INIP, Luanda  
Angola

## THE EAF-NANSEN PROJECT

FAO started the implementation of the project “Strengthening the Knowledge Base for and Implementing an Ecosystem Approach to Marine Fisheries in Developing Countries (EAF-Nansen GCP/INT/003/NOR)” in December 2006 with funding from the Norwegian Agency for Development Cooperation (Norad). The EAF-Nansen project is a follow-up to earlier projects/programmes in a partnership involving FAO, Norad and the Institute of Marine Research (IMR), Bergen, Norway on assessment and management of marine fishery resources in developing countries. The project works in partnership with governments and also GEF-supported Large Marine Ecosystem (LME) projects and other projects that have the potential to contribute to some components of the EAF-Nansen project.

The programme has previously conducted the following demersal surveys in the area:

January 1985	-	June 1986	(6 surveys)
January 1989	-	December 1989	(3 surveys)
May 1991	-	September 1992	(3 surveys)
January 1994	-	March 2011	(19 surveys)

## **CHAPTER 1 INTRODUCTION**

---

### **1.1 Objectives**

The objectives of the cruise had been previously discussed and agreed upon by the responsible of the Demersal Programme of the Instituto Nacional de Investigação Pesqueira (INIP) of Angola, and the responsible from the Institute of Marine Research (IMR), Norway, for the Angolan Demersal Programme, and were the following:

- To map and describe the distribution, composition and abundance of the main demersal species, with emphasis on seabreams (Sparidae), croakers (Sciaenidae), grunts (Haemulidae), groupers (Serranidae), hakes (Merlucciidae), cephalopods and shrimps (*Parapenaeus longirostris* and *Aristeus varidens*) on the Angolan shelf and slope (down to 800 m), from Benguela (12°35'S) to Congo River (06°00'S) using bottom trawl and the swept-area method. Due to time constraints, it had been agreed to cover the southern region from Tombua (15°40'S) to Cunene River (17°14'S) at the end of the pelagic survey in July-August.
- To collect biological data such as length, weight, sex and maturity stage of *Dentex macrophthalmus*, *D. angolensis*, *Pagellus bellottii*, *Pseudotolithus senegalensis*, *Umbrina canariensis*, *Merluccius polli*, *Brachydeuterus auritus*, *A. varidens*, *P. longirostris*, *Chaceon maritae*, *Panulirus regius* and cephalopods.
- To collect stomach contents for *D. angolensis*, *Merluccius polli*, *P. senegalensis*, *U. canariensis* and *B. auritus*, for subsequent analyses in the INIP Lab.
- To monitor the general hydrographical conditions using thermosalinograph and CTD-sonde on trawl station and map the temperature, salinity and oxygen.
- To carry out four monitoring lines (Namibe, Lobito, Palmerinhos and Congo River mouth) using INIP's new standard hydrographical profiles for collection of temperature, salinity and oxygen, water nutrients, phytoplankton and zooplankton.

### **1.2 Participation**

The scientific staff consisted of:

From INIP, Angola (22.03-09.04): Silvi Nsiangango (Local Cruise Leader), Virgílio Estévão, Fátima Delicado, Mário Fortunato, Pedro Panzo, David Kissungo, Euzébio dos Santos, Bomba Bazika Sangolay and Paulo Coelho.

From IMR, Norway: (20.03-09.04) Sigbjørn Mehl (Cruise Leader), Inês Dias Bernardes,

Jan Frode Wilhelmsen and Terje Svoren.

### 1.3 Narrative

R/V “Dr Fridtjof Nansen” departed from Pointe Noire, Congo, at 1500 20<sup>th</sup> March 2011 and made a stop to take onboard fuel before steaming to Luanda for change of personnel. The vessel called port in Luanda at 1030 22<sup>nd</sup> March and departed shortly before noon 23<sup>rd</sup> March.

The survey started with trawl and hydrographical stations in the central region at 1300 the same day. A standard geographical allocation of the trawl stations, to be taken during the Angolan demersal trawl surveys, was implemented in 2003. The station positions in the central and northern regions have been similar in the 2002-2010 surveys. Two monitoring lines, one off Pta. das Palmerinhas and another off Lobito were carried out in this region; the first monitoring line had 7 stations while the latter had 8 stations. On each station of the monitoring line, zooplankton was sampled with a multinet and phytoplankton with CTD bottles.

