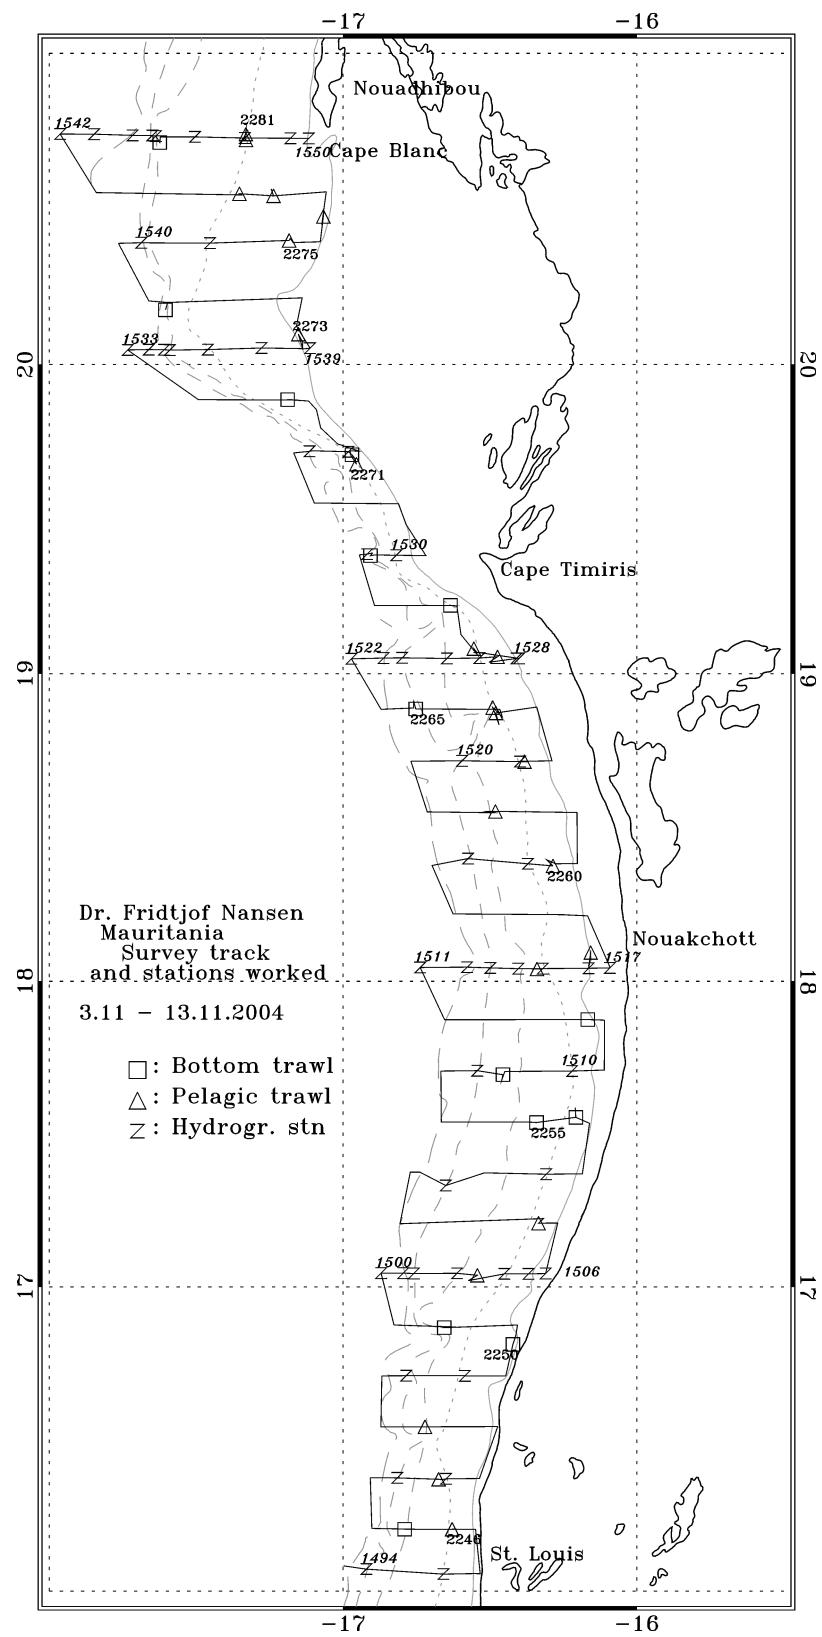

Figure 1. Course tracks with fishing and hydrographic stations; St. Louis to Cape Blanc

## CHAPTER 2 METHODS

---

### 2.1 Environmental Data

A Seabird 911+ CTD probe was used to obtain vertical profiles of the temperature, salinity and oxygen. Real time logging was carried out using the PC based Seabird Seasave software. CTD casts were conducted along the cruise track in transects at about every one degree latitude at 15 m - 20 m, 50 m, 100 m, 200 m, 500 m, 750 m and 1000 m bottom depth, and at fixed stations every 50 m and 200 m depth every 20 NM. The casts were stopped a few meters above the bottom, and at a maximum of 500 m depth. Two water samples, one near the surface and the other near the bottom, were collected using *Niskin* bottles at stations corresponding to the standard profiles. The samples were analysed for dissolved oxygen using the Winkler method in order to calibrate the oxygen sensor. Salinity of water samples was used to calibrate the salinity sensor using the Guildline Portasal salinometer. The salinity sensor on the CTD was stable and it was not necessary to apply any correction factor.

A total of 22 samples were accepted for oxygen calibration on 26<sup>th</sup> October 2004. A linear regression of the Winkler determinations on the CTD values produced the correction:

$$O_2\text{corrected} = a \cdot O_2\text{recorded} + b \quad (1)$$

were a=1.2498 and b=-0.0622

Sea surface salinity and relative temperature was continuously measured using a SBE 21 Seacat Thermosalinograph.

Meteorological data logged from the Aanderaa meteorological station included wind direction and speed, air temperature, incident solar intensity and sea surface temperature (SST). All data were averaged by unit distance sailed (1 NM).

### 2.2 Biological sampling

Biological sampling of the fish was carried out using trawls. A pelagic trawl with floats was often used. A smaller pelagic trawl or the bottom trawl with floats was used for sampling the pelagic fish in very shallow waters (depth less than 25 m). Annex II gives a description of the

instruments and the fishing gear used. All catches were sampled for composition by weight and numbers of each species caught. Species identification was based on the FAO Species Guides. Length frequency distributions, by total fish length in cm, of the selected target species were taken in all the stations where they were present. Individual weight measurements were taken regularly to estimate the condition factor in the length-weight relationship:

$$\bar{w} = \frac{cond}{100} \cdot L^3$$

The specific condition factors obtained from the samples and applied for this survey were: 0.96 for sardinellas and horse mackerels.

For the estimation of the biomass of carangids and associated species, an overall average length of 23 cm and a condition factor of 0.88 (to calculate the mean length of this length group) were applied. The target groups used for Mauritania can be found in Table 2, while the complete records of fishing stations and catches are shown in Annex I.

Table 2. Allocation of acoustic densities to taxii. Note that for the groups of sardinella, horse mackerel, and pilchard all encountered species are listed, while only examples are listed for the remaining groups.

<b>Group</b>	<b>TAXON</b>	<b>Species</b>
Sardinella	<i>Sardinella</i> sp.	<i>S. aurita</i> <i>S. maderensis</i>

<sub>1</sub>: other than *Sardinops* sp.; <sub>2</sub>: other than *Trachurus* sp.; <sub>3</sub>: main taxon in group.

### 2.3 Acoustic sampling

A SIMRAD EK500 Echosounder was used with the settings as shown in Annex II. All four frequencies 18 kHz, 38 kHz, 120 kHz and 200 kHz were logged. All abundance estimation was based on data from the 38 kHz transducer. The Bergen Integrator (BEI) was used for analysis and allocation of the integrated  $s_A$ -values to the individual specified target groups by 5 NM intervals. The allocation of values to target groups was based on a combination of a visual scrutiny of the behaviour pattern as deduced from echo diagrams, the BEI analysis, and the catch compositions.

In cases where the target category of fish contains more than one species (sardinellas and horse mackerels), the mean  $s_A$ -value allocated to the category is divided between the species in the same ratio as their contribution to the mean back scattering strength in the length frequency samples.

The following target strength (TS) function was applied to convert  $s_A$ -values (mean integrator value for a given species or group of species in a specified area) to number of fish:

$$TS = 20 \log L - 72 \text{ dB}$$

Which can be converted (see Toresen *et al.* 1998 for details) to the area form (scattering cross sections of acoustic targets):

$$C_{Fi} = 1.26 \cdot 10^6 L^{-2}$$

where  $L$  is total length in 1 cm length group  $i$  and  $C_{Fi}$  ( $\text{m}^{-2}$ ) is the reciprocal back scattering strength, or so-called fish conversion factor. In order to split and convert the allocated  $s_A$ -values ( $\text{m}^2/\text{NM}^2$ ) to fish densities (numbers per length group per  $\text{NM}^2$ ), the following formula was used:

$$\rho_i = s_A \cdot \frac{p_i}{\sum_{i=1}^n \frac{p_i}{C_{Fi}}}$$

were

$\rho_i$  = density of fish in length group  $i$

$s_A$  = mean integrator value

$p_i$  = proportion of fish in length group  $i$

$\sum_{i=1}^n \frac{p_i}{C_{Fi}}$  = the relative back scattering cross section ( $\text{m}^2$ ) of the length frequency sample of the target species, and

$C_{fi}$  = reciprocal back scattering cross section ( $\sigma_{bs}^{-1}$ ) of a fish in length group  $i$ .

The integrator outputs were split in fish groups using a combination of behaviour pattern as deduced from echo diagrams, the BEI analysis and catch composition as described below. The following groups were used for Senegal: 1) sardinellas, 2) horse mackerels, 3) carangids and associated species, and 4) demersal fish.

The above equations show that the conversion from  $s_A$ -values to number of fish is dependent on the length composition of the fish. It is therefore important to get representative length distributions from the stock in the whole distribution area.

When the size classes (of e.g. young fish and older fish) are well mixed, the various length distributions can be pooled together with equal importance. Otherwise, when the size classes are segregated, the total distribution area has to be post-stratified, according to the length distributions, and separate estimates are made for the regions containing fish with equal size.

For a region representing a distribution of a target-specie, the following basic data are needed for the estimation of abundance;

- 1) the average  $s_A$ -value for the region,
- 2) the surface (usually square nautical miles,  $NM^2$ ), and
- 3) a representative length distribution of the fish in the region.

If the targeted fish is a mixture of more than one species, for example sardinellas, a representative distribution of the two, within the region, as shown in the trawl catches, are used. A length distribution representing the number of the two species for each catch will have to be calculated. Thereafter, these distributions have to be normalized to a unit number (usually 100) so they are equally weighted.

A systematic approach to a) divide the  $s_A$ -value between species in a category of fish (e.g. *Sardinella aurita* and *S. maderensis*), b) produce pooled length distributions of a target species for use in the above equation and c) calculate the biomass estimates for a region, is obtained through the following procedure:

The samples of the species in the category (e.g. sardinellas) are respectively pooled together with equal importance (normalized).

The mean back scattering strength ( $\rho/s_A$ ) of each length frequency distribution of the target species is calculated and summed. This is automatically done in the Excel spread-sheet made available for acoustic abundance estimation onboard RV "Dr. Fridtjof Nansen", provided the data are punched in this sheet.

The mean  $s_A$ -value allocated to the category of fish in the region is divided between the species in the same ratio as their relative contribution to the mean back scattering strength of the length groups in the sample representing the region

The pooled length distribution is used, together with the mean  $s_A$ -value, to calculate the density (numbers per square NM) by length groups and species, using the above formula. The total number by length group in the area is obtained by multiplying each number by the area. The numbers are then converted to biomass using the estimated weight at length.

#### **2.4 Parallel survey with R.V. “Al Awam”**

During the survey the Mauritanian research vessel “Al Awam” did a parallel survey with “Dr. Fridtjof Nansen”. As part of this, parallel trawl hauls were conducted with regular intervals, as well as acoustic intercalibration between the vessels. The strategy for the intercalibration followed the recommendations by MacLennan and Simmons (1992).

One of the research vessels placed itself 0.5 NM behind and 0.5 NM to the side of the vessel that took the lead. The distance between the vessels were chosen so that the vessels could stay as close together as possible without disturbing each other’s acoustic recordings. Starting time and log were recorded onboard each vessel and the distance between vessels was kept constant during the experiment.

All data collected during the parallel survey and intercalibration will be analysed on land and a separate report will be produced on the exercise.

## CHAPTER 3 SURVEY RESULTS

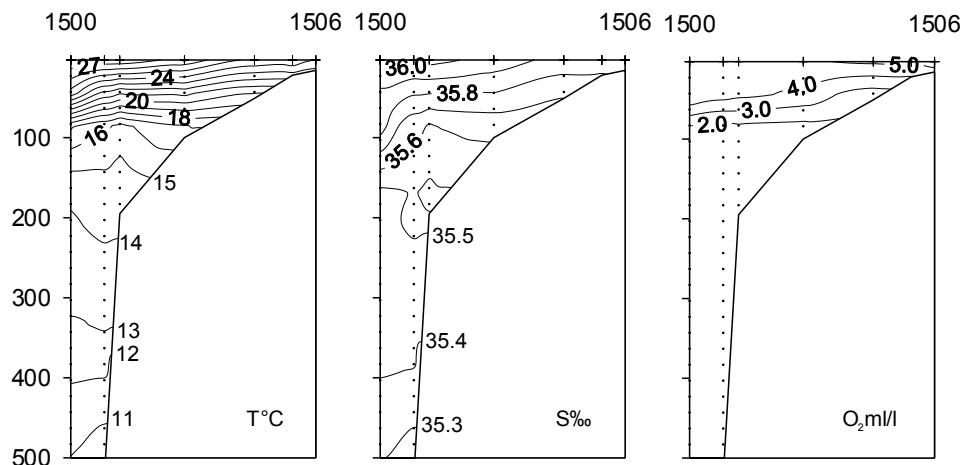

---

### 3.1 Hydrography

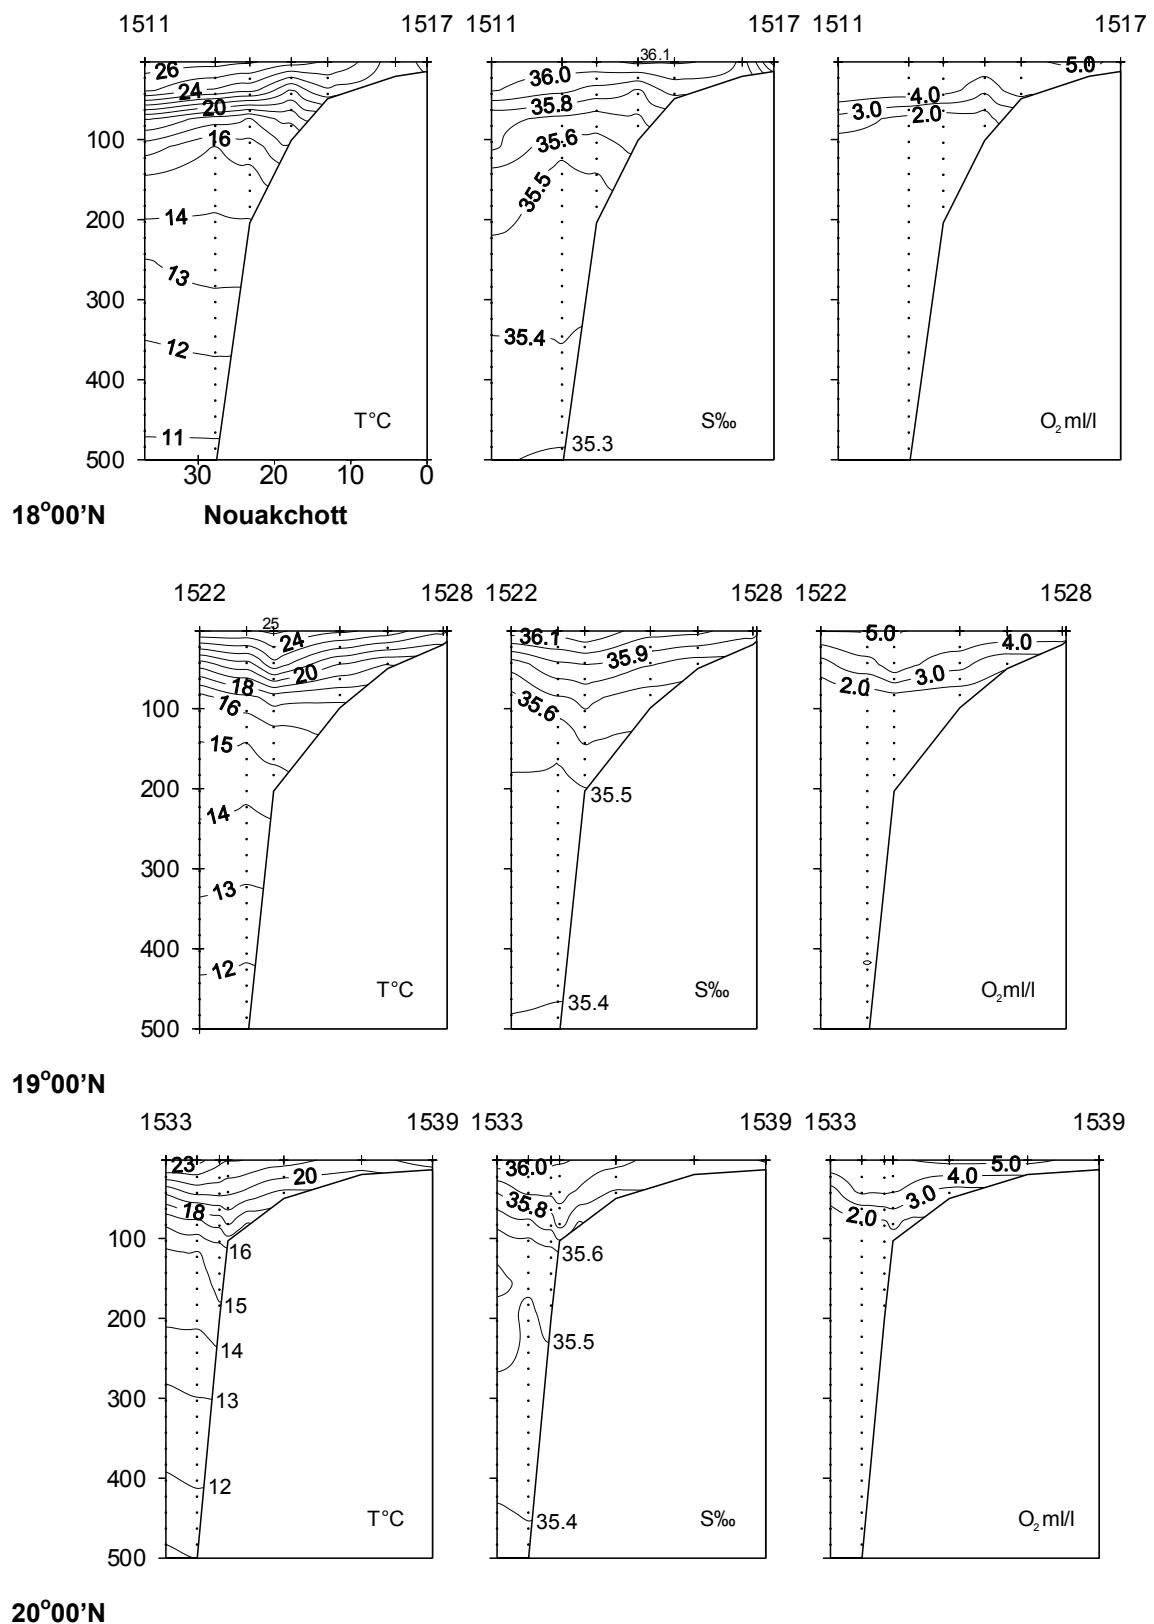

Hydrographical data was collected on fixed CTD stations to 500 m depth and from the Aanderaa weather station that continuously collect sea surface temperature, wind speed and direction, solar radiation etc. during the survey.

#### *Cross shelf hydrographical profiles*

Figure 2 shows the distribution of temperature, salinity and oxygen from the five hydrographical transects collected during the survey. Typically, the surface waters showed an increase in water temperature from the coast and offshore. A gradual decrease in water temperature characterises the upper 80 m of the water column. The decrease in water temperature was less rapid below this, with the lowest temperatures found along the bottom, temperatures around 11°C measured at 500 m depth. No typical thermocline was present along the hydrographical transects. The water masses became colder and more mixed with a less defined thermocline northwards along the Mauritanian coast, with a surface temperature of 23°C offshore at Cape Blanc. The surface waters show relatively high salinity, around 36 ‰ in the offshore waters, with decreasing salinity towards the coast. More turbulent water masses are present in the northern part of the region around Cape Blanc. All the CTD transects show well oxygenated waters, with approximately 5 ml/l O<sub>2</sub> in the surface water, declining to 2 ml/l O<sub>2</sub> at approximately 70 m depth.

17°00'N

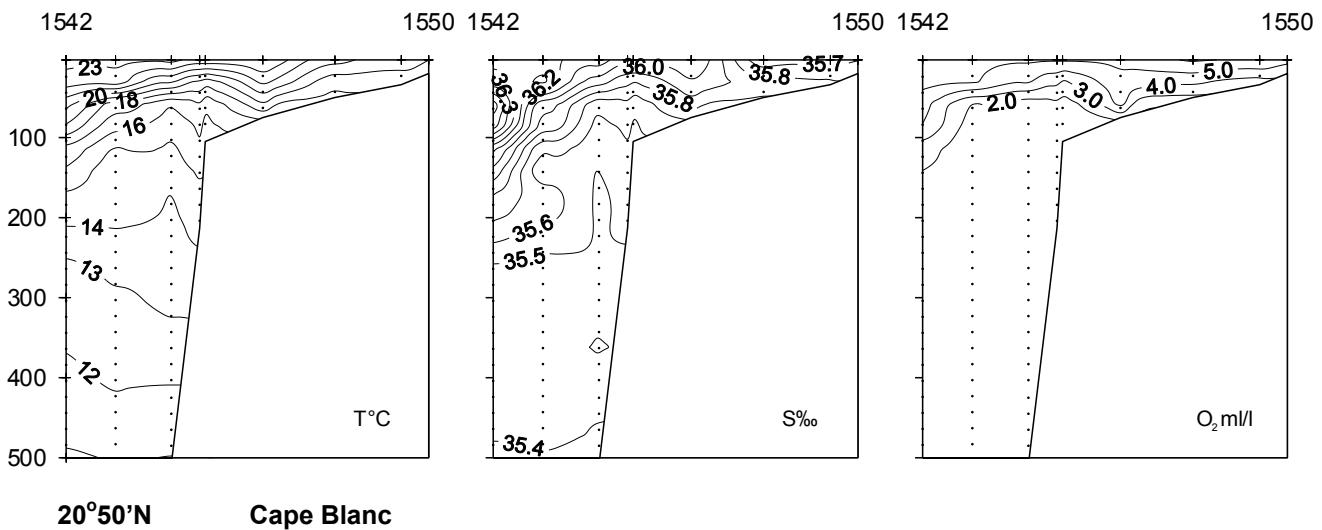

Figure 2. Hydrographical profiles with distribution of temperature, salinity and oxygen

#### *Sea surface temperature and wind direction*

Figure 3 shows the sea surface temperature at 5 m of depth while Figure 4 shows the sea surface salinity at 5 m depth. The southern part of Mauritania was characterized by relatively warm waters. The temperature isobaths were directed alongshore, with the coolest waters inshore and increasingly warmer temperature offshore, with a maximum of more than 27°C. North of Nouakchott temperature isobaths were running across shelf and a frontal zone is visible. However the waters are more turbulent again at Cape Timiris and warmer offshore water masses were brought into the shelf. In the north of the survey area a body of colder waters as low as 20°C was intruding into the Mauritanian shelf. And temperatures dropped with up to three degrees in less than 50 m surface distance at the border between the cold costal waters and offshore water masses. Water masses in the whole survey area were generally much warmer than last year, and cold water masses (20°C) were only present in the northern part of the survey area.

The sea surface salinity supports the picture seen from the sea surface temperature. Little variability in sea surface salinity is seen in the south of Cape Timiris and the salinity was stable around 35.9‰. North of this a body of less saline waters are seen at Cape Blanc with salinity around 35.5‰ corresponding with the cold water masses from the Canary current coming from north of the survey area.

Figure 5 show the wind direction and wind speed during the survey of Mauritania. The wind came from north and northwest in the southern part of the survey area. North of Nouakchott and around Cape Timiris more variable winds were experienced, with the wind direction often coming from northeast turning to southeast. Wind direction should be favourable for

upwelling in this area. At Cape Blanc the wind was stable from a northerly direction. The conditions were favourable for acoustic surveying throughout the survey.