The survey of the central region was completed in the early evening 29<sup>th</sup> March and the vessel steamed to the northern region, where the survey continued at noon 30<sup>th</sup> March. In this region one Angolan monitoring line was done at the Congo River (Pta. da Moita Seca). The survey of the northern region was completed shortly after noon 7<sup>th</sup> April and R/V “Dr. Fridtjof Nansen” called port in Luanda at noon 8<sup>th</sup> April.

The monitoring lines were carried out in accordance with the new standards for monitoring lines run by INIP, see Annex IX. These transects were selected according to the regional requirements as the Angolan monitoring lines (Namibe, Lobito, Ponta das Palmerinhas and the Congo River). They end further off-shore and the distance between the stations is longer than the former standard “Nansen” transects. The depth intervals for plankton sampling were introduced in 2009 and repeated this year.

Due to time constraints, the southern region was not covered during the 2011 survey. In the central region the number of trawl stations was reduced by approximately 30% and the CTD sonde was not used in all trawl stations. Only at bottom trawl stations in deeper waters, CTD profiles were taken to complement shallower stations taken during the preceding pelagic survey from 9 to 15 March. In addition two “CTD transects” were done at bottom trawl stations off Cabo Sao Braz and Pta. do Morro. In the northern region the number of trawl stations was reduced by approximately 15%. CTD profiles were taken at about every 2<sup>nd</sup> or 3<sup>rd</sup> bottom trawl station. In the Northern region, one “CTD transect” was done at bottom trawl stations off Ambriz. Due to problems with the sea water pump, the thermosalinograph was not run in large parts of the northern region.