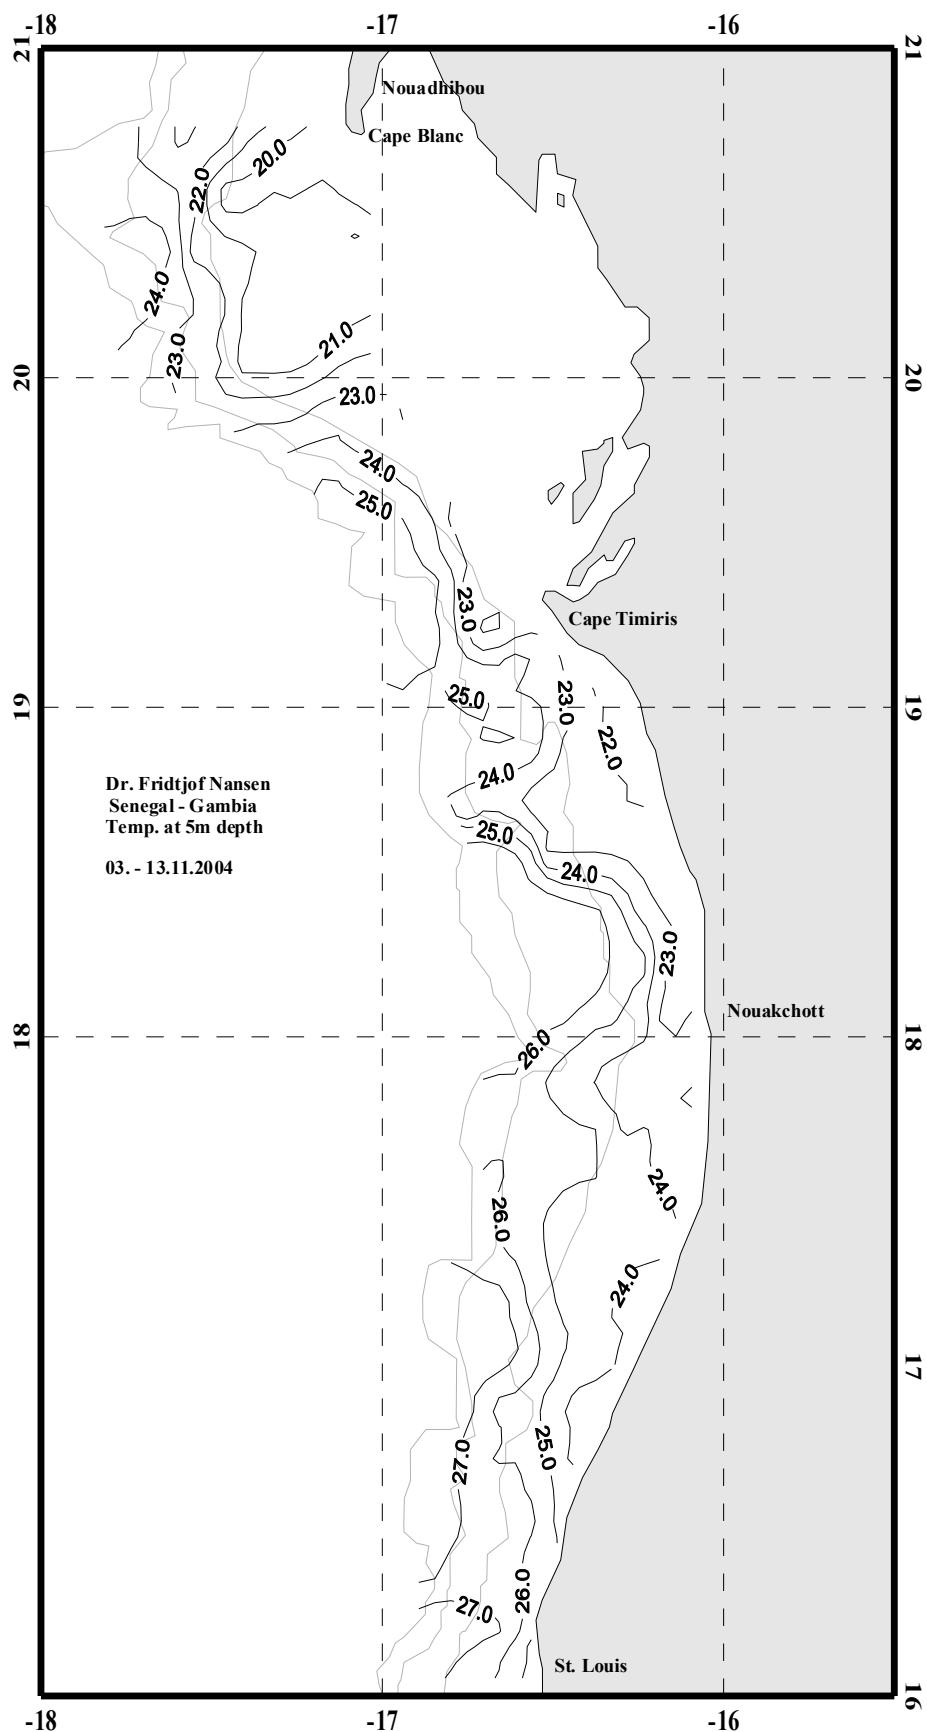

Figure 3. Sea surface temperature; St. Louis to Cape Blanc

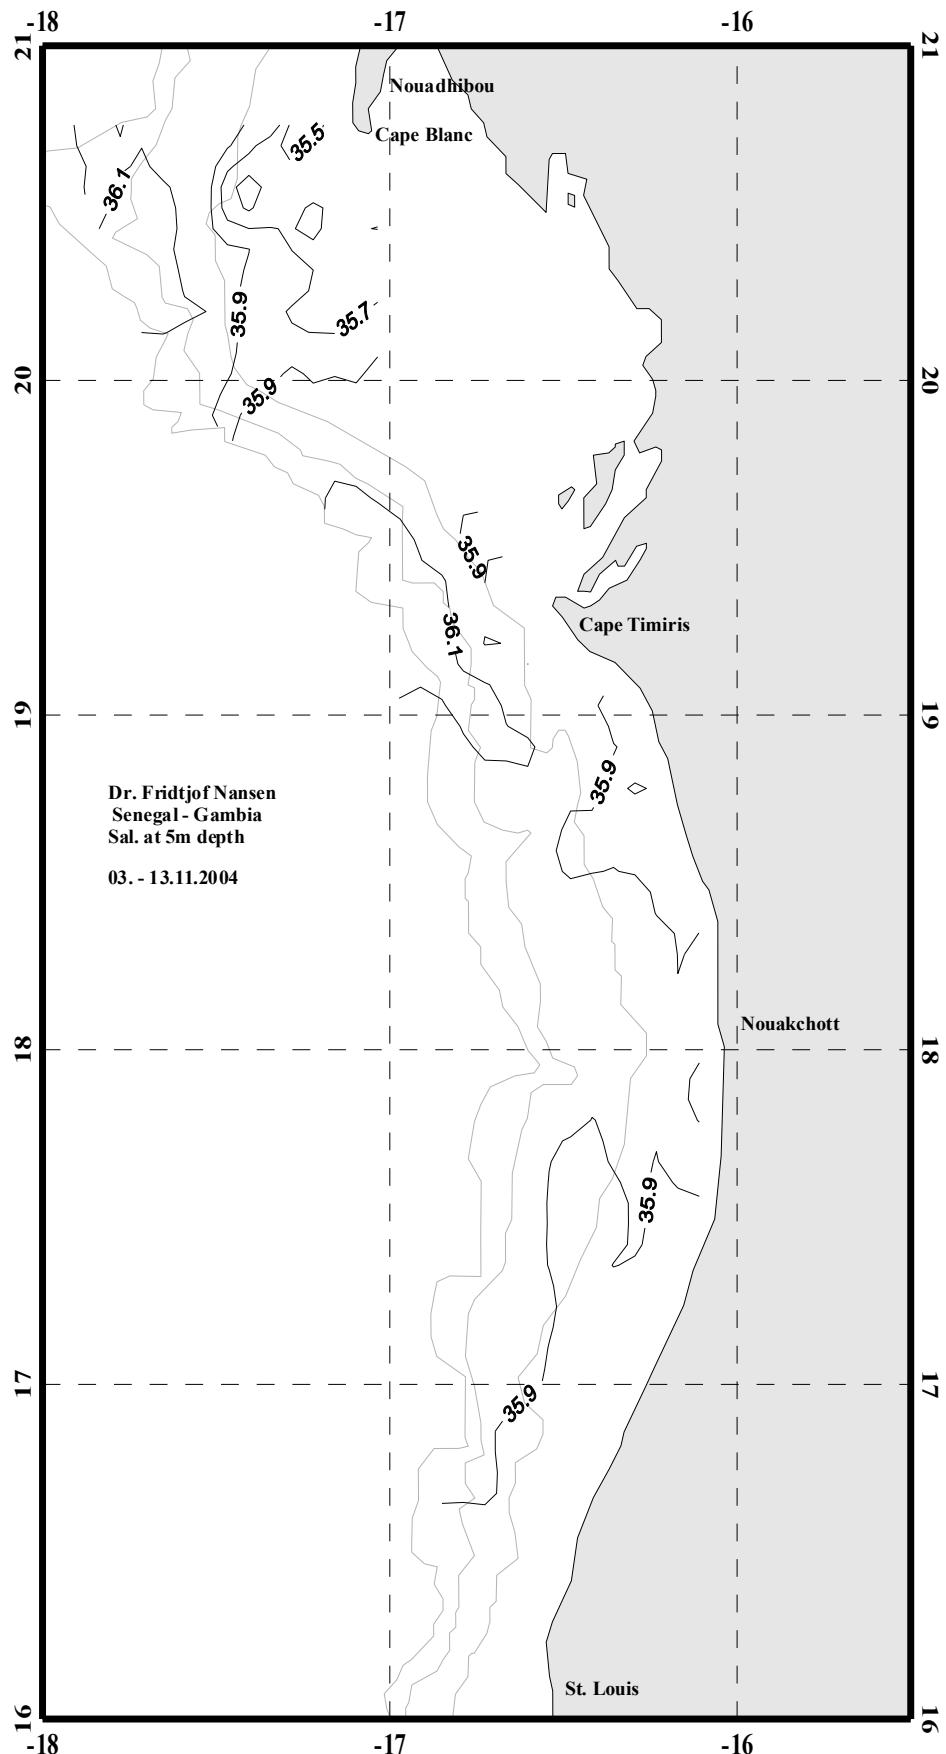

Figure 4. Sea surface salinity; St. Louis to Cape Blanc

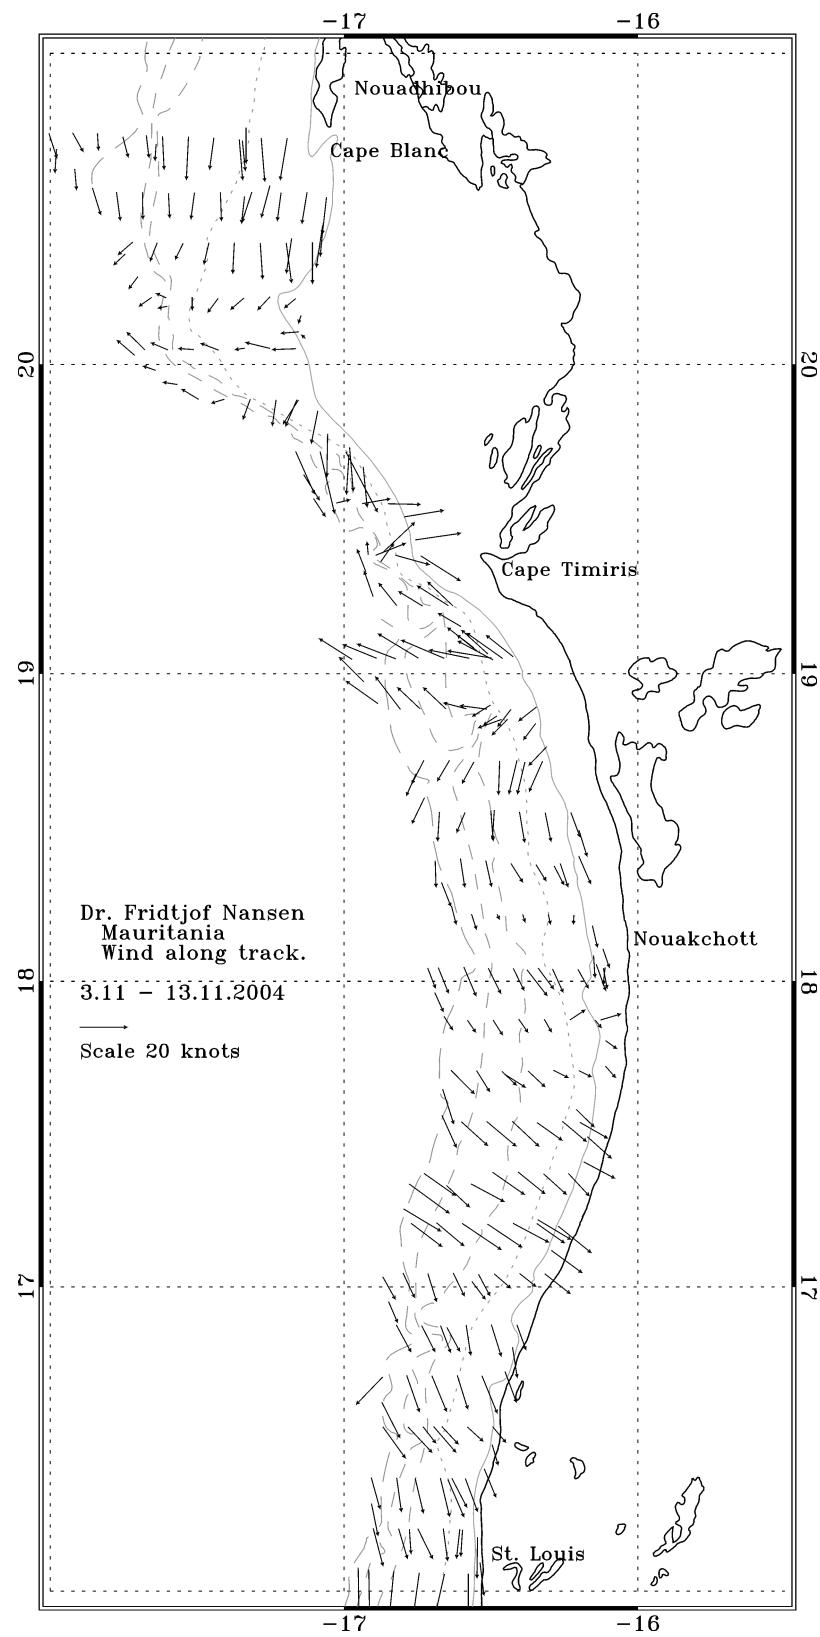

Figure 5. Wind speed and direction; St. Louis to Cape Blanc

### 3.2 St. Louis to Cape Timiris

The main groups of pelagic fish for the shelf of Mauritania illustrated with contoured acoustic densities are seen in Figure 6, Figure 7, Figure 8 and Figure 9.

*Sardinella* was found in two large distribution areas on the shelf between St. Louis and Cape Timiris, extending northwards into Banc D'arguin. The density was variable within each of the two main distribution areas, mainly with high to medium densities, and with low densities at the edge between the two main distribution areas. The sardinella was mainly distributed between the 15 m depth and offshore to more than 50 m depth, with highest concentrations found around 20–30 m depth, Figure 6. Both species of sardinella were found in the area. The biomass of *S. aurita* was estimated to be 189 thousand tons, while the biomass of *S. maderensis* was estimated at 1 244 thousand tons.

Three modal peaks at 14 cm, 28 cm and 33 cm total length was observed for *Sardinella maderensis*, and more than 99% of the biomass was >20 cm. The modal size groups of *S. aurita* were 17 cm, 26 cm and 29 cm. Estimated number and biomass by length-groups are in Annex IV. The total biomass of sardinellas in the area was estimated at 1433 thousand tonnes, Table 3.

*Trachurus trecae* were found in five low-density areas between St. Louis and Cape Timiris, mainly between 50 m and 200 m depth. The highest concentrations were generally found at the shelf break close to the bottom, Figure 7. Horse mackerel was also occasionally found dispersed further inshore, mainly mixed with plankton and other pelagic species. A few catches of *Trachurus trachurus* were made offshore south of Cape Timiris. The biomass of *Trachurus trecae* in the area was estimated to be 29 thousand tons, while 0.8 thousand tons of *Trachurus trachurus* were found. No separate estimate of *Decapterus rhonchus* was made. The *Trachurus trecae* showed two modal peaks, at 13 cm and 23 cm roughly corresponding to one and three year old fish.

One catch of sardine (*Sardina pilchardus*) were made in shallow waters south of Cape Timiris. The modal length of the sardine in the catch was 25 cm. A few schools were found concentrated in this area, and the abundance was estimated to be 20 thousand tonnes.

Anchovy (*Engraulis encrasicolus*) were not found south of Cape Timiris

Other pelagic fish were found in low concentrations over large parts of the shelf. The main concentrations were between 50 and 20 m bottom depth, Figure 9. The P2's were rarely

distributed further offshore than the 100 m isobath. In general both carangids other than horse mackerel, scombrids, hairtails and barracudas were found in the area, Table 4. The catches were dominated by *Decapterus rhonchus*, *Trichiurus lepturus*, *Brachydeuterus auritus*, and *Selene dorsalis*. The species were well mixed with the sardinellas and horse mackerel in the areas where their distribution overlapped. The estimated biomass of this group of fish was 106 thousand tonnes. This includes *Decapterus rhonchus* which often has been estimated separately. However it was not possible this year to distinguish this species from the rest of the Carangid species in the region.

### 3.3 Cape Timeris – Cape Blanc

Both species of sardinellas were found on the shelf at Cape Blanc from less than 20 m depth to the 50 m isobath, Figure 6. The highest concentrations were found in the northernmost part of the area and inshore, and some sardinella was probably missed in the shallow part (<15 depth) of Banc D'arguin. The total estimate of sardinellas between Cape Timiris and Cape Blanc during this survey was 115 thousand tons, Table 5. This comprised of 91 thousand tons of *S. maderensis* and 24 thousand tons of *S. aurita*. Similar to last year, mainly adults of *S. maderensis* were found in the area, with one modal peak visible at 22 cm. The *S. aurita* in the area showed two modal peaks at 8 cm and 23 cm. The estimated number and biomass by length-groups are in Annex IV.

Sardine (*Sardina pilchardus*) was found in high- very high concentrations south of Cape Blanc, extending northwards. Highest concentrations were found around 50 m depth, Figure 8. The biomass of sardine in this area was estimated to be 384 thousand tons, Table 5. This consisted of one cohort with adult fish, with a modal peak at 25 cm.

Anchovy (*Engraulis encrasicolus*) were found in two trawl samples at night south of Cape Blanc in shallow waters, <50 m depth. No attempt was made to estimate the biomass.

Cunene and Atlantic horse mackerel was found mixed in one area from Cape Blanc and southwards on the shelf and shelf break to Cape Timiris around 100 m depth, while another area inshore off Cape Blanc consisted of Cunene horse mackerel only, Figure 7. *Decapterus rhonchus* was found further north than usual due to the warmer than normal water conditions. The species was thoroughly mixed with other pelagic species, hence no separate estimate was made and the biomass included as part of the P2. The estimated biomass of horse mackerels in the area were 53 thousand tons, Table 5. The biomass estimate comprised of 45 thousand tons of *Trachurus trecae* and eight thousand tons of *T. trachurus*. The biomass of *T. trecae* consisted mainly of juveniles, with a modal peak of 12 cm, while *T. trachurus* in the area showed a modal peak at 26 cm. Some few adult *T. trecae* with a modal peak around 41 cm was also found on the shelf break. The estimated number and biomass by length-groups can be found in Annex IV.

Carangids and associated species were found in low density across the shelf in the whole area between Cape Timiris and Cape Blanc, Figure 9. Hairtails, *Trichiurus lepturus*, dominated the group by weight, but *Decapterus rhonchus* and *Chloroscombrus chrysurus* were also frequent in the catches on the shelf. The biomass estimate of this group was 42 thousand tons, Table 5.

### 3.4 Parallel trawl survey

The parallel trawl survey was conducted successfully. During the survey of Mauritania the R.V. “Al Awam” followed the same course track as R.V. “Dr. Fridtjof Nansen”. As part of the parallel trawl survey several rounds of intercalibration were conducted successfully. The data from the parallel survey will be analysed later and presented in a separate report.

## CHAPTER 4 OVERVIEW AND SUMMARY OF RESULTS

---

The survey was conducted successfully from 3<sup>rd</sup> to 13<sup>th</sup> November, covering a course track of approximately 1 386 NM. A total of 36 fishing stations and 57 CTD casts were established.

The hydrographical data showed warmer than usual surface temperatures over most of the Mauritanian shelf. Cold water (20°C) was only present in the northernmost part of the survey area around Cape Blanc, Figure 3. The southern part of Mauritania showed stable salinity levels around 35.9‰ while the cold water area around Cape Blanc had lower salinity levels around 35.5‰. The shelf was well oxygenated in the whole survey area.

Sardinellas were generally found along the whole shelf of Mauritania, between 15 m depth and offshore to approximately 50 m bottom depth, Figure 6. Similar to last year in November the bulk of the biomass was dominated by *S. maderensis* (86%). The majority of the biomass of both species was found south of Cape Timiris. North of this, only 24 thousand and 91 thousand tons of *S. aurita* and *S. maderensis* respectively, were found, Table 7. However, division of biomass between the two species of sardinella relies entirely on trawl samples. Sardinella shows strong trawl avoidance and some care should therefore be taken when interpreting the results at species level. The concentration area of sardinella south of Cape Blanc was on the inner part of the shelf. It is probable that some sardinella was distributed on the large shelf area inside of 15 m bottom depth, and therefore not found during the survey.

Sardine were found inshore in shallow waters in a small area at Cape Timiris, and in a larger distribution around the border area at Cape Blanc, extending across the border and following roughly the same distribution as the cold water intrusion from the north. The total biomass in Mauritanian waters were estimated to be 405 thousand tons

Cunene horse mackerel were found in several low-density areas all along the coast of Mauritania. The main part of the distribution was between 50 and 100 m depth, but some Cunene horse mackerel was also found inshore of the 50 m isobath. Small concentrations of Atlantic horse mackerel started to mix with the Cunene horse mackerel, mainly on the outer part of the shelf and the shelf break in the northern part of Mauritania, Figure 7. The total abundance estimate of Cunene horse mackerel was 74 thousand tons while the estimate of Atlantic horse mackerel was 9 thousand tons.

Other carangids and associated species were distributed over most of the shelf at rather low densities along the whole coast, Figure 9. The main species in the catches was *Trichiurus lepturus*, hairtails, while *Decapterus rhonchus* and *Brachydeuterus auritus* was frequently caught on the shelf south of Cape Timiris and *Decapterus rhonchus* and *Chloroscombrus chrysurus* dominated north of cape Timiris. The main groups of species in the catches can be found in Table 4. The total biomass was estimated at approximately 69 thousand tons, of this 51 thousand tons were found south of Cape Timiris.

An overview of the acoustic estimates of biomass of the main groups of pelagic fish is shown in Table 7, and the geographical distribution and abundance of main species is in Figure 10. The total biomass of sardinellas was thus 1 548 thousand tons, horse mackerels 83 thousand tons and of carangids and associated species 148 thousand tons. Note that *Decapterus rhonchus* has been included in the biomass of other Carangids (P2) as no biomass estimate was made for this group.

Table 7. Summary of biomass estimates of pelagic fish, Mauritania. thousand tons.

	<i>Sardinella maderensis</i>	<i>Sardinella aurita</i>	<i>Sardina pilchardus</i>	Horse mackerels	Carangids etc.
St. Louis – Cape Timiris	1244	189	20	30	106
Cape Timiris – Cape Blanc	91	24	384	53	42
Total	1335	213	404	83	148

The abundance of sardinella in Mauritanian waters has increased immensely since the very low estimate in November 2002 were only 320 tons of sardinella were found. This year's estimate is the highest since November 1995. The large increase in the biomass of sardinella may also explain the decrease in the biomass of horse mackerels and some of the other carangid species. The abundance of Cunene horse mackerel in particular is lower than it has been in many years.

The total estimate of carangids and associated species (including horse mackerel) was estimated at 231 thousand tons. This is low compared to last years estimate. There seems to be a downward trend in the biomass estimates of these species, which may have connection with the large increase of sardinella species in the region.

### **Annex III Instruments and fishing gear used**

The Simrad EK-500, 38kHz scientific echosounder was used for abundance estimation during the survey, in addition data from the 18 kHz, 120 kHz and 200 kHz transducers were recorded for possible future multifrequency target identification. The Bergen Echo Integrator system (BEI) recorded the hydroacoustic data and was used to scrutinize the acoustic records, and to allocate integrator data to fish species. All raw data were stored to tape and brought back to IMR for storing.

The details of the settings of the echosounders were as follows:

#### **Transceiver 1 menu**

Transducer depth	5.5 m
Absorption coeff.	10 dB/km
Pulse length	medium (1ms)
Bandwidth	wide
Max power	2000 Watt
2-way beam angle	-21.0 dB
SV transducer gain	27.17dB
TS transducer gain	29.96
Angle sensitivity	21.9
3 dB beamwidth along.	7.3
3 dB beamwidth athw.	7.0
Alongship offset	0.05
Athwardship offset	0.04

#### **Transceiver 2 menu**

Transducer depth	5.5 m
Absorption coeff.	38 dB/km
Pulse length	long (1ms)
Bandwidth	narrow
Max power	1000 Watt
2-way beam angle	-20.6 dB
SV transducer gain	25.96B
TS transducer gain	25.95dB
Angle sensitivity	21.0
3 dB beamwidth along.	7.4
3 dB beamwidth athw.	7.2
Alongship offset	0.24
Athwardship offset	0.04

**Transceiver 3 menu**

Transducer depth	5.5 m
Absorption coeff.	3 dB/km
Pulse length	short (0.7ms)
Bandwidth	wide
Max power	2000 Watt
2-way beam angle	-17.2 dB
SV transducer gain	23.75dB
TS transducer gain	23.36B
Angle sensitivity	13.9
3 dB beamwidth along.	10.8
3 dB beamwidth athw.	10.8
Alongship offset	0.06
Athwardship offset	-004

**Transceiver 4 menu**

Transducer depth	5.5 m
Absorption coeff.	53 dB/km
Pulse length	Long
Bandwidth	Narrow
Max power	1000 Watt
2-way beam angle	-20.5 dB
SV transducer gain	24.18 dB
TS transducer gain	24.80 dB
Angle sensitivity	0.0
3 dB beamwidth along.	0.0°
3 dB beamwidth athw.	0.0°
Alongship offset	- 0.00°
Athwardship offset	0.00°

Minimum level	-40 dB
---------------	--------

**Calibration**

A calibration of the acoustic equipment was conducted during the survey in Angola in August 2004.

### **Fishing gear**

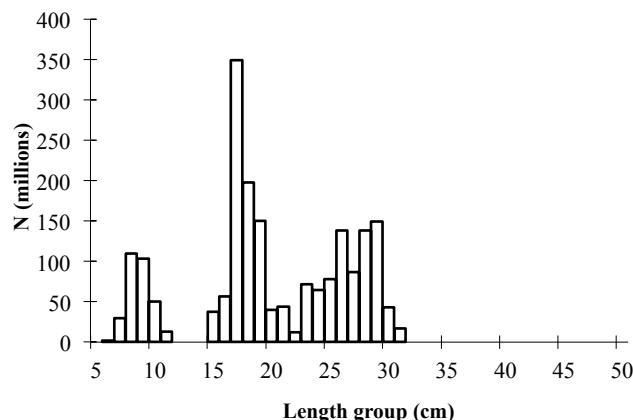

The vessel has three different sized four-panel 'Åkrahamn' pelagic trawls and one 'Gisund super bottom trawl'. The two smallest pelagic trawls and the demersal trawl were used during the survey. The smallest pelagic trawl has 10-12 m vertical opening under normal operation, whereas the intermediate sized trawl has 15-18 m opening.

The bottom trawl has a 31 m headline and a 47 m footrope fitted with a 12" rubber bobbins gear. The codend has 20 mm meshes, and has an inner net with 10 mm mesh size. The vertical opening is about 5.5 m. The distance between the wing tips is about 18 m during towing. The sweeps are 40 m long. The trawl doors are 'Thyborøen' combi, 8 m<sup>2</sup> and weigh 2000 kg. The door spreading is about 45 m when using restraining rope. Trawling was conducted for species identification only and no restraining rope was therefore used during the survey.

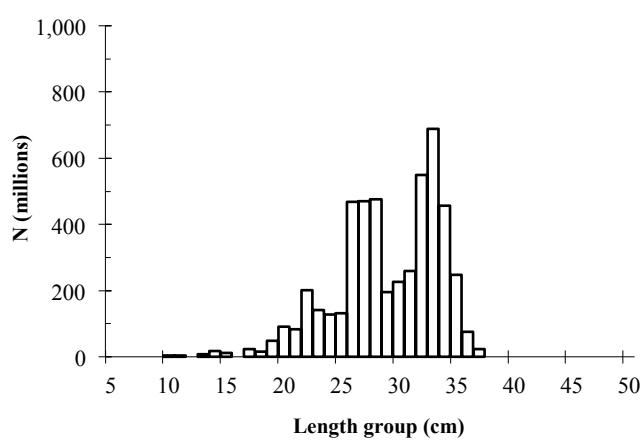

The SCANMAR system was used during all trawl hauls. This equipment consists of sensors, a hydrophone, a receiver, a display unit and a battery charger. Communication between sensors and ship is based on acoustic transmission. The doors are fitted with sensors to provide information on their distance and a height sensor is fitted on the bottom trawl to measure the trawl opening and provide information on clearance and bottom contact.

The pelagic trawls are equipped with a trawl eye that provides information about the trawl opening and the distance of the footrope to the bottom. A pressure sensor is used to show the depth on the headline.

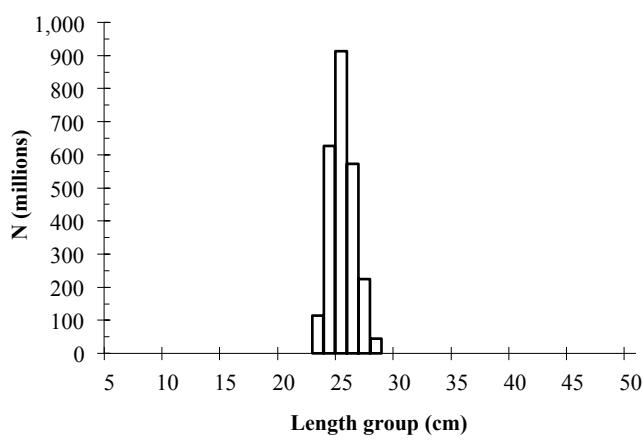

### Annex III. Pooled length distribution by species and region

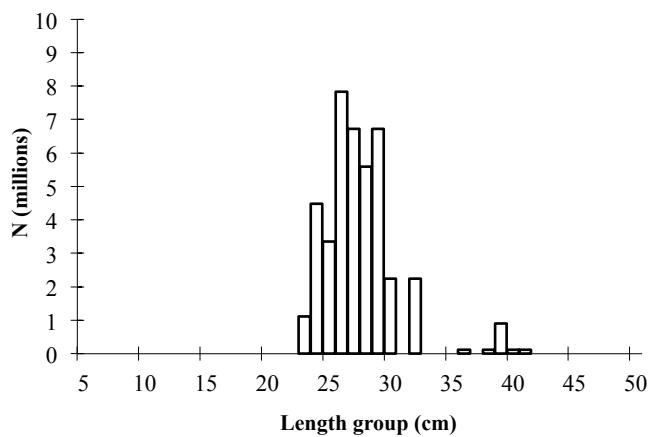

*S. aurita* (*Sardinella aurita*) November 2004

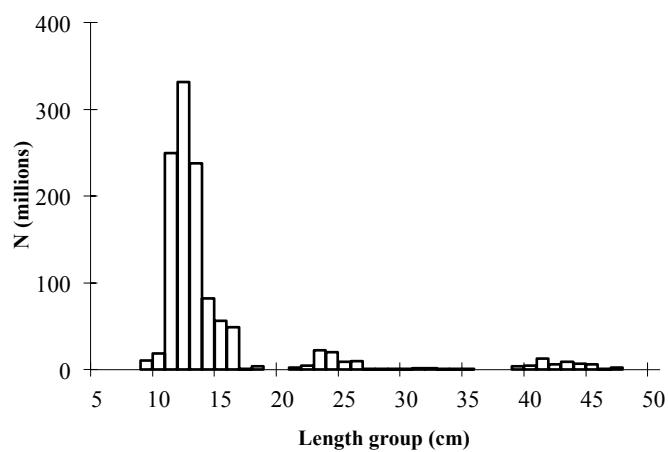

*S. maderensis* (*Sardinella maderensis*) November 2004

Sardine (*Sardina pilchardus*) November 2004

Atlantic horse mackerel (*Trachurus trachurus*) November 2004

Cunene horse mackerel (*Trachurus trecae*) November 2004

## CHAPTER 1 INTRODUCTION

---

### 1.1 Survey objectives

The specific objectives for the survey were, as for the previous surveys:

- To map the distribution and estimate the biomass of the main small pelagic fish species using hydroacoustic methods. The species of interest were: sardine *Sardina pilchardus*, sardinellas *Sardinella aurita*, *S. maderensis*, chub mackerel *Scomber japonicus*, horse mackerel *Trachurus trachurus*, *T. trecae*, and anchovy *Engraulis encrasicolus*.
- To identify acoustic targets by midwater and bottom trawl sampling and process the catches by recording weight and number by species. For the target species, length frequencies are taken to describe the size distribution.
- To collect otoliths of sardine and sardinella, and training in age determination.
- To sample standard hydrographical transects for temperature, salinity and oxygen off Cape Blanc, Dakhla, Cape Bojador, Cape Juby, Cape Dra and Cape Ghir.

In addition:

- To intercalibrate with RV *Al Amir Moulay Abdallah* between Cape Juby and Cape Cantin.

The time allocated for this part of the survey was 25 working days.

### 1.2 Participation

Members of the scientific teams were:

Institut National de Recherche Halieutique, Morocco:

Hammou EL HABOUZ (team leader), Lahcen ABOUABELLAH, Ahmed EL YOUSSEIFI, Salaheddine EL AYOUBI and Rachid ERROUAGUI.

Institut Mauritanien de Recherches Océanographiques et des Pêches (IMROP), Mauritania:  
Cheikh Tidjane DIOP.

Centre de Recherches Océanographiques de Dakar-Thiaroye (CRODT), Senegal:  
Abdoulaye SARRE.

From IEO, Tenerife, Spain:

Maria Teresa GARCIA SANTAMARIA (until 27 November).

Institute of Marine Research, Norway (IMR):

Oddgeir ALVHEIM (cruise leader), John DALEN (until 27 November), Thor Egil JOHANSSON (from 27 November), Tore MØRK, Marek OSTROWSKI and Jan Frode WILHELMSEN (until 27 November).

### 1.3 Narrative

Figures 1a-b show the cruise track and the stations worked during the survey. The vessel departed from Nouakchott on 14 November, starting the sampling work 10 nautical miles (NM) north off Cape Blanc. The hydrographic transect off Cape Blanc was worked on 11 November in the Mauritanian part of the survey. The survey proceeded northwards to about 20 NM northeast off Cape Bojador with an acoustic sampling grid with a transect distance 10 NM apart, covering the shelf and slope down until about 200 m bottom depth (Figure 1a). The survey was interrupted with a call at Las Palmas 26-28 November for refuelling. The survey resumed about 50 NM south off Laayoune in the late evening of 28 November. The sampling continued northwards in a zigzag pattern towards Cape Juby. Northwards from Cape Juby the inner shelf between Cape Juby and 30°N was covered with a zigzag pattern, while the outer shelf was covered with a more open grid, (Figure 1b).

Intercalibration with the Moroccan research vessel *Al Amir Moulay Abdallah* started about 10 NM east off Cape Juby on 1 December. The two vessels worked in tandem from Cape Juby to Cape Cantin. From 20 NM south off Agadir the survey proceeded northwards with a survey track perpendicular to the coast, transecting the whole shelf. The northern limit of the survey, off Cape Cantin, was reached on 8 December. The vessel called on Agadir on 9 and 10 December for disembarking local scientists and change of crew. The vessel then steamed to Las Palmas where she arrived on 12 December.

Standard hydrographical sections were sampled at Cape Blanc, Cape Barbas, off Dakhla, at Cape Bojador, Cape Juby, Cape Dra and Cape Ghir. Two alongshore-hydrographical sections were worked in bottom depths of 50 and 200 m between Cape Blanc and Lacraa. In addition a hydrographical section was worked off Lacraa.

The weather was favourable and put no constraints on the sampling work.

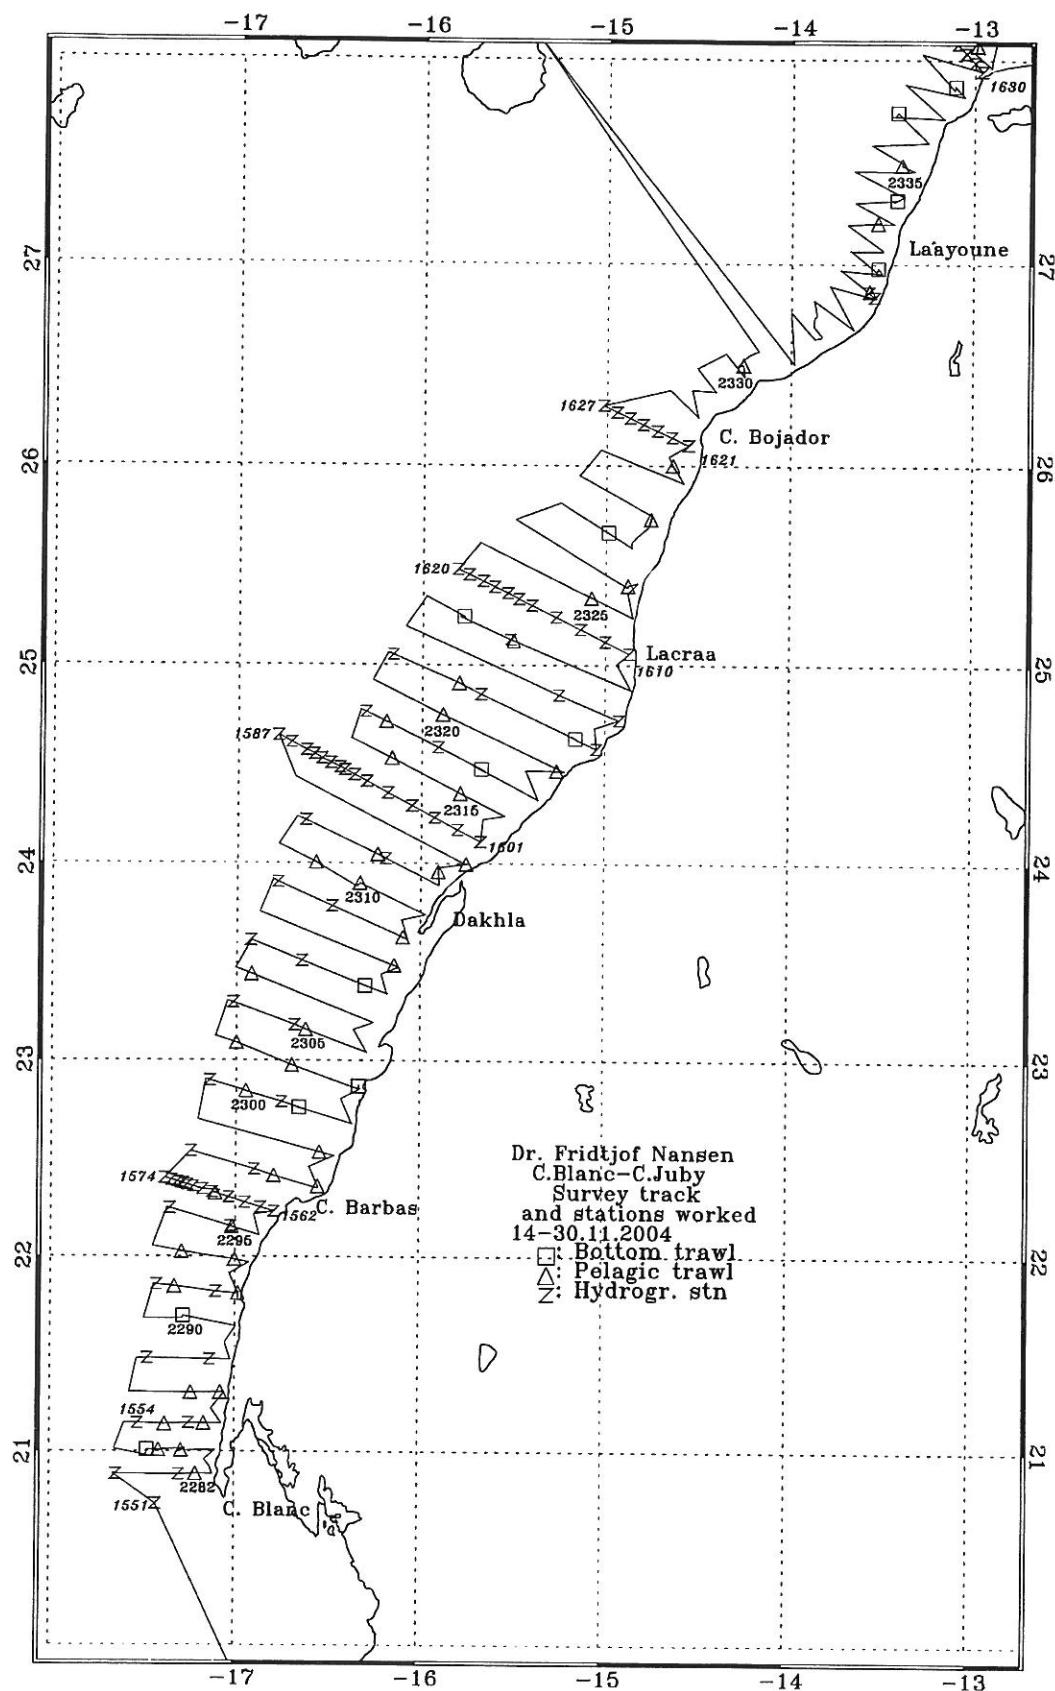

Figure 1a. Course track with fishing and hydrographic stations, Cape Blanc to Cape Juby. Depth contours at 20 m, 50 m, 100 m, 200 m and 500 m are indicated.

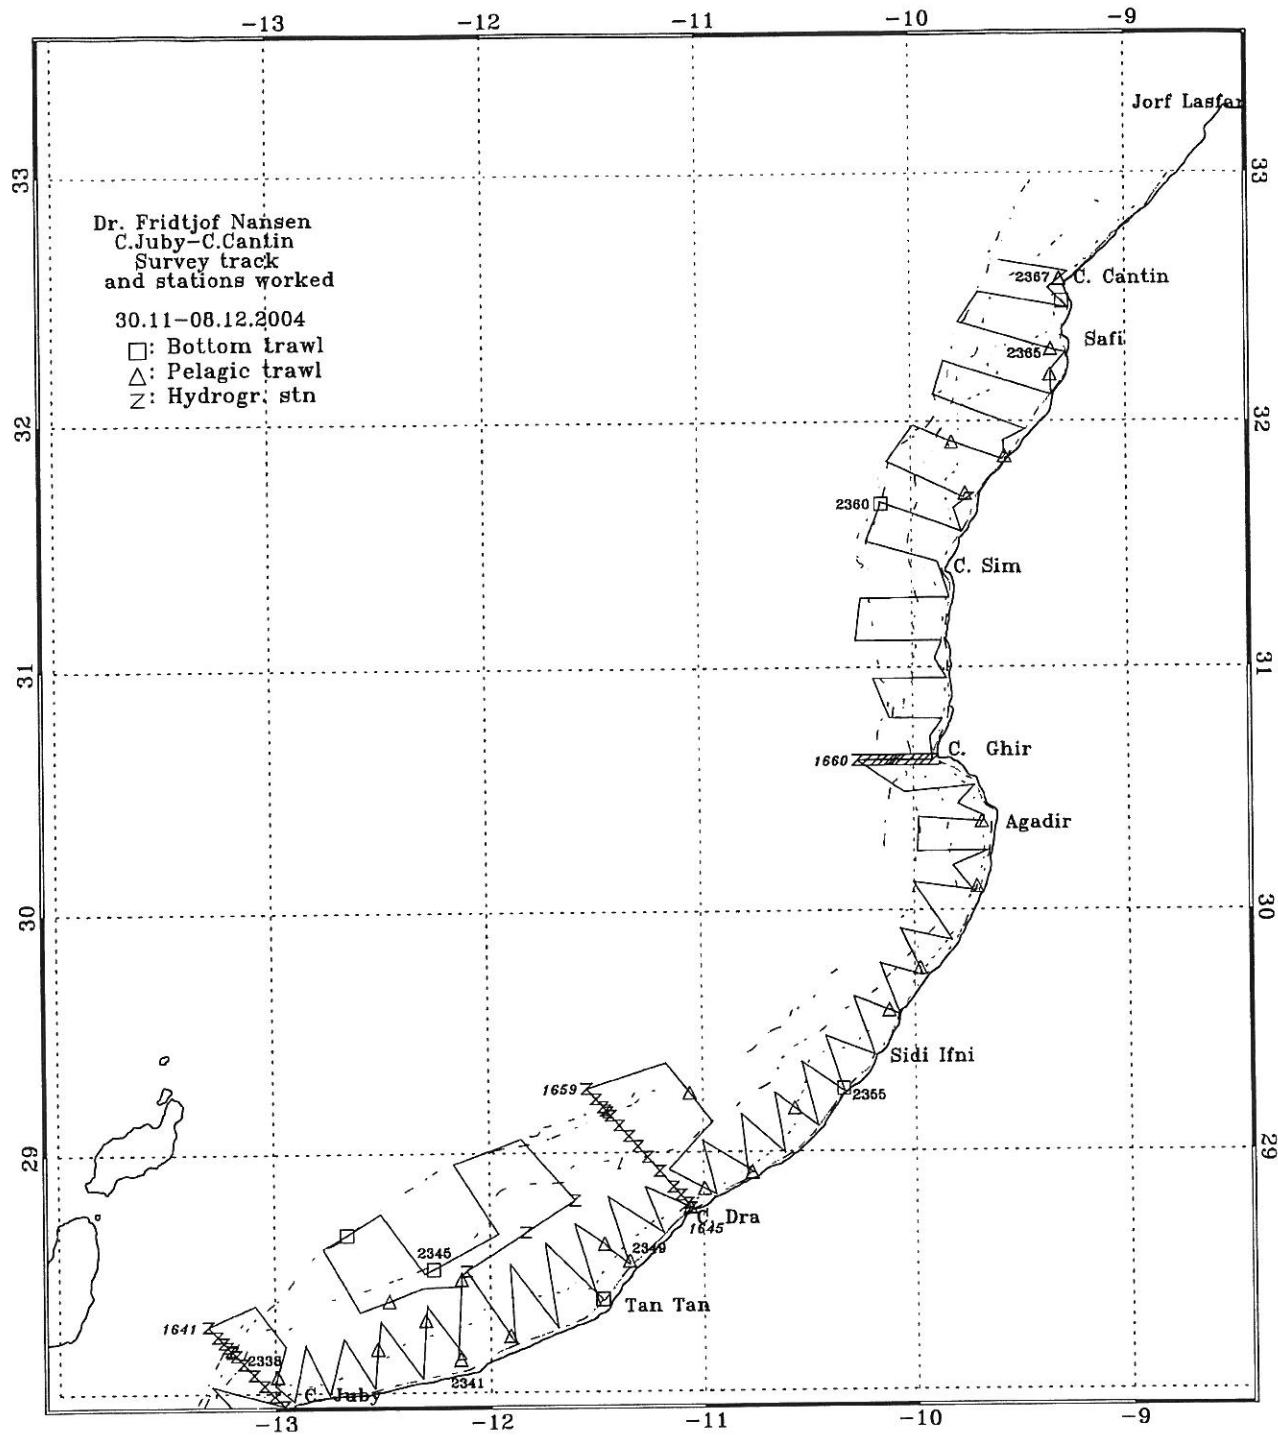

Figure 1b. Course track with fishing and hydrographic stations, Cape Juby to Cape Cantin. Depth contours as in Fig. 1a.

## 1.4 Methods

The cruise followed the standard methods established for the regional surveys:

### *Environmental Data*

Meteorological observations including wind direction and speed, air temperature, solar radiation and sea surface temperature (SST) were automatically logged and recorded with position and bottom depth every nautical mile sailed using an Aanderaa meteorological station. Sea surface salinity (SSS) was obtained by means of a Seabird 21 thermosalinograph measuring the engine intake water from a depth of 5 meters. The raw salinity data, which this instrument stores at a high sampling rate of one data cycle per second were prior to the analysis reduced to 0.5 nautical mile spatial averages. Vertical profiles of temperature, salinity and oxygen were recorded with a Seabird 911+ CTD probe. Real time plotting and logging was done using the customised Seabird Seasave software installed on a PC. The profiles were in general taken down to a few meters above the bottom. In deep stations, however, data logging was interrupted at 500 m. Niskin bottles were triggered for water samples, one near the surface and one near the bottom, in order to calibrate the oxygen and salinity sensors. The water samples were analysed for dissolved oxygen using the Winkler method, and for salinity using a Guildline Portasal salinometer mod. 8410.

### *Biological Sampling*

Biological sampling of the fish was carried out using trawls. A pelagic trawl with floats was often used. A smaller pelagic trawl or the bottom trawl with floats was used for sampling the pelagic fish in very shallow waters (depth less than 25 m). Annex II gives a description of the instruments and the fishing gear used. All catches were sampled for composition by weight and numbers of each species caught. Species identification was based on the FAO Species Guides. Length frequency distributions, by total fish length in cm, of the selected target species were taken in all the stations where they were present. The complete records of fishing stations are shown in Annex I. Sardine otoliths were collected and preserved for later reading ashore. Some readings of the otoliths were carried out during the survey.