## CHAPTER 2 METHODS

---

### 2.1 Survey effort

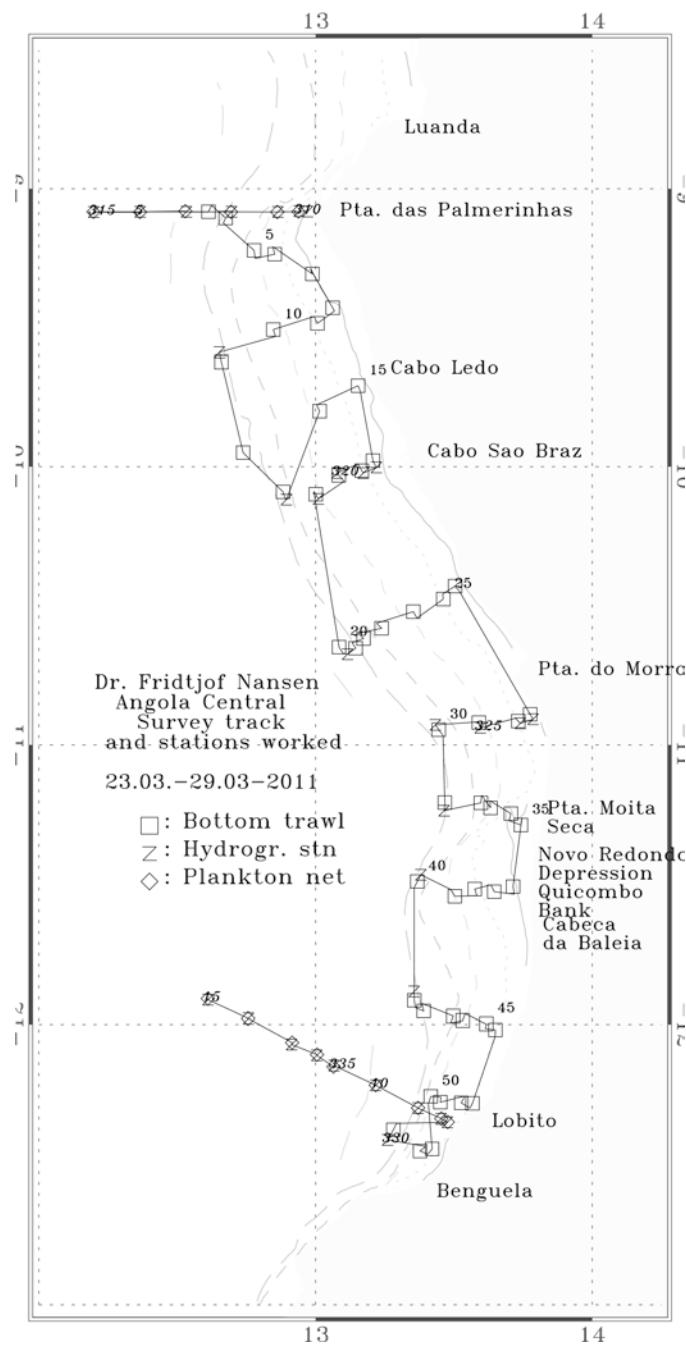

Table 2.1 presents the surveyed area by depth strata, allocation of trawl stations, total number of successful swept-area hauls, number of hauls failed, number of CTD stations, and the distance surveyed. The table also shows the allocation of effort relative to the stratum size as percentage hauls versus percentage area, by depth, region and total area. The overall average coverage was 1 valid trawl station per 110 square nautical miles (NM<sup>2</sup>). Figures 2.1-2.2 show the cruise tracks in the central and northern regions, respectively, and the locations of bottom trawl, plankton and hydrographical stations.

**Table 2.1** Survey design and effort for the 2011 demersal survey. Size of the survey area by depth stratum, allocation of trawl stations, proportion of stations relative to stratum size, total number of successful swept-area hauls, number of hauls failed, number of CTD stations, and the distance surveyed, divided in to: central region (Benguela to Ponta das Palmerinhas) and northern region (Ponta das Palmerinhas to Congo River).

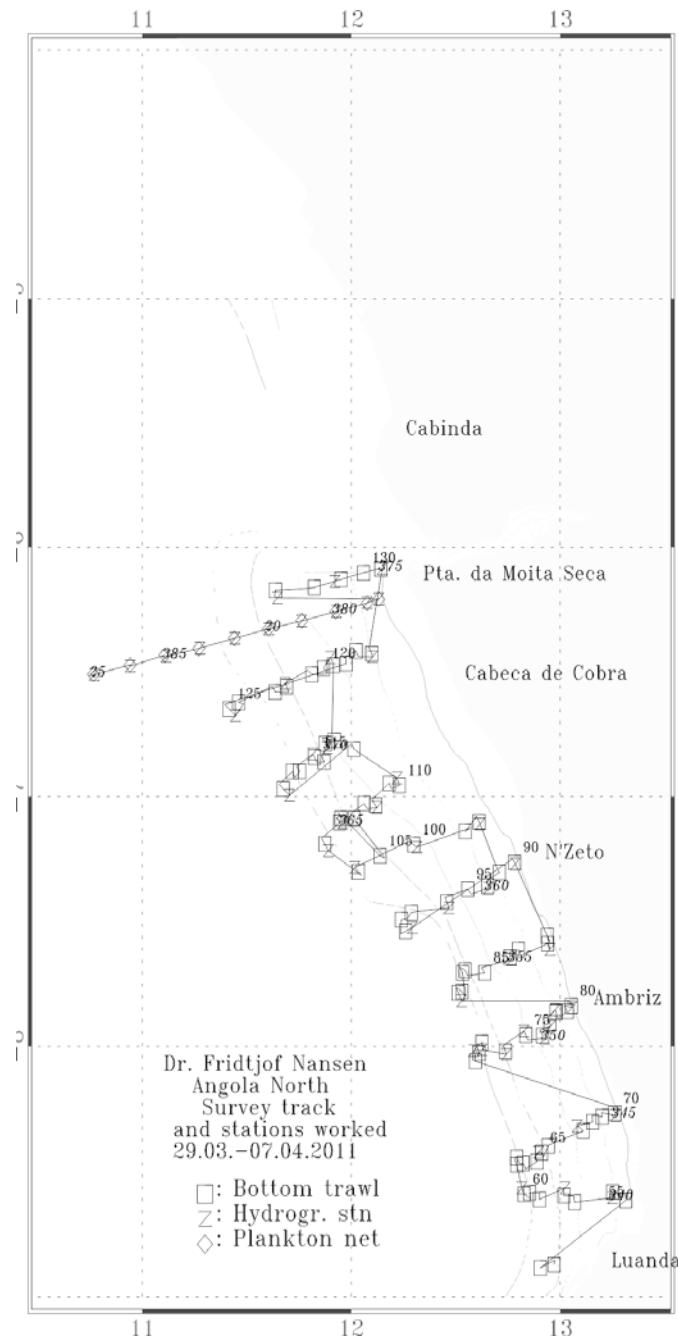

Region	Depth strata (m)										Valid	Failures	CTD	Distance (NM)
	20-50	50-100	100-200	200-300	300-400	400-500	500-600	600-700	700-800