The following target groups were used for Morocco:

- 1) Sardine (European pilchard *Sardina pilchardus*),
- 2) Sardinellas (flat sardinella *Sardinella maderensis* and round sardinella *S. aurita*),
- 3) Anchovy (European anchovy *Engraulis encrasicolus*),
- 4) Horse mackerels (Atlantic horse mackerel *Trachurus trachurus*, Cunene horse mackerel *T. trecae* and also including false scad *Caranx rhonchus*),
- 5) Mackerels (chub mackerel *Scomber japonicus*)

- 6) Other pelagic scombrids, carangids and associated species (such as *Auxis* sp., *Caranx* sp. and largehead hairtail *Trichiurus lepturus*), BEI group PEL2
- 7) Other demersal species (such as Sparidae, Haemulidae and Merluccidae).

#### *Acoustic Sampling*

A SIMRAD EK500 Echosounder was used and the echograms were stored on both paper and files. The acoustic biomass estimates were based on the integration technique. The Bergen Integrator (BEI) was used for analysis and allocation of the integrated  $s_A$ -values (average area back scattering coefficient in  $m^2/NM$ ) to the individual specified target groups, usually by 5 NM intervals. Where bottom detection was poor and where fish schools were located very close to the bottom, the bottom echo was sealed off from the fish registrations by manual contouring. The splitting and allocation of the integrator outputs ( $s_A$ -values) was based on a combination of a visual scrutiny of species characteristics as deduced from echo diagrams, the BEI analysis, and the catch compositions.

In cases where the target category of fish contains more than one species (sardinellas and horse mackerels), the mean  $s_A$ -value allocated to the category is divided between the species in the same ratio as their relative contribution to the mean back scattering strength in the length frequency samples.

The following target strength (TS) function was applied to convert allocated  $s_A$ -values (average integrator value, or area back scattering coefficient for a given species or group of species in a specified area) to number of fish:

$$TS = 20 \log L - 72 \text{ dB} \quad (1)$$

which can be converted (see Toresen *et al.* 1998 for details) to the area form (scattering cross sections of acoustic targets):

$$C_{Fi} = 1.26 \cdot 10^6 \cdot L_i^{-2} \quad (2)$$

where  $L_i$  is total length in 1 cm length group  $i$  and  $C_{Fi}$  ( $m^{-2}$ ) is the reciprocal back scattering cross section, or so-called fish conversion factor. In order to split and convert the allocated  $s_A$ -values ( $m^2/NM^2$ ) to fish densities (numbers per length group per  $NM^2$ ), the following formula was used:

$$\rho_i = s_A \cdot \frac{p_i}{\sum_{i=1}^n \frac{p_i}{C_{Fi}}} \quad (3)$$

where  $\rho_i$  = density ( $n/NM^2$ ) of fish in length group  $i$   
 $s_A$  = mean integrator value ( $m^2/NM^2$ )  
 $p_i$  = proportion of fish in length group  $i$

$\sum_{i=1}^n \frac{P_i}{C_{Fi}}$  = the relative back scattering cross section ( $m^2$ ) of the length frequency sample of the target species, and

$C_{Fi}$  = reciprocal back scattering cross section ( $\sigma_{bs}^{-1}$ ) of a fish in length group  $i$

For TS= 20log L- be 72 the formula can further simplified into:

$$\rho_i = 1261217 \cdot \frac{n_i}{s_A \frac{\max_{i=\min} n_i l_i^2}{\sum_{i=\min} n_i l_i^2}} \quad (4)$$

where  $s_A$  = mean integrator value of a species within an aggregation area, in  $m^2/NM^2$

$n_i$  = frequency count of length group  $i$  in a pooled representative sample from the distribution area.

$l_i$  = mid length of fish in length group  $i$ .

The constant 1261217 incorporates the offset constant -72 in equation (1). For other TS relationships the equation constant becomes as in box. The table is presented to facilitate a recalculation in case more accurate TS measurements are provided in the future:

Using equation (4), the pooled length distribution is used together with the mean  $s_A$ -value to calculate the density by length groups for each observed area with fish aggregations. The total number, by length groups, in an area is obtained by multiplying the densities with the distribution area. Areas were calculated on the maps by using a digital planimeter (Tamaya Planix 7).

TS constant	Equation constant
-74	1998895
-73	1587779
-72	1261217
-71	1001821
-70	795774
-69	632106
-68	502099

The number of fish was converted to biomass by length group using the estimated weight at length from the length-weight relationship:

$$\bar{w} = \frac{cond}{100} * L^3 \quad (3)$$

The specific condition factors obtained from the samples and applied for this survey were: 0.82 for sardine, 0.94 for *S. aurita*, 0.97 for *S. maderensis*, 0.54 for *Engraulis encrasiculus* and 0.84 for horse mackerel and chub mackerel.

Finally the total biomass estimate is obtained by summing the biomass by length group and areas within each sector of the survey.

Equations (1), (2) and (3) show that the conversion from  $s_A$ -value to number of fish is dependent on the length composition of the fish. In general there are many problems associated with getting representative length distributions when the various size classes mix with varying proportions between neighbouring stations. When the size classes are well and homogenously mixed in an area, the various length distributions are pooled together with equal importance. In areas where fish size-groups are well segregated, separate estimates are made for each group. Otherwise, when the size distribution varies from sample to sample, a weighting factor is applied that takes into account the density at the location. In most cases, the mean acoustic density at the location of the sample is the most representative index of this fish density.

For the estimation of the biomass of target group 3) carangids and associated species, an overall average length of 23 cm and a condition factor of 0.88 (to calculate mean weight of this length group) were applied.

A systematic approach to a) produce pooled length distributions of a target species for use in the above equation and b) calculate the biomass estimates for a region, are obtained through the following procedure:

- Each trawl station gets an integrator value as a density index for the sampling site.
- Representative length distributions are selected from all the collected samples of a fish aggregation.
- The mean back scattering strength of a fish in each of these length frequency distributions is calculated.
- The selected length distributions are then pooled using the ratio between the allocated  $s_A$ -value and the mean back scattering strength as the weighting factor. (If the size distribution is geographically uniform the three steps mentioned above can be skipped and the samples are pooled together with equal importance.)
- The pooled length distribution is used together with the mean  $s_A$ -value to calculate the biomass in numbers by length groups, for each area in the map, using formula (4) above. Numbers are converted to weight using the condition factor of the species. This can be calculated from the length samples where the total weight of the sample is recorded, or from individual biological samples.
- Biomass is calculated as the product of the density and the area of the aggregation, and finally the area-related biomass values in a region are summed together.

The necessary calculations are done in spreadsheets after the scientist has completed the two first steps in the above list manually.

All data on fishing stations and fish length sampling were made available to the participants from the local research institutes on diskettes.

## CHAPTER 2 SURVEY RESULTS

---

### 2.1 Hydrographic conditions

#### *Wind conditions*

The wind conditions encountered during this survey were within the calmest ever experienced during the Dr. Fridtjof Nansen surveys in the region. According to the long-term climatic trend for this region, late November and December would be characterized by a change in the wind pattern between the south and the north. To the south of Cape Juby, the conditions would be characterised by an increase in the average wind speed and in the duration of the north-easterly wind events related to the trades. To the north of Cape Juby, the winter period of trade winds relaxation would be expected with fewer and shorter wind events from variable directions. The conditions experienced during this survey were the reverse to such pattern and, climatologically, were more typical to the late October situation. The calmer wind conditions, shorter duration of events, more variable wind directions were experienced south of Cape Juby, while in the north a moderate but persistently northerly wind had prevailed during the survey period.

The summary of the wind conditions is shown in Figures 2. From Cape Blanc to Dakhla (Figure 2a) the dominant wind directions were between north and east with each wind event lasting no more than a day. The average wind speed stayed within the limit of 5 to 6 m/s. A more persistent north-easterly wind event took place from the 20 to 24 November, when the ship was surveying the region enclosed between the Dakhla and Lacraa hydrographic lines (Figure 1). In this case, the average wind speed was 9.5 m/s. On 25 November in the morning, when surveying south of Cape Bojador, the vessel was hit by a strong easterly wind associated to a Sahara Dust event. The average wind speed increased to 11 m/s. The horizontal visibility diminished to few hundreds meters and beyond that distance a yellowish wall of dust was erected and obscured the view. The air temperature arose from 20 to above 25 °C. The ship's deck was invaded by numerous, 10-centimeter long red-coloured grasshoppers of the locust kind, blown from Sahara with the easterly wind. This situation persisted until the next day, when the ship left the survey area for refuelling in Las Palmas. Away from the coast the visibility has returned, but the strong easterly wind had persisted throughout the whole journey to Las Palmas. Upon the return to the survey region, from Cape Bojador and Cape Juby, the dominant wind direction turned to southwest with the average wind speed in the range of 7-8 m/s.

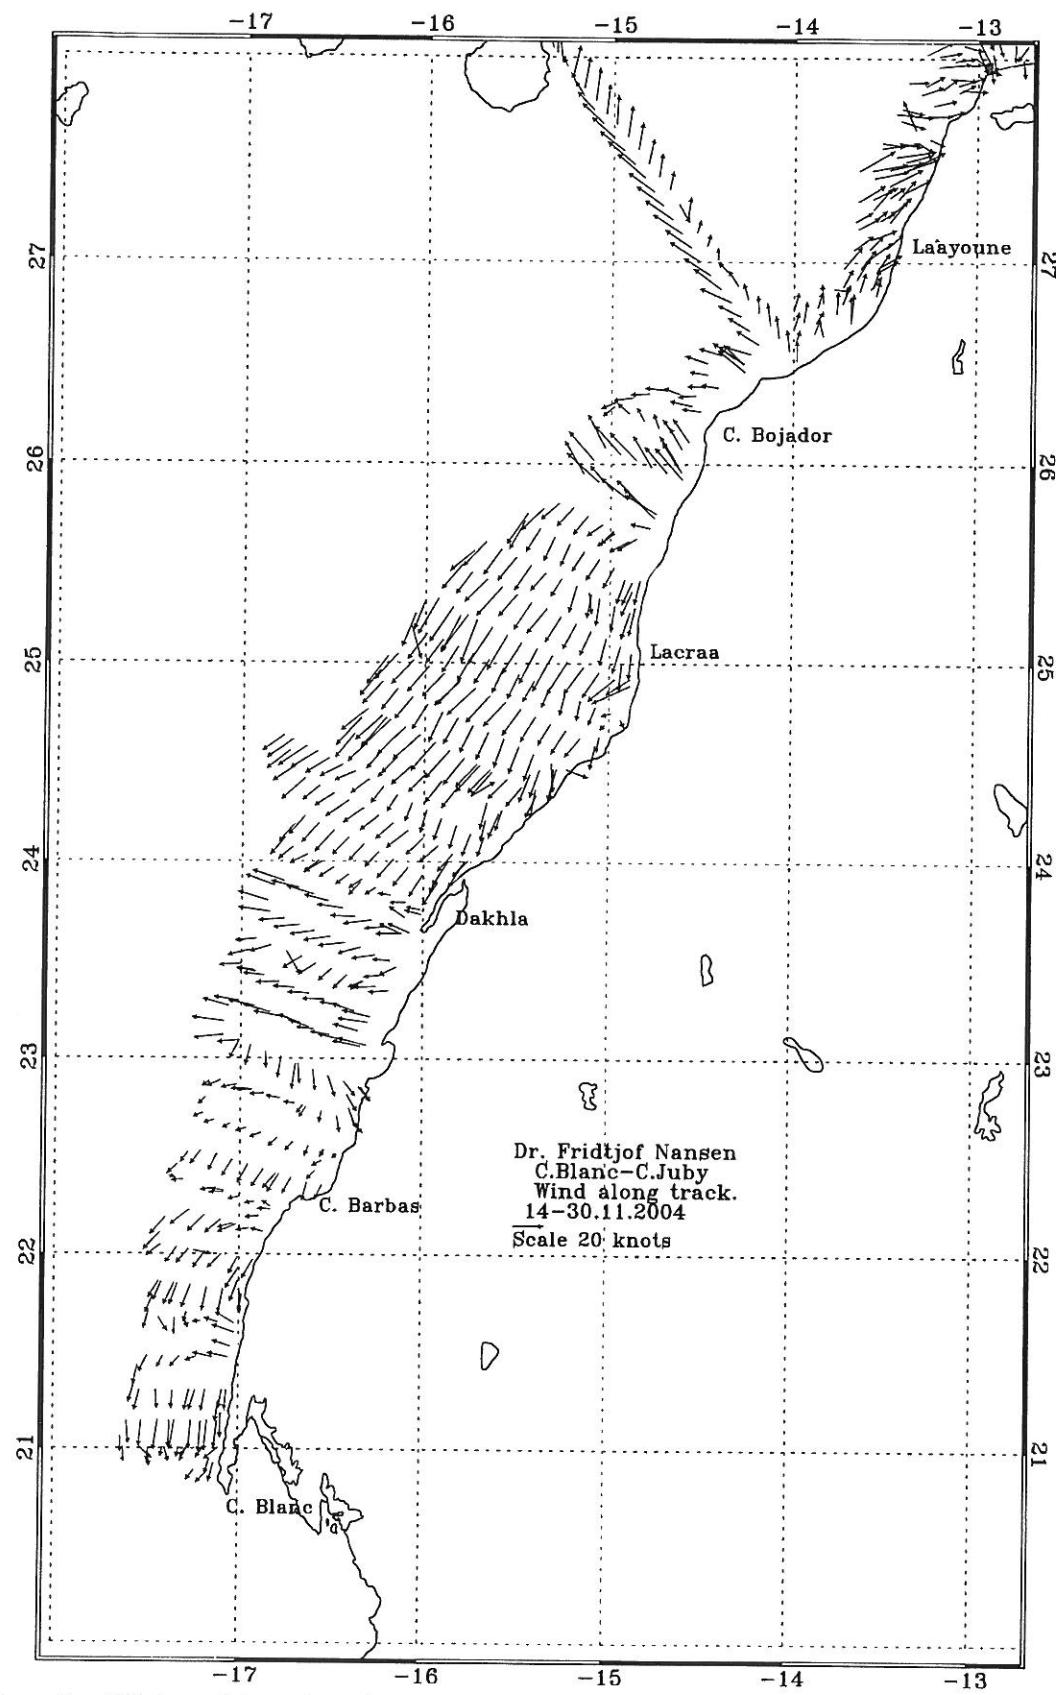

Figure 2a. Wind conditions along the survey, Cape Blanc to Cape Juby. Depth contours as in Fig. 1a.

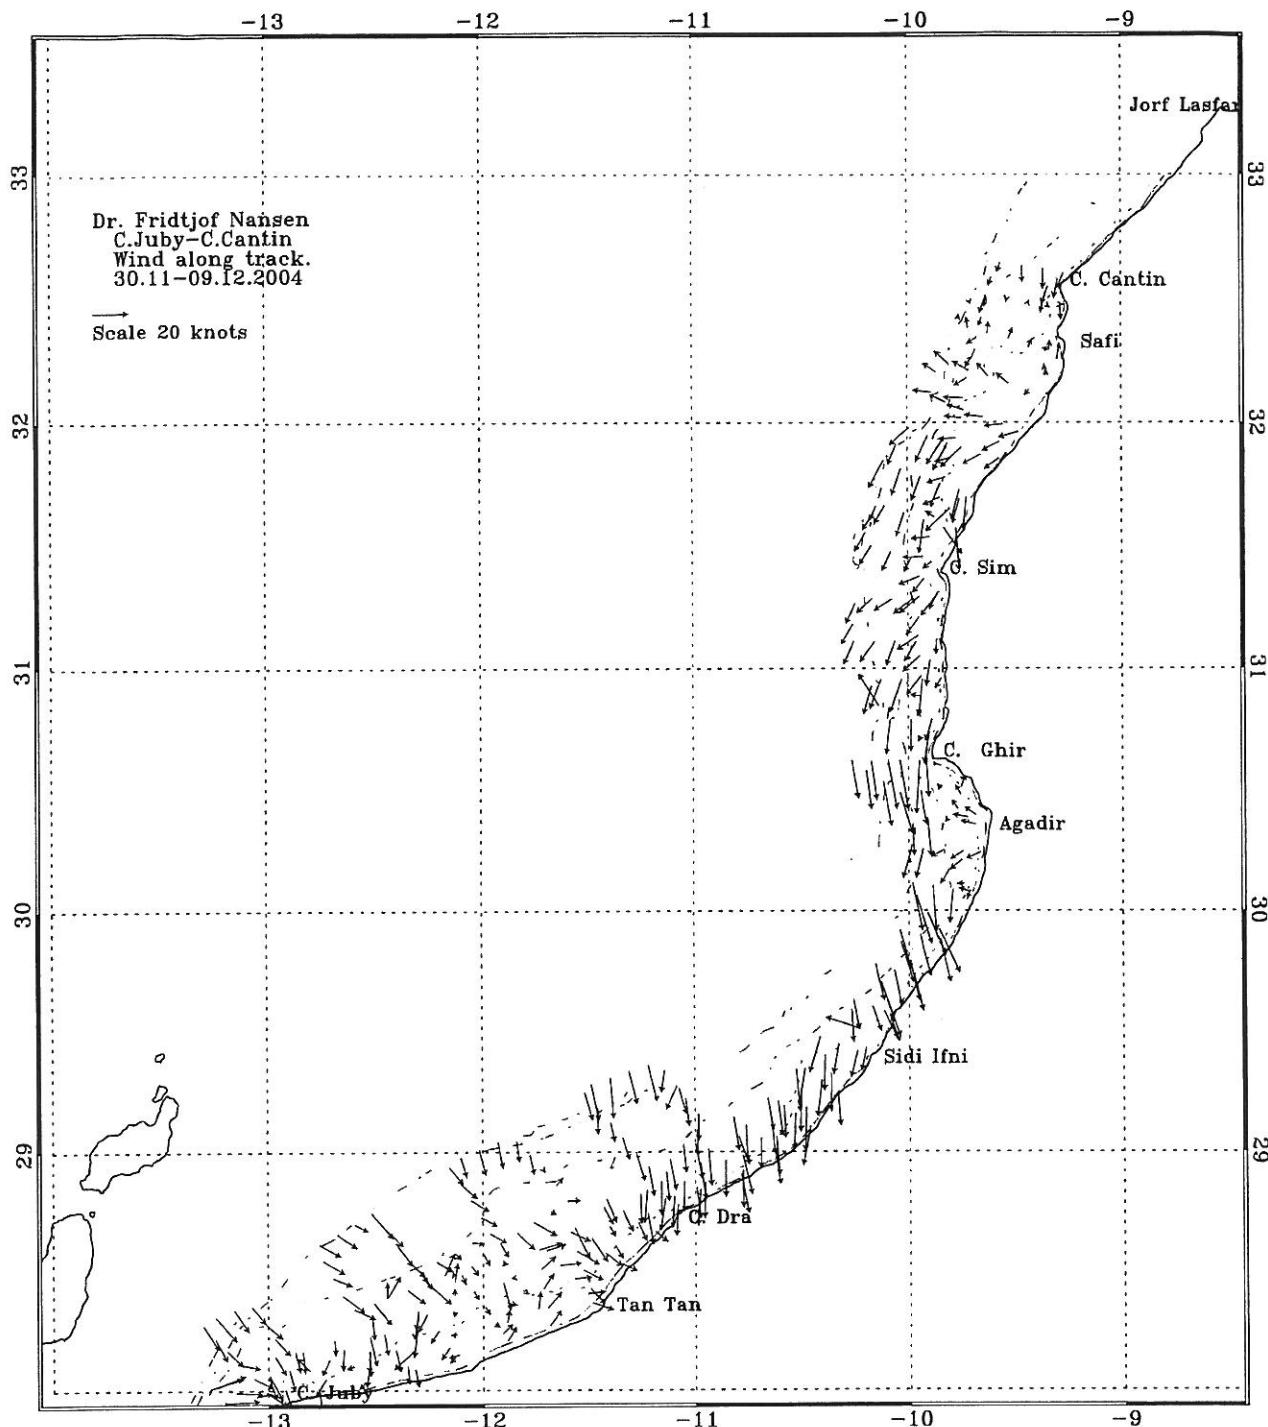

Figure 2b. Wind conditions along the survey, Cape Juby to Cape Cantin. Depth contours as in Fig. 1a.

The wind between Cape Juby and Cape Dra was weak to moderate, predominantly from the northwest (Figure 2b). Despite of the weak wind, the ocean surface was subjected to a strong swell arriving from the north. The similar swell conditions have been observed frequently in the past surveys to occur along this section of the coast independently of the local wind. It may be hypothesized that the swell is in this region a permanent phenomenon, caused by the fact that the Tan Tan coast forms the main barrier to the north-south ocean circulation, which dominates the

regional hydrography. It would be useful to investigate how this persistence of the swell affects the distributions pelagic fish.

It is known (also from this survey data) that the pelagic fish in this region aggregate close to the coast, thus inshore of the shoaling point of the swell wave train. It is possible that the alongshore currents generated by the breaking swell contribute significantly to the patterns of concentration transport and retention that fish is subjected to along this section of the coast.

To the north of Cape Dra, the wind speed increased to about 9 m/s, directed from the north. These conditions persisted for the next two days (the 5 and 6 December) until the survey reached Cape Ghir. From Cape Ghir northwards, the wind speed subsided, but its dominant northerly direction remained unchanged to the latitude 32° N (Figure 2 b).

#### *Hydrography of the shallow waters including upwelling conditions.*

The introduction of the new instrument aboard *Dr. Fridtjof Nansen* to measure sea surface salinity (see Section 1.4) opened new possibilities to determine hydrographic boundaries on the shelf. By combining the sea surface temperature data (SST) with SSS it is possible now to track extents of shallow-water masses, which often determine natural ecological boundaries of pelagic habitats.

Figure 3a demonstrates the distribution of SST in the southern region. Figure 3b, represents the SSS data for the same region. From these figures, one can clearly identify the two major upwelling cell in the area, Cape Blanc, which is located approximately between the latitudes 20°30' and 22° N and Lacraa located between 24°30' and 25°15' N.

Off Cape Blanc, the temperature at the surface was below 18 °C and the salinity dropped below 35.8. This range of values manifested the presence of the subsurface South Atlantic Central Water (SACW) in the upwelled water. The hydrographic line occupied along the 50-meter isobath (Figure 5b) clearly demonstrates the vertical structure of the Cape Blanc upwelling cells in the alongshore direction. The maximum uplift of the bottom waters was located at 22 °N, based on the position of the peak in the elevation of the oxygen distribution. The alongshore extent was about one degree of latitude, as inferred from the shape of the 19 °C isotherm. A sharp hydrographic front just to the south of Cape Barbas, clearly seen on the salinity distribution, separated the upwelling domain from the warmer and more saline water masses of the north. Notice that the location of Cape Blanc upwelling cell as inferred from the hydrographic data matches well the region of co-occurrence of the two major pelagic fish: the sardine and sardinellas obtained from acoustic survey data (Figure 6 and Figure 7).

Off Lacraa, the sea surface temperature, as in the case of Cape Blank, decreased near the coast to less than 18 °C. Salinity displayed a strong cross-shelf gradient, but its inshore value of 36.4 psu was much higher than that observed off Cape Blanc. The higher salinity attributes the origin of the coastal water to North Atlantic Central Water (NACW), a much poorer in nutrients and more saturated with oxygen water mass than SACW. A striking feature of the vertical structure in this region was absence of the vertical stratification of the water column. The two hydrographic lines obtained in this region, off Dakhla (Figure 4c) and Lacraa (Figure 4d) demonstrate that the upwelling fronts were located far away from the coast. The inner shelf waters were entirely mixed, exhibiting a constant temperature, salinity and oxygen from the surface to the bottom. The typical coastal upwelling structure, whereby the water mass near the coast is connected to its shelf-break source through an upsloping bottom layer of a cold and less saline water was not observed. This raises the question about the source of the water masses observed inshore off Lacraa in Figure 3a and 3b. If these waters were brought there by an upwelling event, it must have occurred prior to the survey. However, our survey data suggest for an existence of a perennial coastal current flowing along the coast between Cape Bojador and Lacraa that might be an alternative source bringing the water masses to this coastal region.