%hauls	16.0	22.2	21.0	8.6	4.9	7.4	7.4	4.9	7.4					
<b>Grand total</b>														
Area (NM <sup>2</sup> )	2447	3555	3379	1008	922	788	755	676	1059	<b>14581</b>				
# hauls (BT)	24	33	26	9	7	8	10	4	10	<b>131</b>	2	<b>110</b>	<b>1941</b>	
%area	17.9	25.1	24	6.7	6	5	4.8	4.1	6.4					
%hauls	18.3	25.2	19.8	6.9	5.3	6.1	7.6	3.1	7.6		<b>Total hauls: 133</b>			

A stratified semi-random survey design was used with depth and area as stratifying variables. Trawling was carried out along transects perpendicular to the coast (Figures 2.1-2.2), and the allocation of trawl stations was proportional to stratum size. Trawling shallower than 300 m was mainly done during daytime and deeper than 300 m during dark hours. Adjustments to the planned design occurred when unsuitable bottom conditions were found or in non-accessible areas with oil exploitation, namely in the northern region.

Based on a decision made in 2003 it was decided that the trawl positions of the 2002 demersal survey should be used as the standard for future surveys in the central and northern regions, as the survey had a good coverage of these regions. Therefore, the station positions and effort have been similar during the 2002-2010 surveys in the central and northern regions (see Annex VIII). As mentioned, due to time constraints the southern region was not covered during the 2011 survey. In the regions covered the number of trawl stations was reduced, being the reduction around 29% in the central region and 15% in the northern region.

**Figure 2.1** Angola central: Benguela - Ponta das Palmerinhas. Course track with trawl, hydrographic, plankton stations and hydrographical transects. Depth contours at 20, 50, 100, 200 and 500 m.

**Figure 2.2** Angola north: Ponta das Palmerinhas - Congo River. Course track with trawl, hydrographic, plankton stations and hydrographical transects.. Depth contours at 20, 50, 100, 200 and 500 m.

## **2.2 Meteorological and hydrographical sampling**

A Seabird 911+ CTD probe was used to obtain vertical profiles of temperature, salinity and oxygen. Real time plotting and logging was done with the customised Seabird Seasave software installed on a PC. Profile data were logged down to a few meters above the bottom. A Chelsea fluorometer of the type Mk III Aquatrack was also attached to the CTD. It measures chlorophyll *a*, in microgram per litre, with an uncertainty of 3%. Factory slope and offset was 0.921 and -0.02.

Water samples for sensor calibration of oxygen were taken at the surface (4-5 m) and above the bottom on the Lobito and Congo River monitoring lines. However, the results of the analyses were biased and could not be used for correction of oxygen values. The salinity sensor has shown to be stable, and no calibration was conducted during the survey.

A SBE 21 Seacat thermosalinograph was running routinely during the survey, obtaining samples of sea surface salinity, relative temperature and fluorescence (5 m depth) every 10 seconds. An attached in-line Turner Design SCUFA Fluorometer continuously measured Chlorophyll *a* levels [RFU] at 5 m below the sea surface during the entire cruise. Due to problems with the sea water pump the thermosalinograph could not run in most of the northern region.

Meteorological observations including wind direction and speed, air temperature, global radiation and sea surface temperature (SST) were automatically logged using a WIMDA meteorological station. These observations were averaged by every nautical mile distance sailed.

A vessel-mounted Acoustic Doppler Current Profiler (VMADCP) from RD Instruments logged the current profiles continuously, and was set to ping synchronously with the echo sounders. The frequency of the VMADCP is 150 kHz, and data were averaged and stored in 4 m vertical bins in shallow water to approximately 400 m bottom depth and 8 m bins deeper than this.

## **2.3 Fish sampling**

### **Sampling gear**

A “Gisund Super” bottom trawl with a headline height of about 4.5 m was used during the survey, and the doors were of the “Thyborøn” combi type. The distance between the wings was about 21 m during deployment, at a speed of 3 NM h<sup>-1</sup>. These settings have been standard on all swept area surveys with R/V “Dr. Fridtjof Nansen”. A detailed description of the fishing gear is given in Annex VII.

As in previous surveys, except during the 2002 survey, a 44 m long tickler chain was attached to the footrope on depths of more than 300 m in order to catch more of the bottom dwelling deep-water shrimps. During all tows deeper than 80 m, a 9 m long constraining rope was attached between the warps 120 m in front of the trawl doors. This kept a constant distance between the doors of about 50 m during the trawling. In shallow stations with depths of less than 80 m, the door-to-door distance could show bigger variations, depending on bottom type and currents.