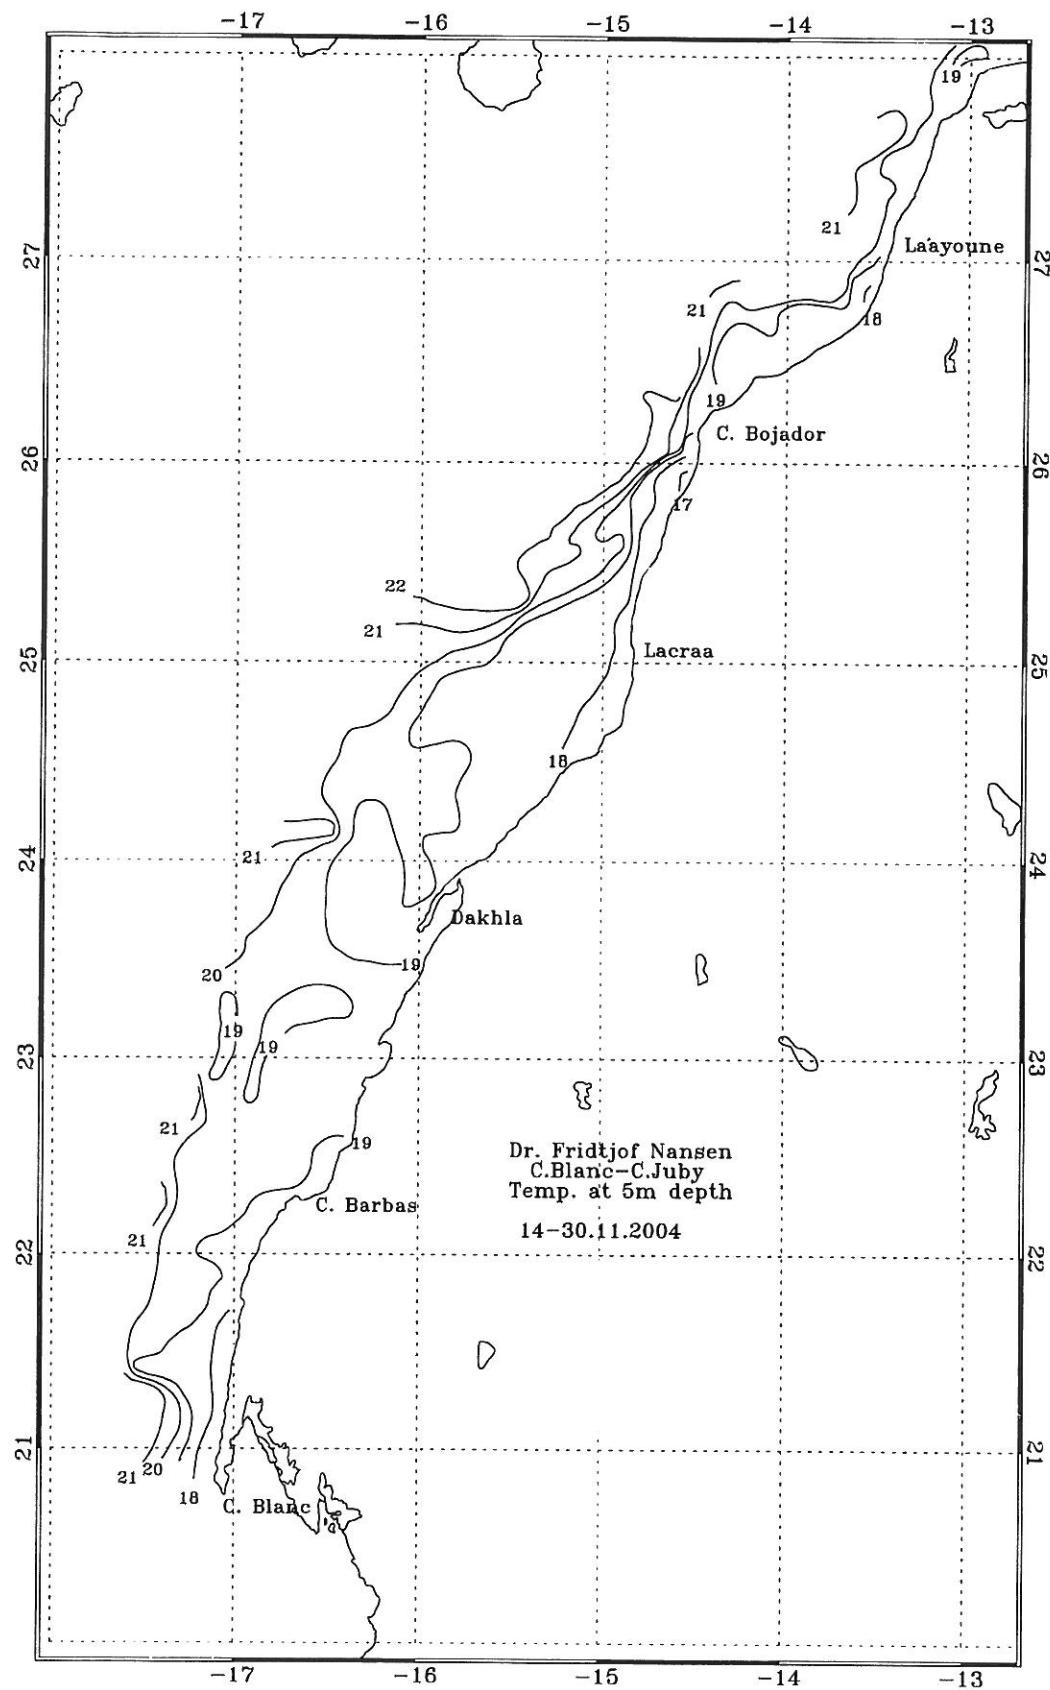

Figure 3a Sea surface temperature (at 5 m depth), Cape Blanc to Cape Juby. Depth contours as in Fig. 1a.

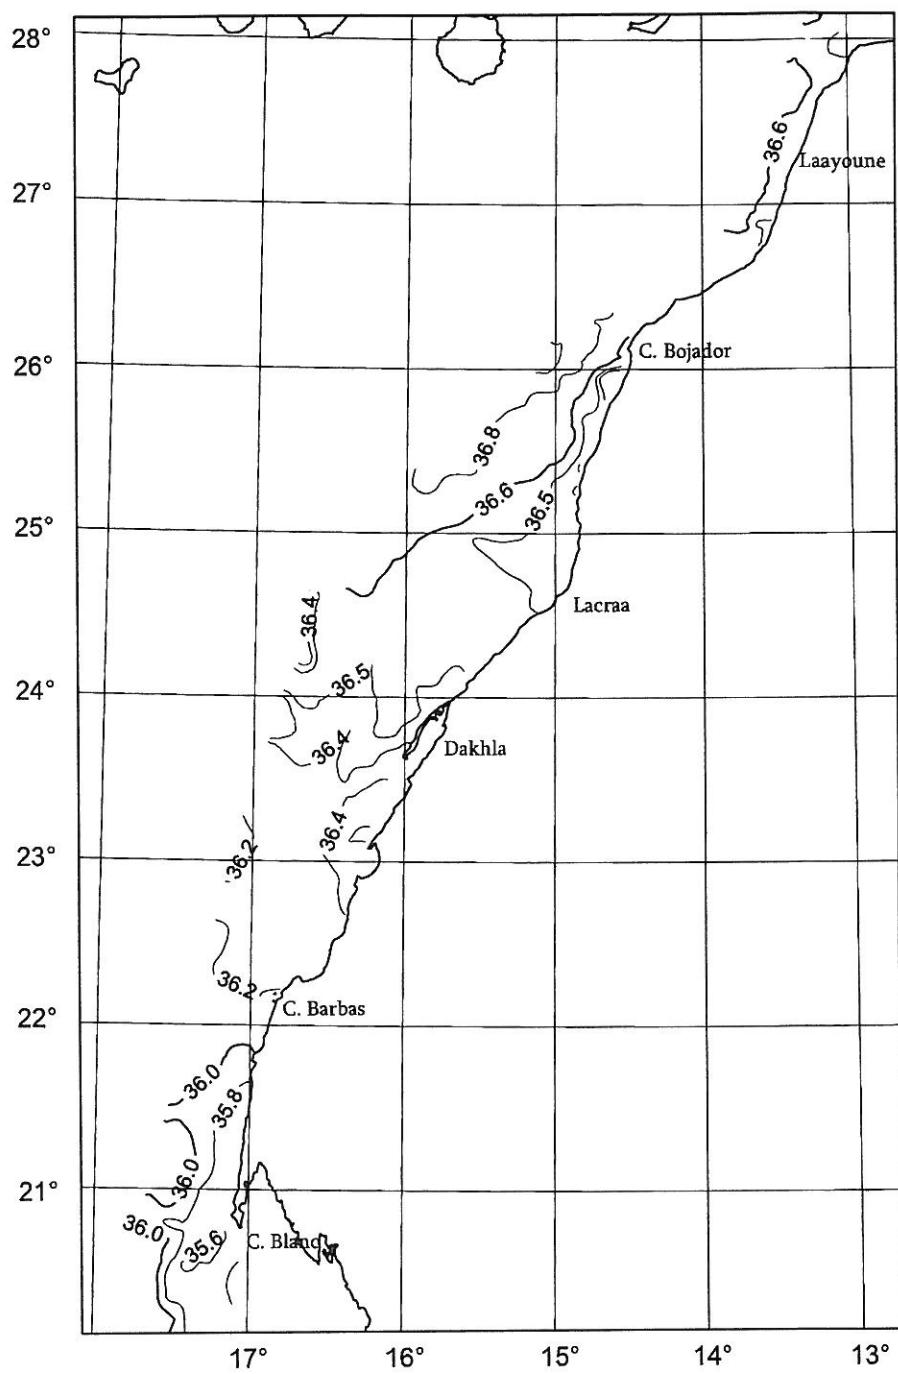

Figure 3b Sea surface salinity (at 5 m depth), Cape Blanc to Cape Juby.

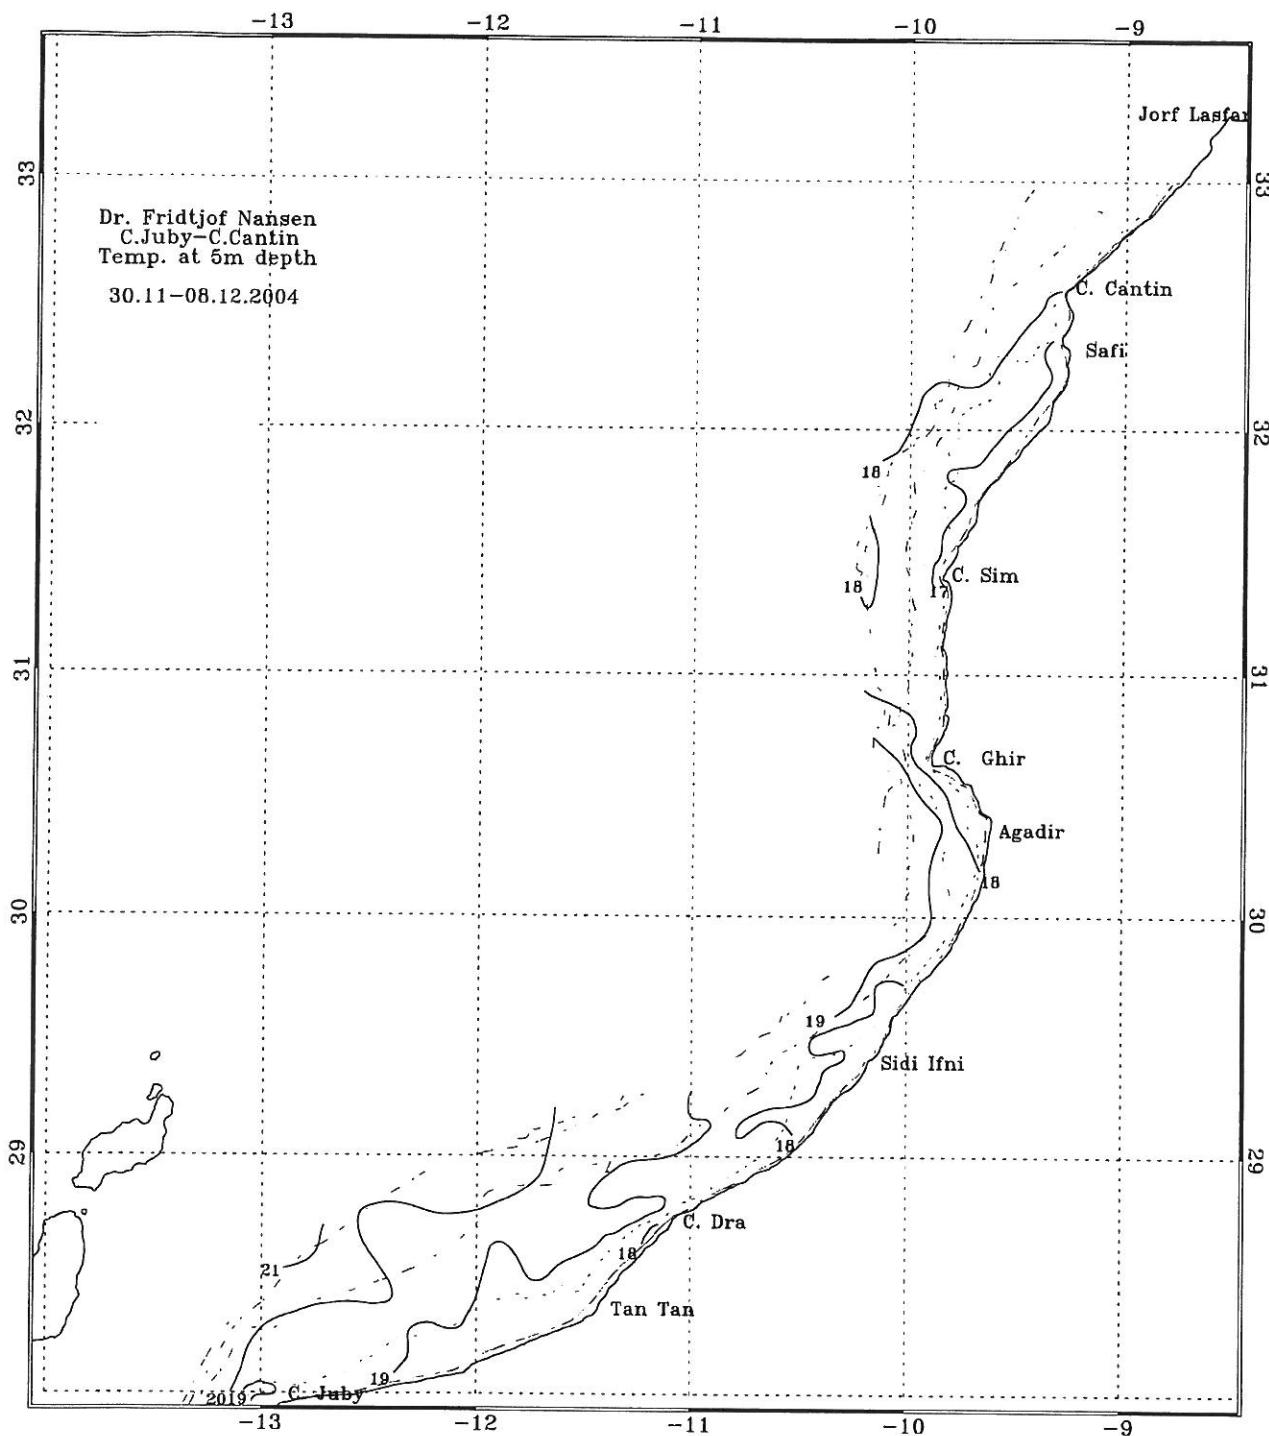

Figure 3c. Sea surface temperature (at 5 m depth), Cape Juby to Cape Cantin. Depth contours as in Fig. 1a.

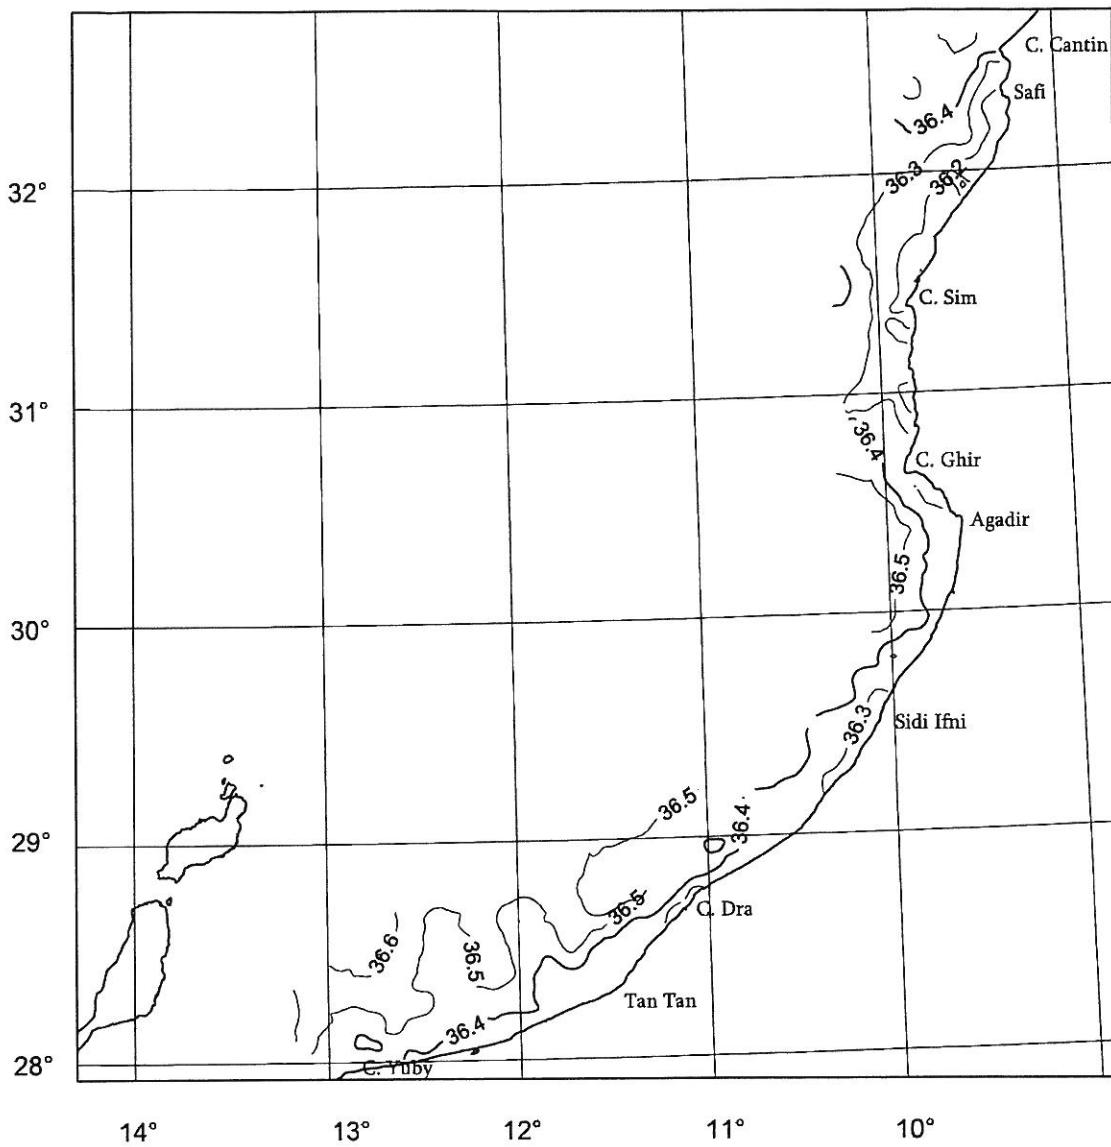

Figure 3d. Sea surface temperature (at 5 m depth), Cape Juby to Cape Cantin.

The acoustic current profiler measurements done during the earlier surveys had revealed a southward alongshore flow to the north of Lacraa and south of Cape Bojador with velocities 0.5 m/s that did not depend on the local wind. The hydrographic data from past surveys made in this region indicate that the absence of the vertical stratification for the depths shallower than 50-60 meter is the typical feature for this shelf. In addition, both the survey data and satellite imagery identify a large warm body of surface waters located just offshore of Cape Bojador, which is characterized by the highest annual SST in the entire Canary Current coastal region. (This feature is also clearly seen in the distributions shown in Figure 3a and 3b). The cross-shelf density gradient associated to this water mass could be a driving force to sustain a perennial current, located close to the coast, responsible for the transport of the cold and low salinity water masses from the north to the Lacraa coastal region. The persistence and variations of such a current would be important to the life-cycles of the sardine, the dominant stock in this region.

The distribution of the sea surface temperature and salinity obtained in the northern region (Figure 3c and 3d), indicated only one large area with a strong upwelling signature, which was located between Cape Sim and Safi. The temperature in this upwelling centre was less than 17 °C and salinity was less than 36.2. The observed upwelling signature did not coincide with the local wind, which was weak during the passage of the surveying vessel. Notice that the height of the upwelling season in this region falls to the summer. Hence, the encounter of such a large and active upwelling cell during the survey period may be treated as an anomaly, which contributes to the notion, expressed earlier in this report, that during 2004 the survey region has experienced a prolonged summer period. Another, a much smaller upwelling cell was found off Sidi Ifni. Within this cell, the observed temperature and salinity were below 18 °C and 36.3, respectively. The rest of the coast in the northern region displayed weak offshore SST and SSS gradients, with the temperature between 18 and 19 °C and salinity between 36.3 and 36.4 near the coast. The maximum offshore temperature > 21°C and salinity > 36.6 °C was recorded at the seaward end of the Cape Juby hydrographic line.

From the hydrographic data collected on the shelf in the northern region (Figure 4f-h), the vertical structure observed off Cape Dra merits a special attention. The bottom topography in that area is characterized by a rapid descent from the coastline to a depth of 60 meters and a relatively flat deep shelf that underlies it. The CTD data from this deep portion has revealed a 10-meter thick near-bottom layer characterized by a rapid drop in oxygen values below 4 ml/l on average and below 3 ml/l at station 1647. The observed values were below those observed in the deep slope waters, hence there is a supposition that the near-bottom low oxygen layer has emerged in the recent period, caused an increased decay of organic matter and poor ventilation of the bottom layer. Further investigation will be necessary to establish whether the process was transient or if it indicates a more permanent change of the coastal environment off Cape Dra.

## 2.2 Distribution of pelagic fish on the shelf from Cape Blanc to Cape Juby.

Figures 6 to 10 show the distribution of the main groups of pelagic fish by contoured acoustic densities.

**Sardine**, *Sardina pilchardus*, was found almost without interruption between Cape Blanc and Cape Juby, Figure 6. The density of sardine between Cape Blanc and Cape Barbas was higher compared to November 2003. The aggregations between Cape Barbas and Lacraa are covering most of the shelf. In previous years only patches of sardine were found around Cape Bojador, while during this survey it was found in a continuous coastal belt northwards to Cape Juby. Many fishing vessels were active with floating gillnets from about 40 NM south off Cape Bojador to about 30 NM north off the cape. Juvenile sardine was recorded at a very low level south off Cape Bojador, Figure 11a. Between Cape Bojador and Cape Juby it was recorded in high abundance close to the shore. These aggregations consisted mainly of young fish, Figure 11b.

**Sardinellas** (*Sardinella aurita* and *S. maderensis*) formed a major aggregation between Cape Blanc and Cape Barbas. Further north scattered recordings of sardinella were observed near Dakhla and between Lacraa and Cape Bojador, Figure 7. The aggregation between Lacraa and Cape Bojador was consisting mainly of *S. maderensis*.

**Anchovies** (*Engraulis encrasicolus*) were only found between Cape Blanc and Dakhla, and near Laayoune, Figure 8.

**Horse mackerels** (*Trachurus trachurus* and *T. trecae*) were common between Cape Blanc and Cape Barbas, with high densities on the shelf north of Cape Blanc, Figure 9. These aggregations were mainly consisting of *T. trecae*. Further north, between Dakhla and Cape Bojador, the horse mackerel were found on the outer shelf and were mainly made up of *T. trachurus*. Horse mackerel were also recorded Laayoune and Cape Juby, but only at low densities, Figure 9.

**Chub mackerel** (*Scomber japonicus*) was recorded almost continuously from 23°N to Cape Juby and was mainly hit at low densities, Figure 10.

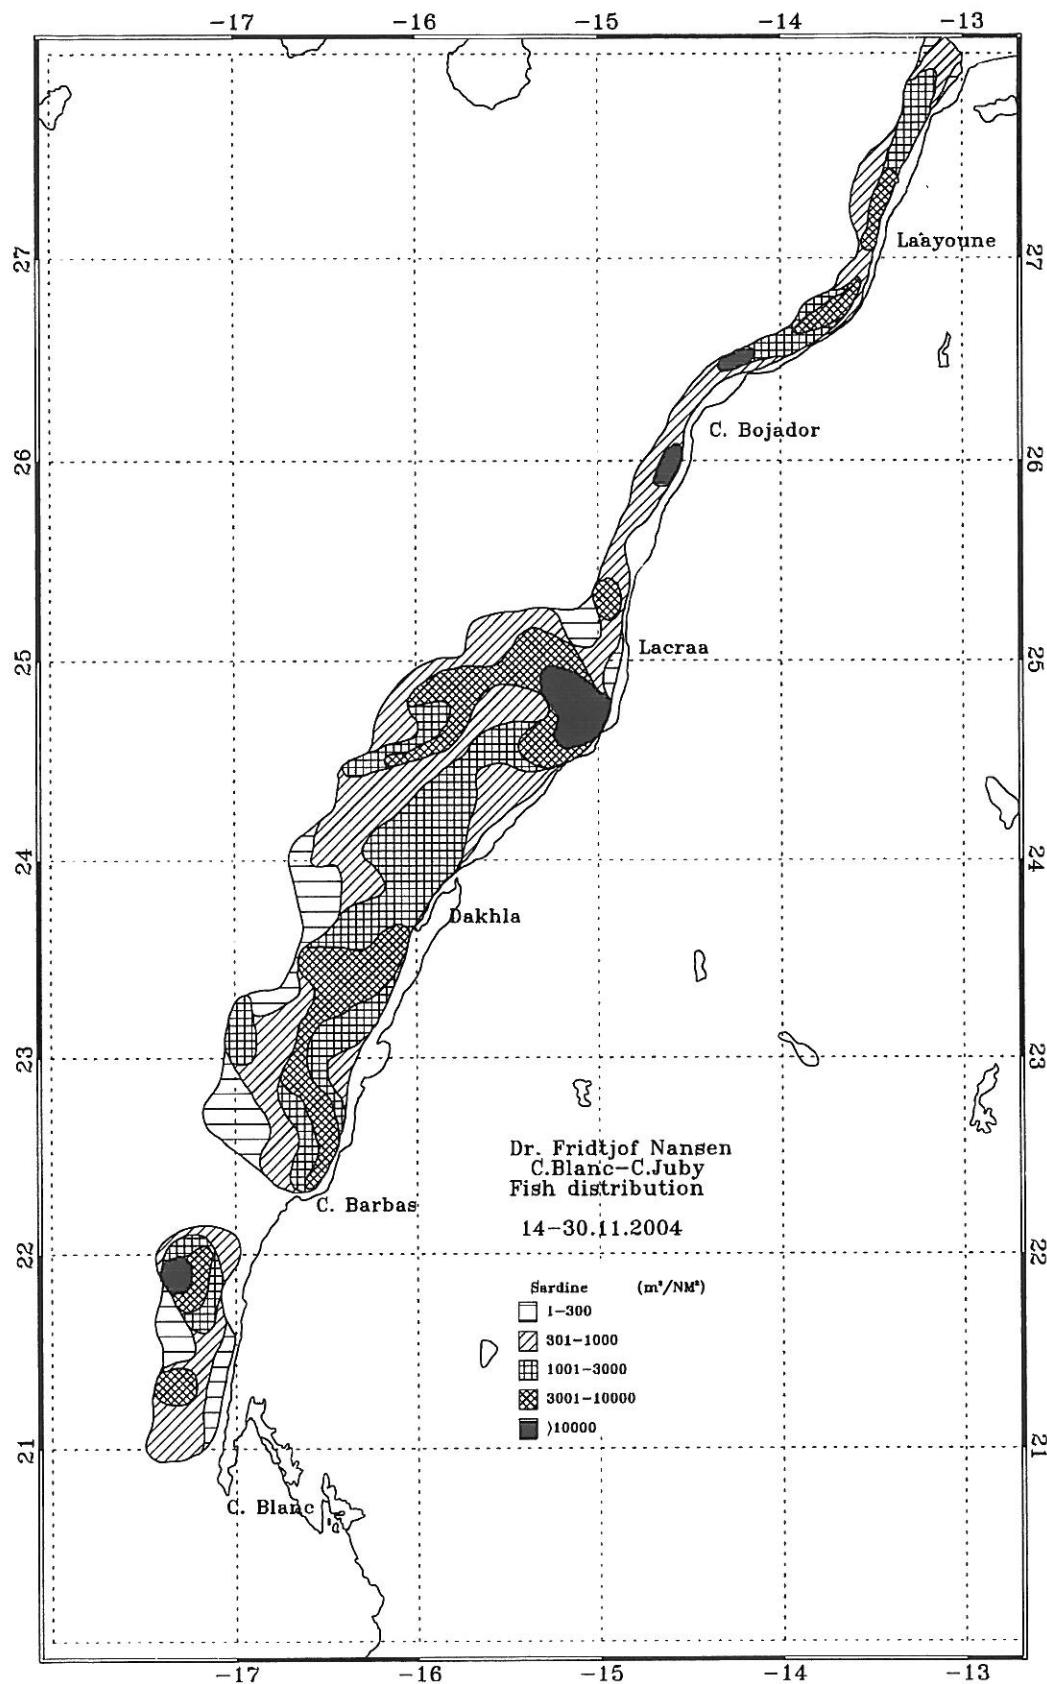

Figure 6. Distribution of sardine, Cape Blanc to Cape Juby. Depth contours as in Fig. 1a.

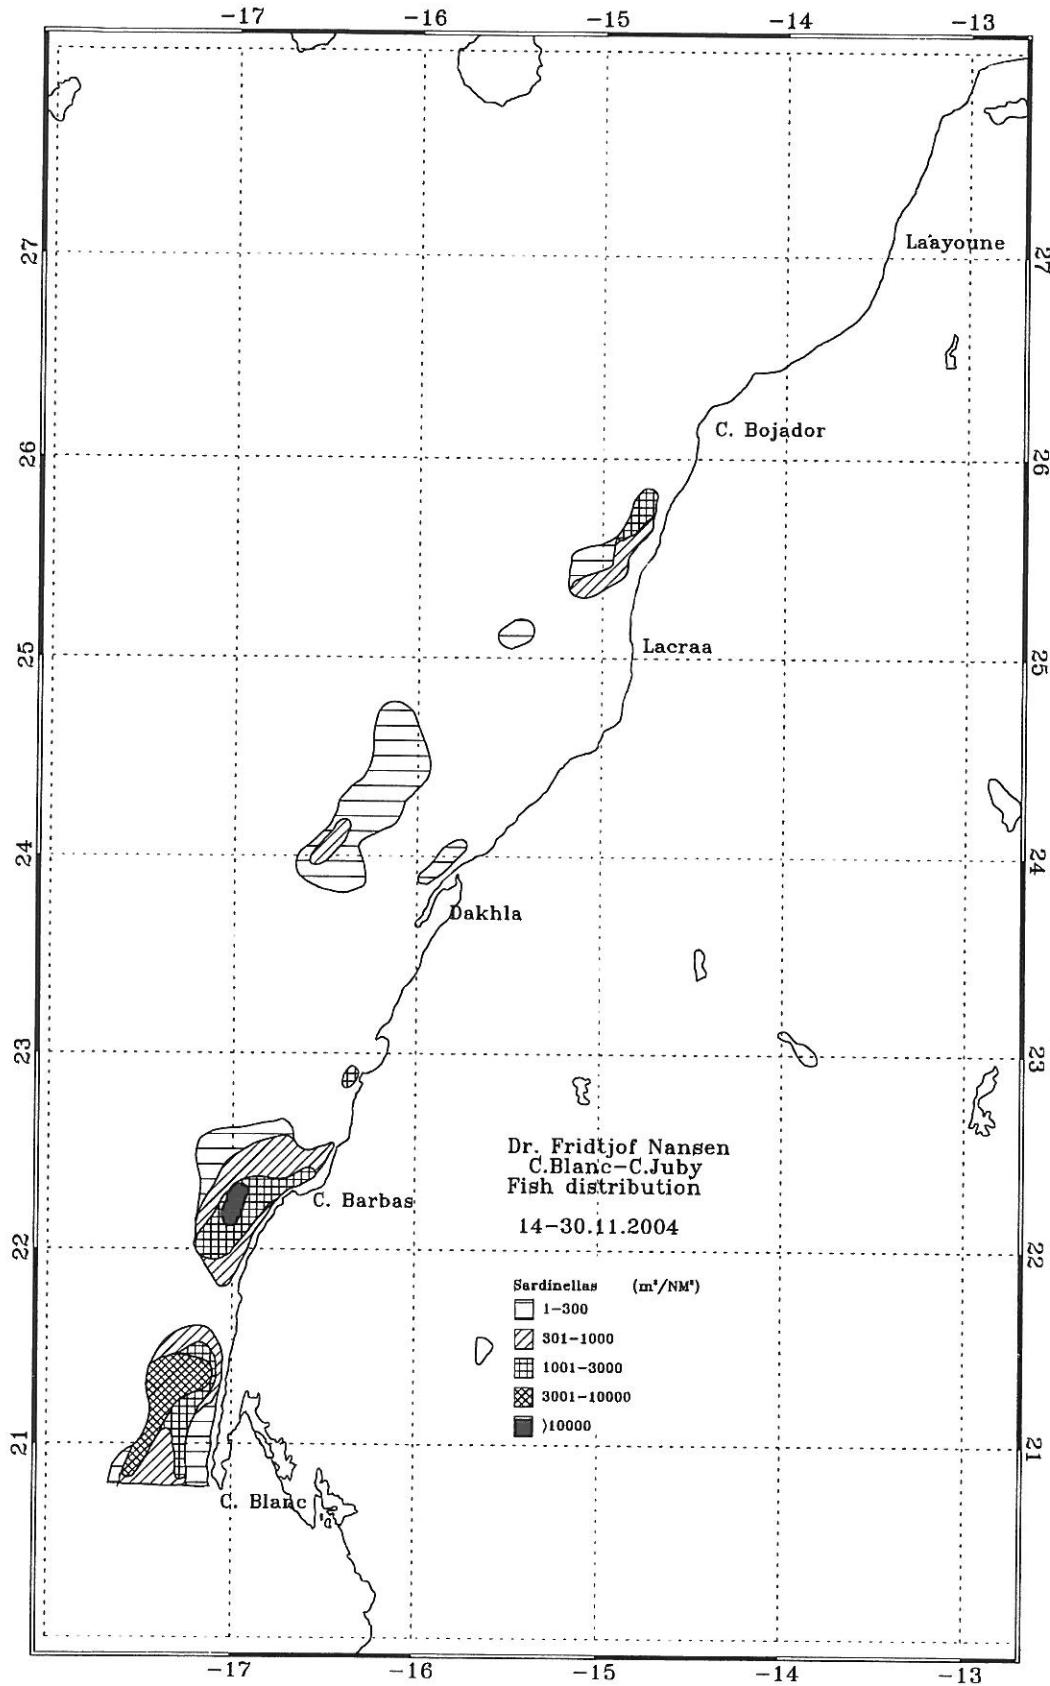

Figure 7. Distribution of sardinella, Cape Blanc to Cape Juby. Depth contours as in Fig. 1a.

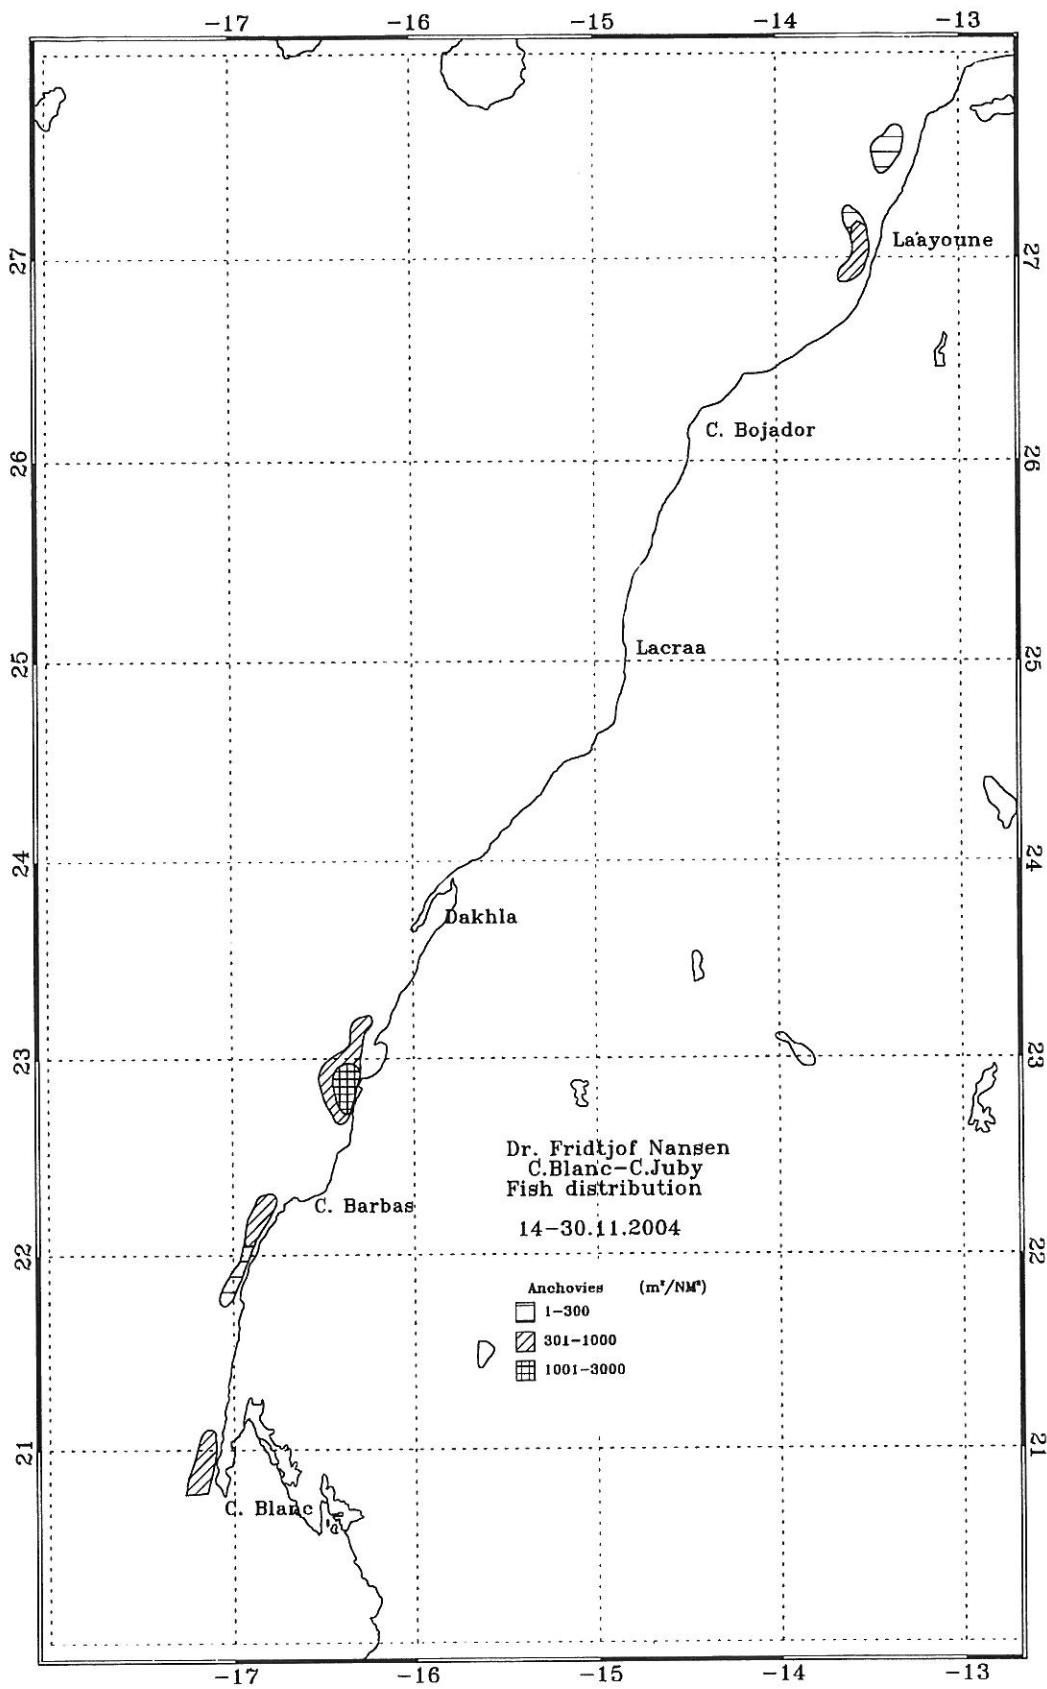

Figure 8. Distribution of anchovy, Cape Blanc to Cape Juby. Depth contours as in Fig. 1a.

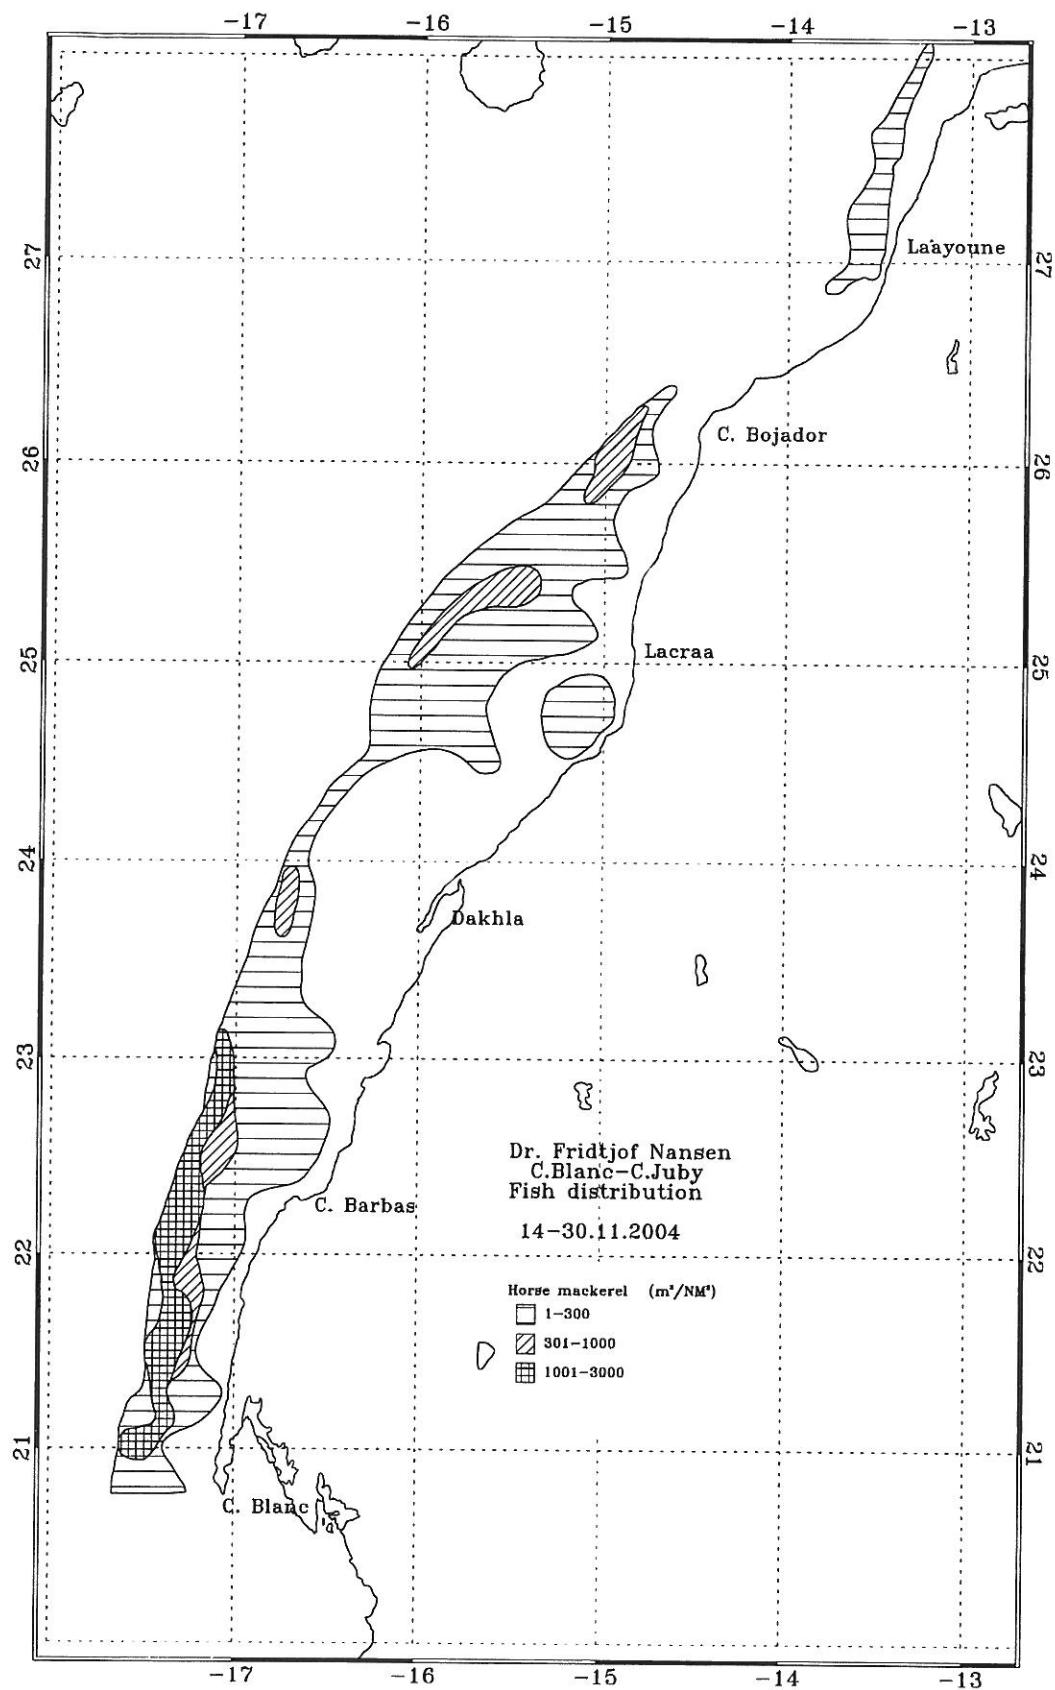

Figure 9. Distribution of horse mackerel, Cape Blanc to Cape Juby. Depth contours as in Fig. 1a.

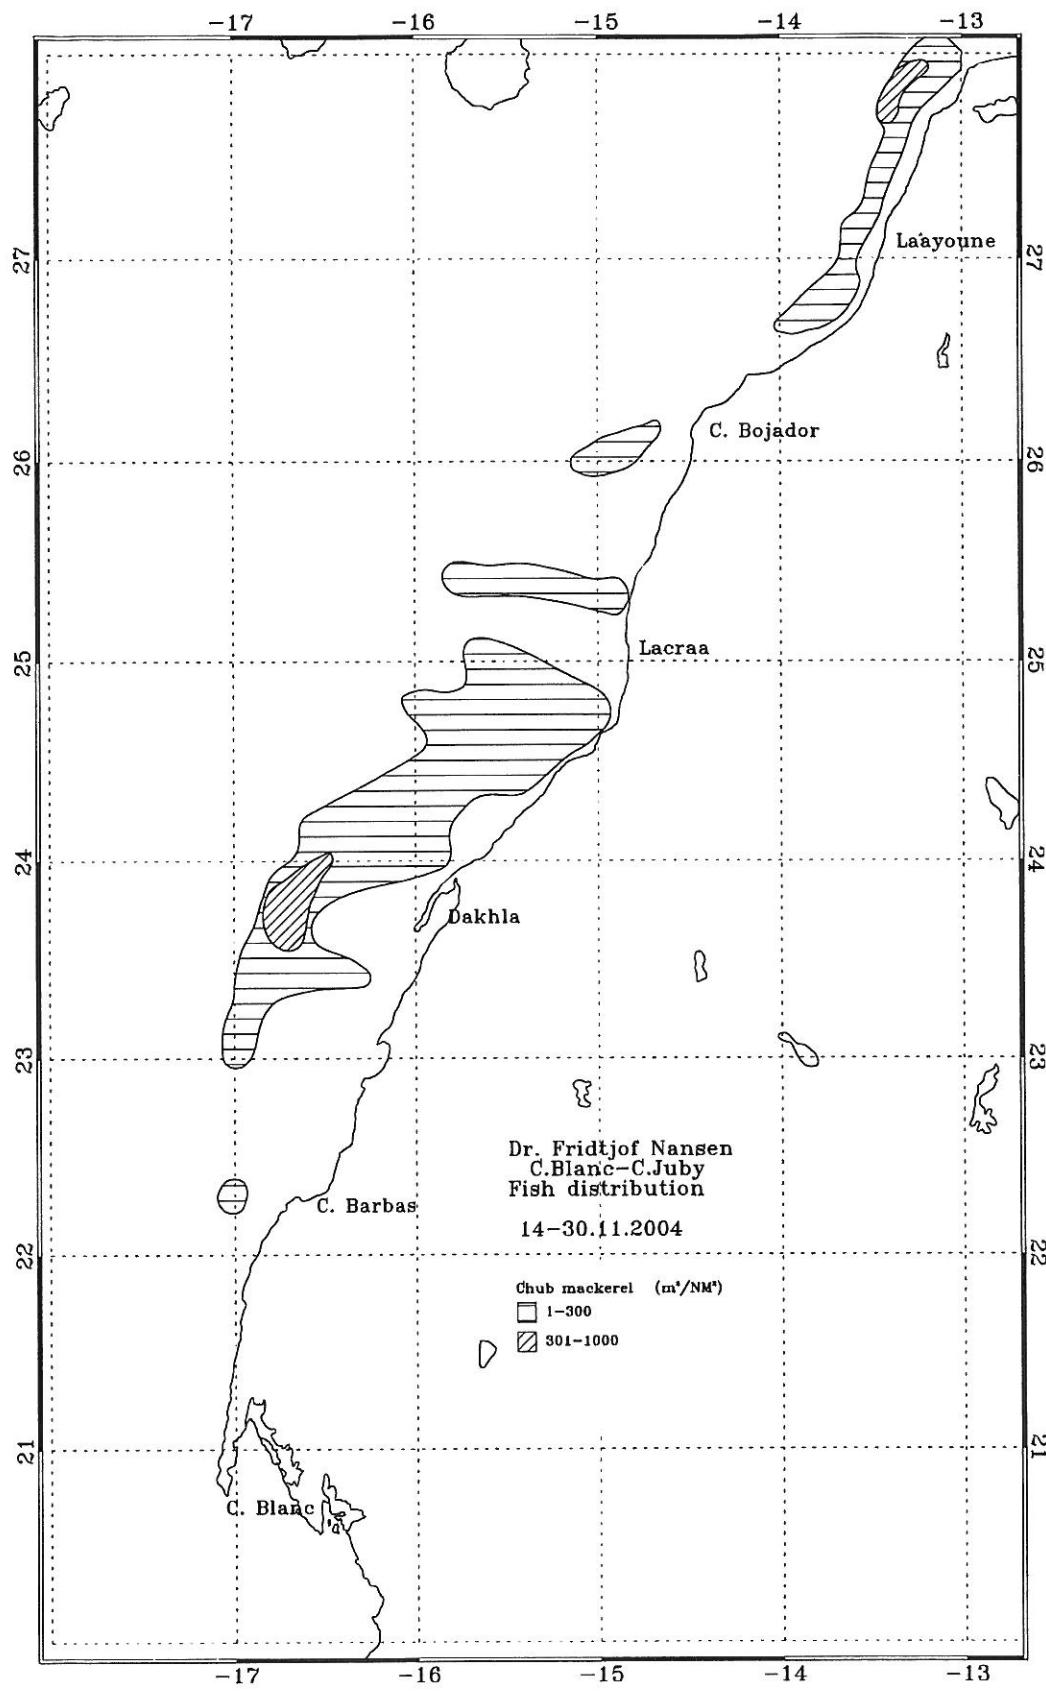

Figure 10. Distribution of chub mackerel, Cape Blanc to Cape Juby. Depth contours as in Fig. 1a.

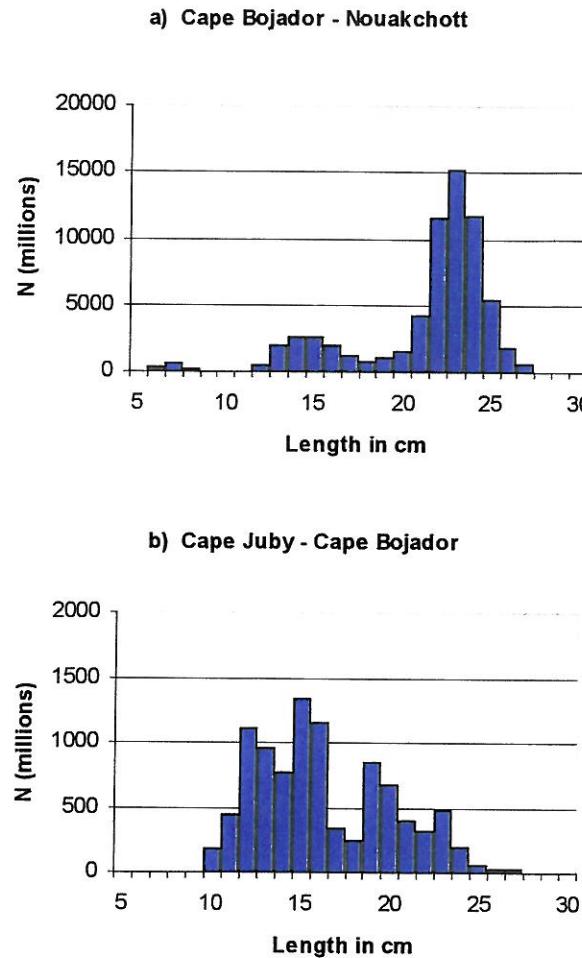

Figure 11. Length frequency distributions sardine Cape Timiris to Cape Juby.

### 2.3 Distribution of pelagic fish on the shelf from Cape Juby to Cape Cantin.

Sardine was recorded in the coastal area from Cape Juby to Cape Ghir, Figure 12. The highest densities of sardine were observed between Tan Tan and Sidi Ifni. Between Cape Ghir and Cape Sim no sardine were found. Patches with high densities were found between Cape Sim and Cape Cantin. The aggregations consist mainly of two young cohorts with modes around 15 and 18 cm, Figure 15.

Anchovy was mostly found in a few low-level patches, the densest near Sidi Ifni, Figure 13.

**Chub mackerel** was found all along the coast from Cape Juby to Cape Cantin, generally in low densities, Figure 14. Denser patches were found between Cape Juby and Tan Tan, near Sidi Ifni and on the outer shelf between Cape Sim and Safi.

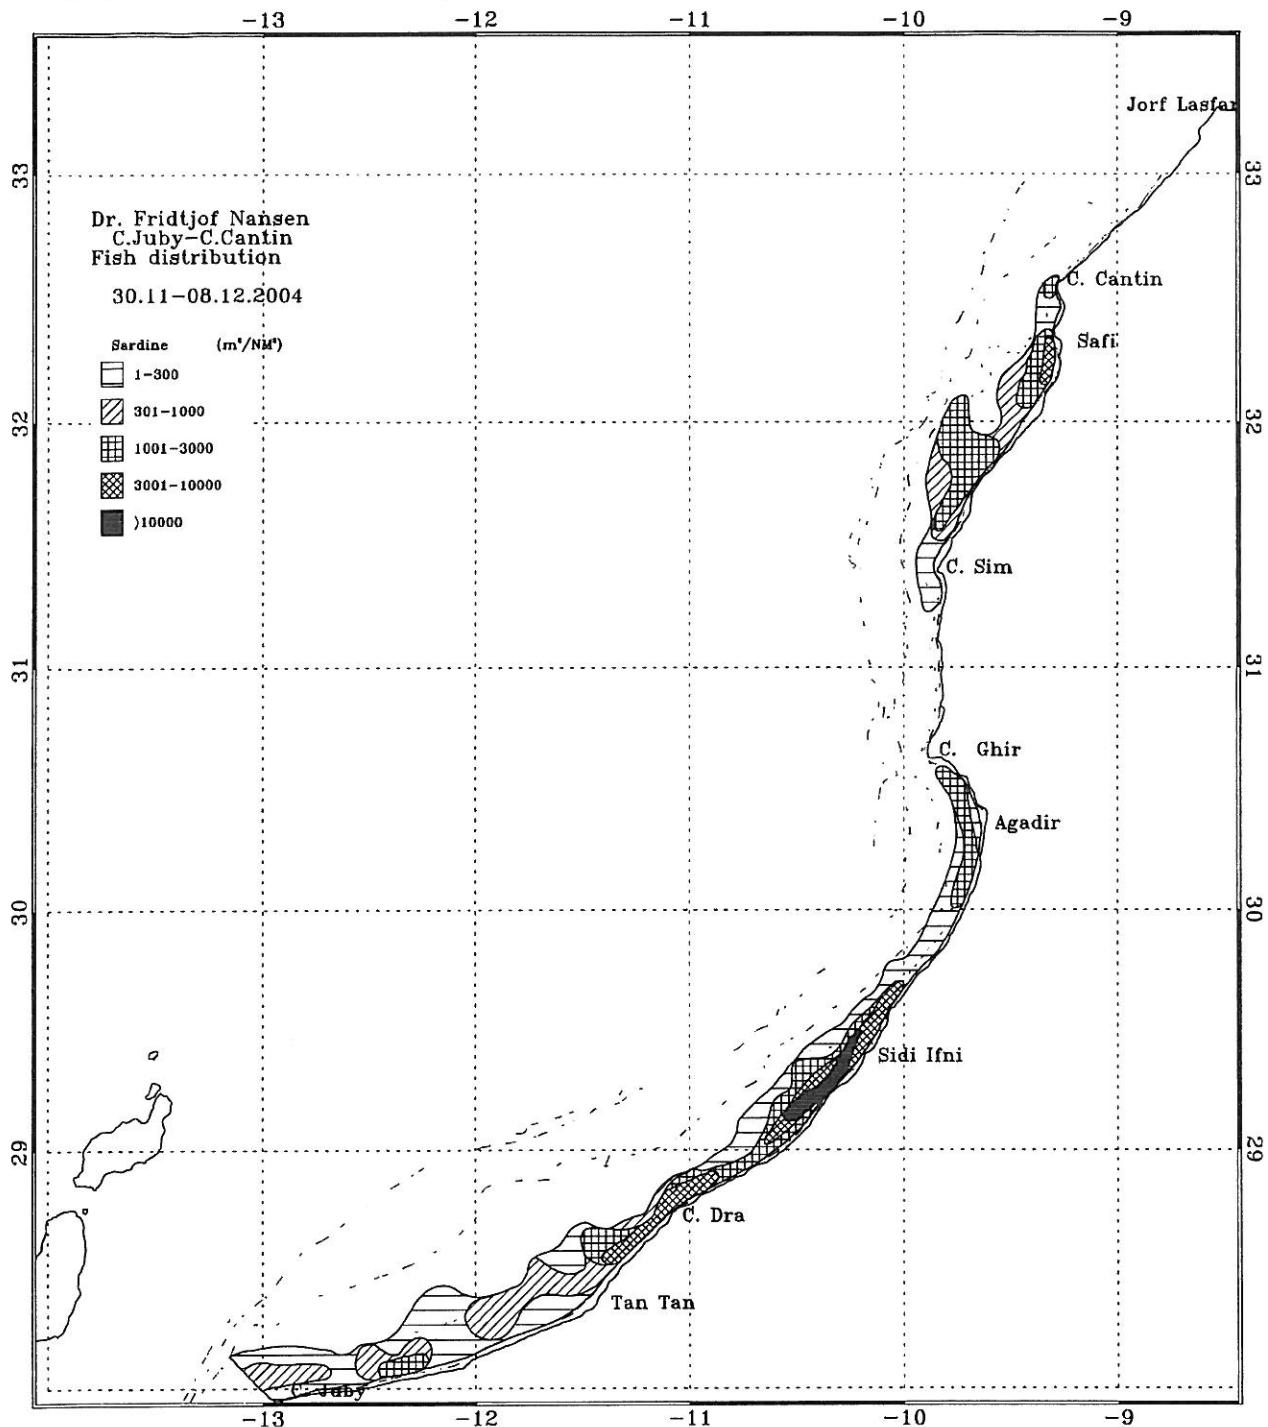

Figure 12. Distribution of sardine, Cape Juby to Cape Cantin. Depth contours as in Fig. 1a.

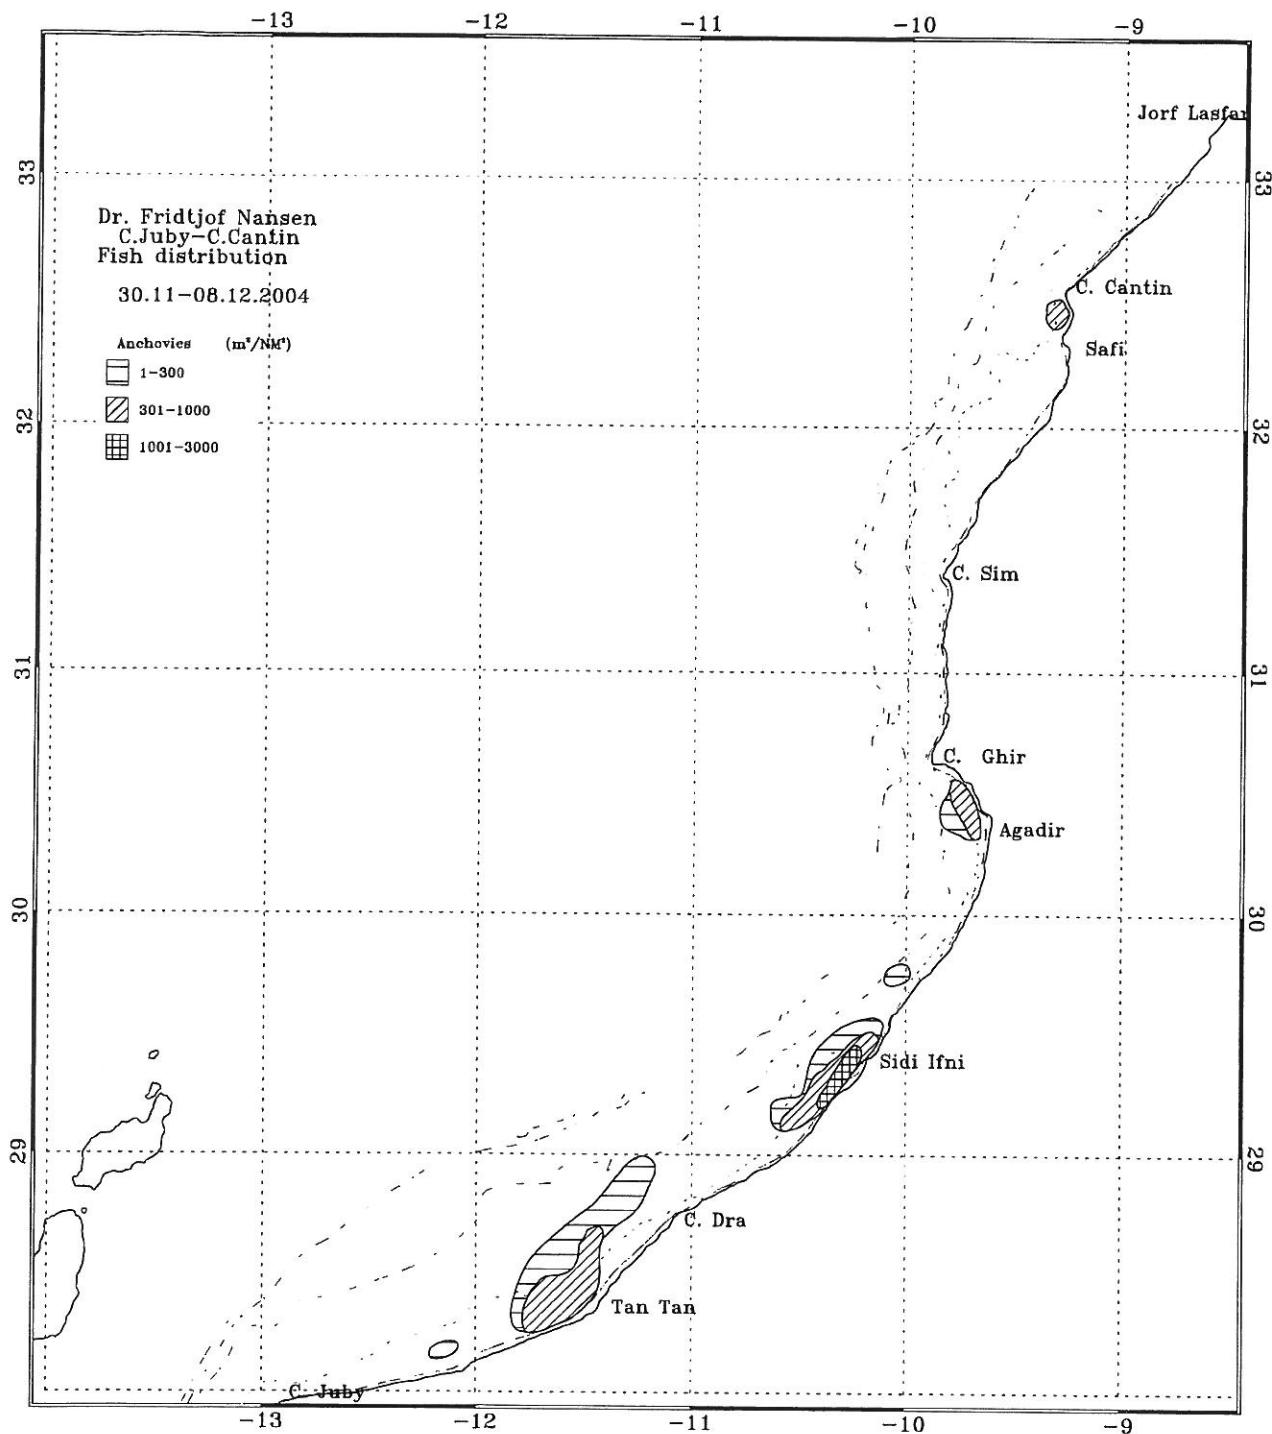

Figure 13. Distribution of anchovy, Cape Juby to Cape Cantin. Depth contours as in Fig. 1a.

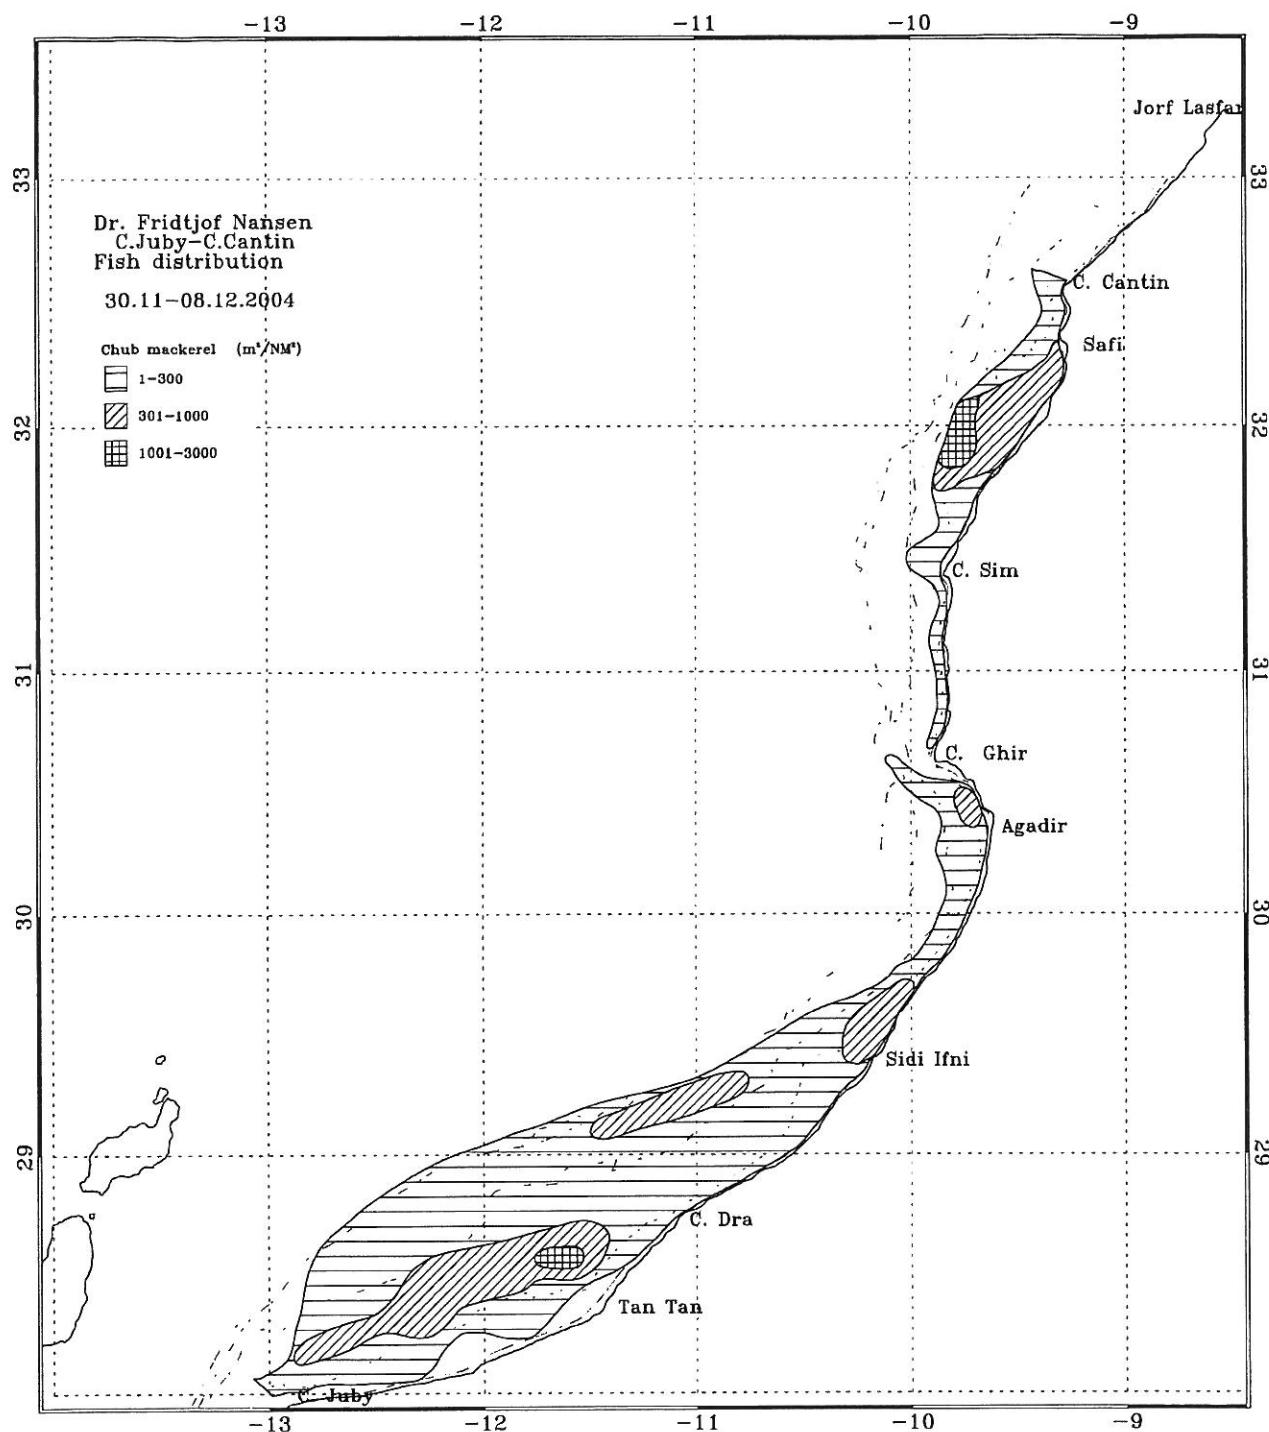

Figure 14. Distribution of chub mackerel, Cape Juby to Cape Cantin. Depth contours as in Fig. 1a.

Recordings of horse mackerel were very few and scattered.

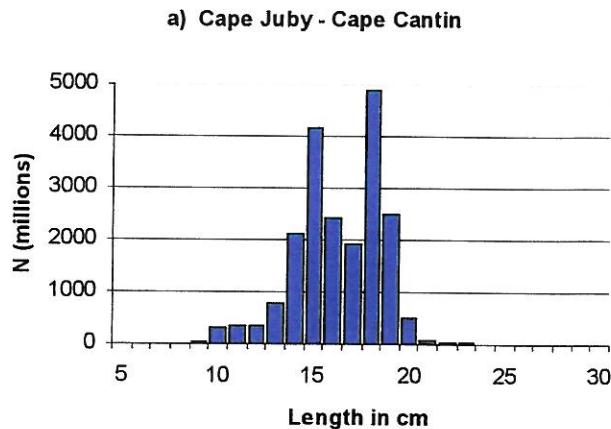

Figure 15. Length frequency distribution of sardine Cape Juby to Cape Cantin.

## 2.4 Biomass estimates

A summary on biomass estimates is given in Table 1 below. More detailed biomass estimates in number and weight by length groups are shown in Annex I.

### Cape Blanc – Cape Bojador

The **sardine** was estimated to 5.7 million tonnes, which is higher than the 4.4 million tonnes one year earlier, but similar to the estimate in June 2003. If the sardine in Mauritania in November is included, the biomass of the southern stock is estimated to 6.1 million tonnes. The length distribution is earlier shown in Figure 11. The major share of the fish in terms of biomass consists of older fish. Compared with earlier years, the development in the “adult” part of the stock (i.e. fish >19cm) is:

Survey	Thousand tonnes	Million fish
November-December 1996	4 600	47 400
November-December 1997	240	2 900
November-December 1998	340	3 400
November-December 1999	1 000	11 500
November-December 2000	1 260	13 200
May-June 2001*	1 975	22 500
November-December 2001	3 200	32 000
May-June 2002*	2 100	21 400
November-December 2002	3 700	35 500
June 2003*	5 580	59 300
November-December 2003*	4 370	43 600
November-December 2004*	5 720	51 900

\* Including sardine in Mauritania

The strong increase in the adult stock, which has been observed during the later years, seems now to have come to a halt. This may be an indication that the adult stock is close to the carrying capacity of the ecosystem. At present, the recruitment to the stock appears very low. The young fish (<20 cm), including the fish in Mauritanian waters, constitute only of about 14 billion fish, compared to 7 billion the previous year.

**Sardinella** was estimated to roughly 1.7 million tonnes of which 1.1 and 0.6 million are round and flat sardinella respectively, Annex I. The main part of the fish is located between Cape Blanc and Cape Barbas and seems to constitute most of the regional stock of round sardinella, but only 23% of the flat variety. In the preceding survey in Senegal and Mauritania 2.4 million tonnes of sardinella were estimated south of Cape Blanc, see Annex IV.

**Anchovies** were estimated to 43 thousand tonnes, while the previous year the very scattered recordings only made up 18 thousand tonnes, Annex I.

The two species of **horse mackerel** combined was estimated to 0.74 million tonnes (Annex I), of which roughly 160 thousand tonnes and 580 thousand tonnes were Atlantic and Cunene horse mackerel respectively. The corresponding figures last year were 300 and 850 thousand tonnes respectively. Young fish of Cunene horse mackerel (11-22 cm) are estimated to about 300 thousand tonnes and gives some growth potential to the stock. The species are also distributed south of Cape Blanc into Mauritania and Senegal and estimated to 160 thousand tonnes, Annex IV.

**Chub mackerel** were estimated to about 150 thousand tonnes, a reduction from the 320 thousand tonnes estimated last year, Annex I. It should be noted that the chub mackerel has a small swimming bladder, and thus low target strength (TS). In lack of measured target strength, the TS for sardine has been applied in the estimates, which will produce an underestimate estimate.

#### *Cape Bojador – Cape Juby*

Estimated **sardine** in this region is 430 thousand tonnes compared to 330 thousand tonnes last year, 220 thousand tonnes in 2002 and 330 thousand tonnes in 2001.

#### *Cape Juby – Cape Cantin*

The **sardine** is estimated to 840 thousand tonnes, about 180 thousand tonnes higher than the estimate one year earlier. The abundance in numbers is about 20 billion compared to the 18 billion in 2003. The main part of the biomass (94%) is made up of young fish less than 19 cm length, Annex I.

**Anchovies** were estimated to only 32 thousand tonnes, a considerable increase from the 8 thousand estimated a year earlier, and about the same as in 2002.

**Chub mackerel** estimates have been increasing gradually since 2000. The estimate this year is 340 thousand tonnes, while the estimates in 2003 and 2002 were 210 thousand tonnes and 20 thousand tonnes respectively. One should take note that these estimates should be treated as relative figures. The chub mackerel is probably considerable under-estimated due to the low and uncertain target strength of the species.

Table 1 Summary of biomass estimates of pelagic fish, thousand tonnes.

Region	Sardines	Round sardinella	Flat sardinella	Atlantic horse mackerel	Cunene horse mackerel	Chub mackerel	Anchovy

## CHAPTER 3 CONCLUDING REMARKS

---

Meteorological and hydrographic conditions during this survey indicated a prolonged summer condition, which climatologically would be more typical to late October/early November. Winds were generally calm and from variable directions, and surface waters appeared to be warmer than in the same period during the last survey years.

Figure 16 gives a general overview on the major aggregations of pelagic fish with rounded biomass figures. The biomass estimates are also summarised in Table 1.

The **sardine** in the southern region has normal distribution pattern with the adults off Dakhla and the juveniles and adults south of Cape Barbas. The biomass of sardine between Cape Blanc and Cape Bojador seems to have increased from 4.4 million tonnes in 2003 to 5.7 million tonnes during the last survey. The biomass has stayed on a high level, in the range 4-6 million tonnes, since 2002. 420 thousand tonnes of the present stock is juvenile fish. In addition 400 thousand tonnes of adult sardine is found in Mauritanian waters (one patch south off Cape Blanc and a smaller between Cape Timiris and Nouakchott. Sardine in the region Cape Bojador-Cape Juby is estimated to 430 thousands tonnes, about 100 thousand tonnes more than one year earlier. Further north, the stock between Cape Juby and Cape Cantin is estimated to 840 thousands tonnes, about 25% higher than last year. Recruitment seems to be normal. Most of the fish is of young size with good growth potential.

**Sardinellas** were mainly recorded in the Cape Blanc and Cape Barbas area, but were also found near Dakhla and south off Cape Bojador. The biomass was estimated to 1.1 million tonnes, ABOUT 40% of the entire regional stock.

**Anchovies** were only estimated to 80 thousand tonnes between Cape Blanc and Cape Cantin, and seem to be on a very low level.

**Horse mackerels** were forming dense aggregations from Cape Blanc to north off Cape Barbas and were else found in scattered patches in the whole survey area. The combined estimate of the two species of horse mackerel is 747 thousand tonnes of which 580 thousand tonnes is Cunene horse mackerel south of Cape Barbas. There is a high presence of juvenile fish. The Cunene horse mackerel seems to be growing in abundance lately.

**Chub mackerel** is on a relatively high level, about the same level as last year. The biomass index is 165 thousand between Cape Blanc and Cape Juby, and 340 thousand between Cape Juby and Cape Cantin,

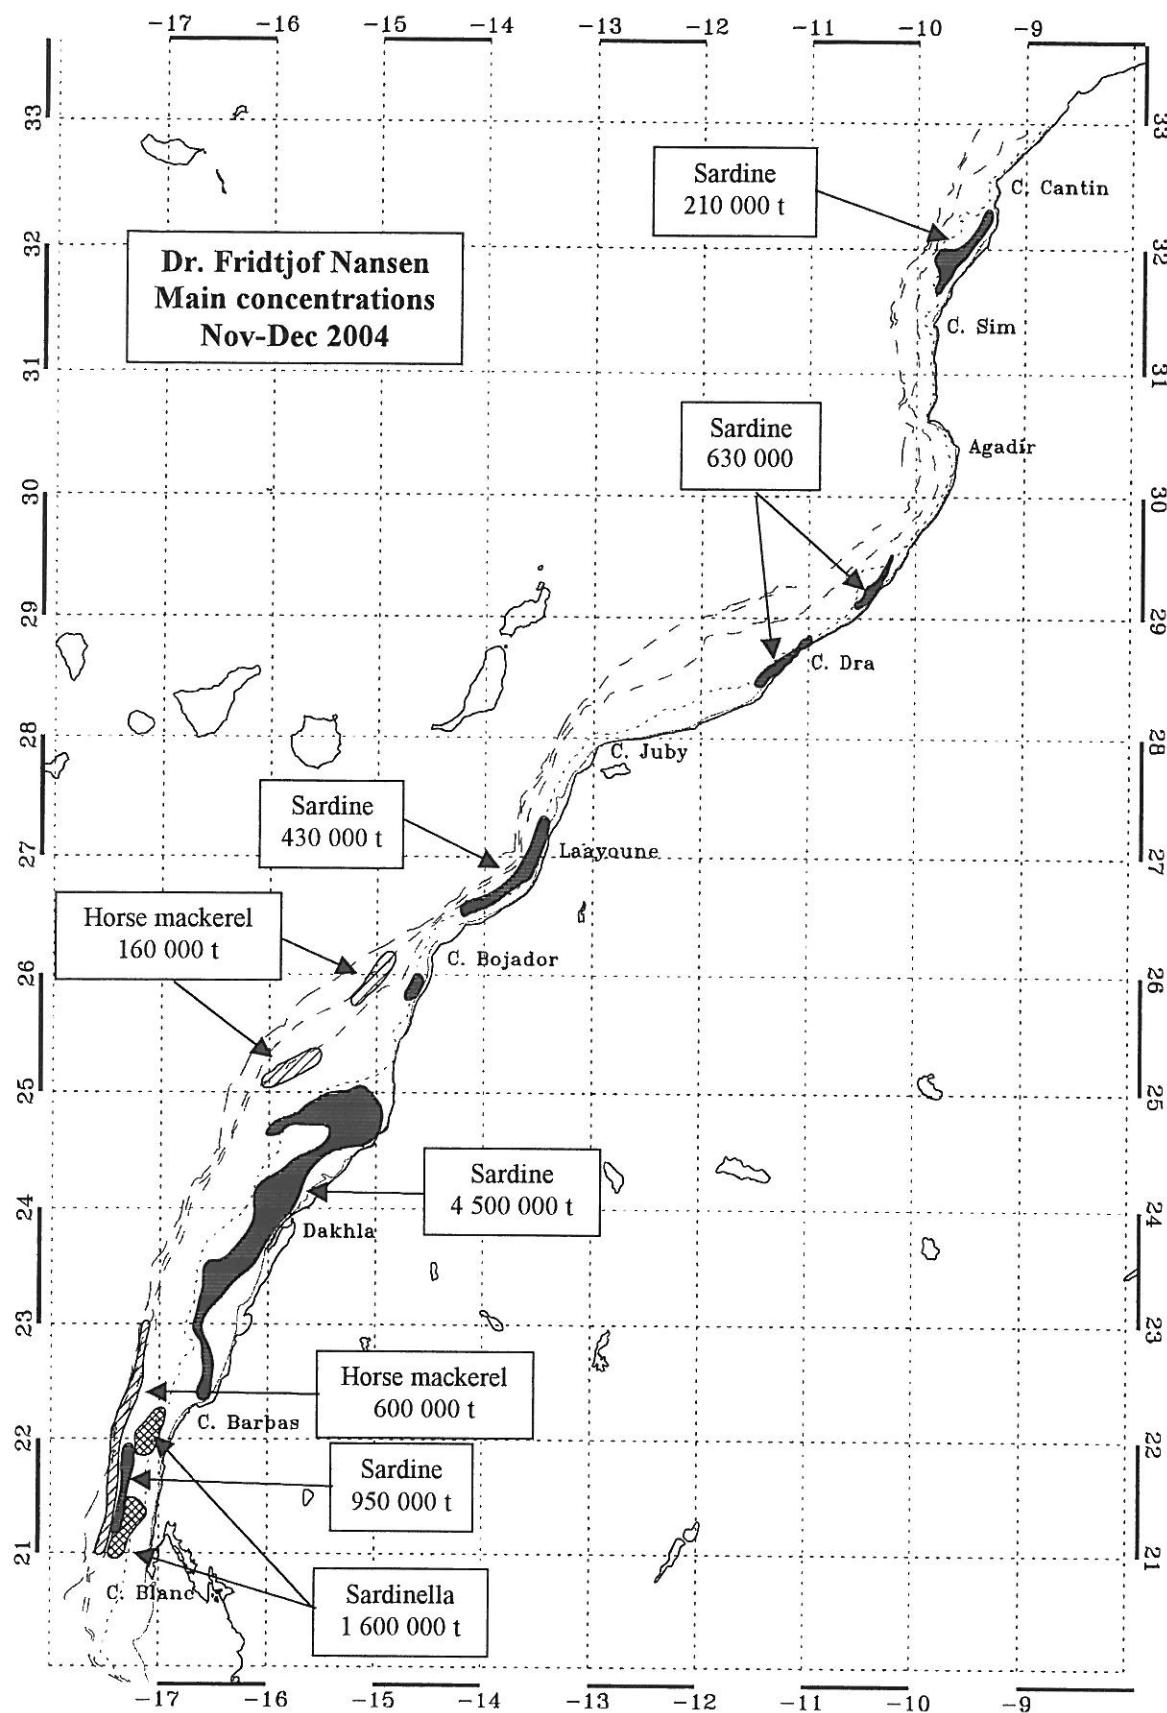

Figure 16. Map of the major pelagic fish concentrations with estimated abundance (tonnes), Cape Blanc to Cape Cantin.

### Trends 1995-2004, sardine

Figure 17 shows the biomass estimates of sardine compared with results from previous *Dr. Fridtjof Nansen* surveys. Figure 18 shows the biomass figures 1995-2004 by length classes. Both figures display that the stock between Cape Blanc and Cape Juby has now fully recovered from its sudden collapse in 1997. It is reasonable to include the recordings south of Cape Blanc as they belong to the same unit stock and most of the year stays north of Cape Blanc. The stock seems recently to fluctuate around 5 million tonnes, a figure also close to the maximum of the pre-1997 years. This level seems close to the carrying capacity of the system. The abundance of juveniles in the size range 13-18 cm is remarkably low in the last two surveys, in contrast to three years earlier.

Small fish, less than 20 cm, continue to dominate the central stock between Cape Juby and Safi. The level of the stock seems to have increased since November 2003.

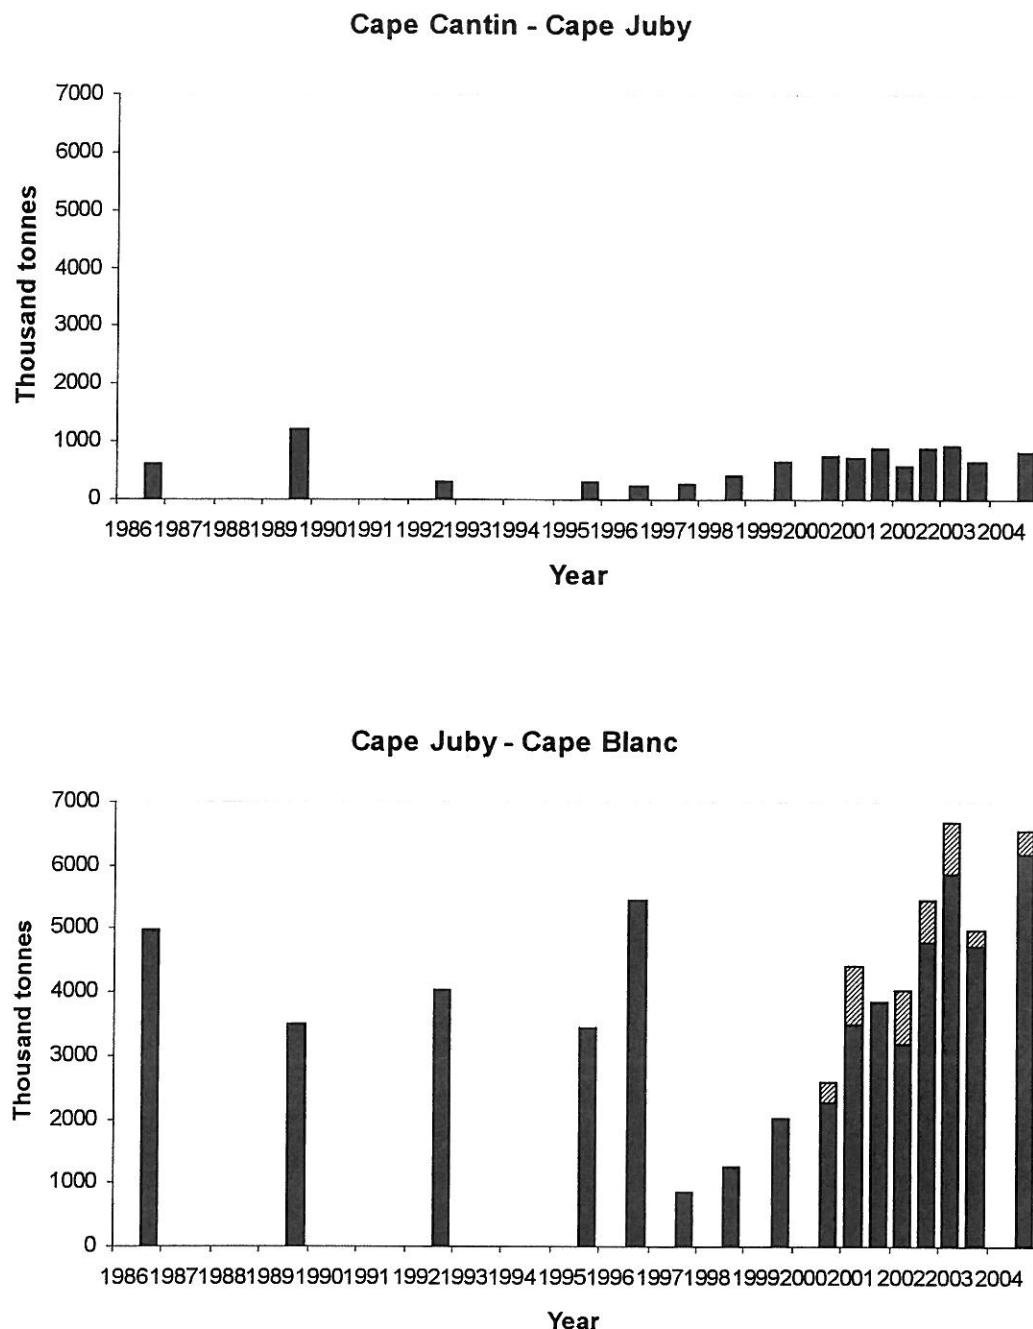

Figure 17. Sardine biomass estimates Cape Cantin-Cape Juby and Cape Juby-Cape Blanc. Sardine south off Cape Blanc hatched. *Dr. Fridtjof Nansen* 1986-2004.

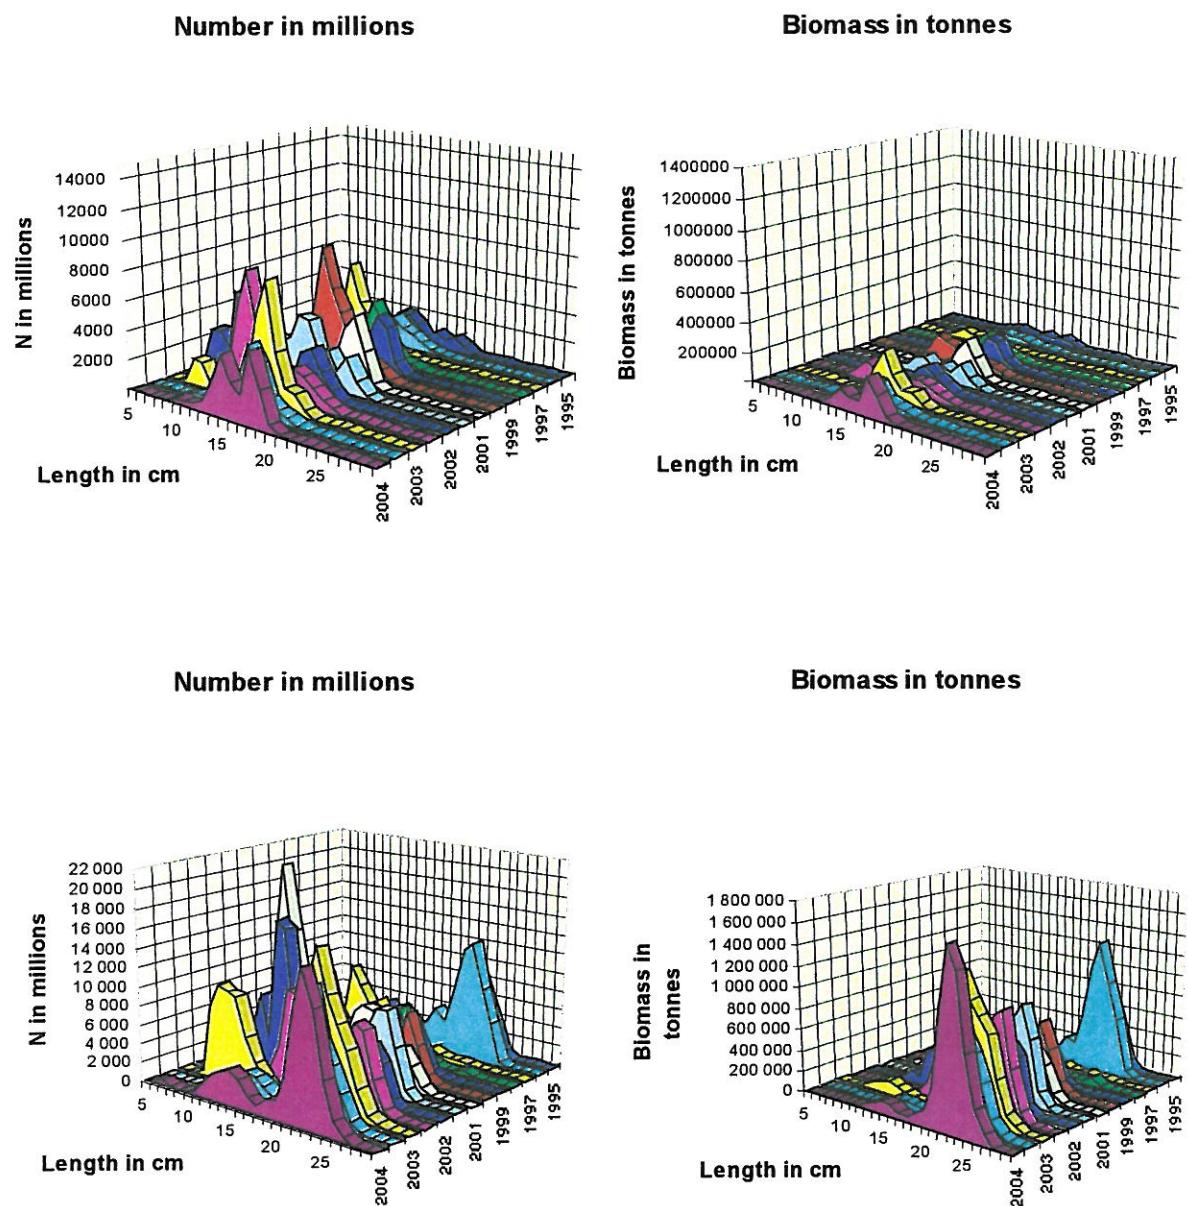

Figure 18. Numbers and biomass by length class, 1995-2004. Cape Juby - Cape Cantin (top) and Cape Blanc - Cape Juby (bottom).

### **Annex III Instruments and fishing gear used**

The Simrad EK-500, 38kHz scientific echosounder was used for abundance estimation during the survey, in addition data from the 18 kHz, 120 kHz and 200 kHz transducers were recorded for possible future multifrequency target identification. The Bergen Echo Integrator system (BEI) recorded the hydroacoustic data and was used to scrutinize the acoustic records, and to allocate integrator data to fish species. All raw data were stored to tape and brought back to IMR for storing.

The details of the settings of the echosounders were as follows:

#### **Transceiver 1 menu**

Transducer depth	5.5 m
Absorption coeff.	10 dB/km
Pulse length	medium (1ms)
Bandwidth	wide
Max power	2000 Watt
2-way beam angle	-21.0 dB
SV transducer gain	27.17dB
TS transducer gain	29.96
Angle sensitivity	21.9
3 dB beamwidth along.	7.3
3 dB beamwidth athw.	7.0
Alongship offset	0.05
Athwardship offset	0.04

#### **Transceiver 2 menu**

Transducer depth	5.5 m
Absorption coeff.	38 dB/km
Pulse length	long (1ms)
Bandwidth	narrow
Max power	1000 Watt
2-way beam angle	-20.6 dB
SV transducer gain	25.96B
TS transducer gain	25.95dB
Angle sensitivity	21.0
3 dB beamwidth along.	7.4
3 dB beamwidth athw.	7.2
Alongship offset	0.24
Athwardship offset	0.04

**Transceiver 3 menu**

Transducer depth	5.5 m
Absorption coeff.	3 dB/km
Pulse length	short (0.7ms)
Bandwidth	wide
Max power	2000 Watt
2-way beam angle	-17.2 dB
SV transducer gain	23.75dB
TS transducer gain	23.36B
Angle sensitivity	13.9
3 dB beamwidth along.	10.8
3 dB beamwidth athw.	10.8
Alongship offset	0.06
Athwardship offset	-004

**Transceiver 4 menu**

Transducer depth	5.5 m
Absorption coeff.	53 dB/km
Pulse length	Long
Bandwidth	Narrow
Max power	1000 Watt
2-way beam angle	-20.5 dB
SV transducer gain	24.18 dB
TS transducer gain	24.80 dB
Angle sensitivity	0.0
3 dB beamwidth along.	0.0°
3 dB beamwidth athw.	0.0°
Alongship offset	-0.00°
Athwardship offset	0.00°

Minimum level	-40 dB
---------------	--------

**Calibration**

A calibration of the acoustic equipment was conducted during the survey in Angola in August 2004.

### Fishing gear

The vessel has three different sized four-panel 'Åkrahamn' pelagic trawls and one 'Gisund super bottom trawl'. The two smallest pelagic trawls and the demersal trawl were used during the survey. The smallest pelagic trawl has 10-12 m vertical opening under normal operation, whereas the intermediate sized trawl has 15-18 m opening.

The bottom trawl has a 31 m headline and a 47 m footrope fitted with a 12" rubber bobbins gear. The codend has 20 mm meshes, and has an inner net with 10 mm mesh size. The vertical opening is about 5.5 m. The distance between the wing tips is about 18 m during towing. The sweeps are 40 m long. The trawl doors are 'Thyborøen' combi, 8 m<sup>2</sup> and weigh 2000 kg. The door spreading is about 45 m when using restraining rope. Trawling was conducted for species identification only and no restraining rope was therefore used during the survey.

The SCANMAR system was used during all trawl hauls. This equipment consists of sensors, a hydrophone, a receiver, a display unit and a battery charger. Communication between sensors and ship is based on acoustic transmission. The doors are fitted with sensors to provide information on their distance and a height sensor is fitted on the bottom trawl to measure the trawl opening and provide information on clearance and bottom contact.

The pelagic trawls are equipped with a trawl eye that provides information about the trawl opening and the distance of the footrope to the bottom. A pressure sensor is used to show the depth on the headline.