Trawl duration was standardized to 30 minutes; start time is controlled by using a "SCANMAR" sensor to detect the landing of the trawl on the bottom, and the stop-time is defined as the time when the wires start to haul the net. In some cases the towing was interrupted before 30 minutes either due to poor bottom conditions or too high catches of fish indicated by the installed catch sensors. If the stations were not trusted to reflect the density of fish on the bottom they were recorded as invalid in the Nansis database, and thus not considered for biomass estimates. Table 2.1 shows the numbers of valid and invalid stations.

### **Sampling the catches**

Catches were sampled for species composition by weight and numbers. The total body length of the fish (cm) was measured to the nearest 1 cm below, the carapace length of shrimps and carapace width of crabs to 1 mm below and the mantle length of squids to 1 cm below. The records of fishing stations, in numbers and weight, are presented in Annex I. For some commercially important species, pooled length frequency distributions, in which individual samples are raised to total catch, are shown by area in Annex II. The catch data, from each station, is logged into Nansis software after the sampling is complete. All the data introduced is quality controlled during the survey.

#### *Acoustic sampling*

Acoustic recordings were carried out, throughout the entire cruise, using a SIMRAD ER60 echo sounder at four frequencies: 18, 38, 120 and 200 kHz. Acoustic data were not processed on board, but all data were stored to files. A detailed description of the acoustic settings is given in Annex VII.

## **2.4 Plankton sampling**

### **Zooplankton**

The sampling was conducted by an "HYDROBIOS Multinet" with 5 nets, at the monitoring lines. The nets (180 µm) were remotely opened from the bridge of the vessel. The depth intervals covered in 2011 were the same as established in 2009: 200-100 m, 100 -75 m, 75-50 m, 50-25 m and from 25 m to the surface. In stations shallower than 25 m, the sample was taken from the bottom and up to the surface. A "SCANMAR" depth sensor gave real-time information of the depth and a flow meter inside the net was used to estimate the sampling volume. The zooplankton samples were preserved in 4% formalin to be taken to the INIP for further analysis.

### *Phytoplankton*

Phytoplankton samples were taken at each CTD station of the monitoring lines at five different standard depths, as defined in 2009: 5 m, 15 m, 25 m, 50 m and 75 m. The samples were preserved in 4% formalin and taken for further analysis at INIP.

## **2.5 Areas, depth strata and calculations**

Table 2.1 shows the areas, in NM<sup>2</sup>, for the central region (Benguela - Ponta das Palmerinhas: S12°40'-S09°00') and the northern region (Ponta das Palmerinhas - Congo River: S09°00'-S06°00') by depth strata. These strata are used to calculate the swept-area biomass estimates. All valid stations are treated as representative for the relevant depth intervals where the species or group of species were caught.

All equations used for the calculations are given in Annex IV. The effective fishing width of the trawl gear used by R/V “Dr Fridtjof Nansen” is considered to be 18.5 m. The effective fishing area is the product of the fishing width multiplied by the towing distance measured by the GPS. It is assumed that all fish within the trawling path are caught, which gives a catchability coefficient ( $q$ ), *i.e.* the fraction of the fish encountered by the trawl that was actually caught, equal to 1. The catchability coefficient is seldom known, but because the coefficient is assumed to be constant between surveys, the swept-area estimates will reflect any change in population abundances between surveys.

The survey design and effort, previous to 2002, were inconsistent, and made difficult any comparison between surveys. Therefore, it was discussed and agreed upon by the responsible of the Demersal Programme of the INIP, and the responsible for the Angolan Demersal Programme at the Institute of Marine Research, Norway that all biomass estimates since 1985 should be calculated in a standardized procedure. Data from the “Nansis” database were exported to flat ASCII text files. The software R 2.2.1<sup>⊗</sup> was used to calculate stratified density estimates sorted by survey and stratified by depth and latitude. Biomass estimates by species or species groups were obtained from a stratified mean density estimator using the equations in Annex IV.

---

<sup>⊗</sup> R Development Core Team (2005). R: A language and environment for statistical computing. R Foundation for Statistical Computing, Vienna, Austria. ISBN 3-900051-07-0, URL <http://www.R-project.org>.

## **CHAPTER 3 OCEANOGRAPHIC CONDITIONS**

---

### **3.1 Surface distribution**

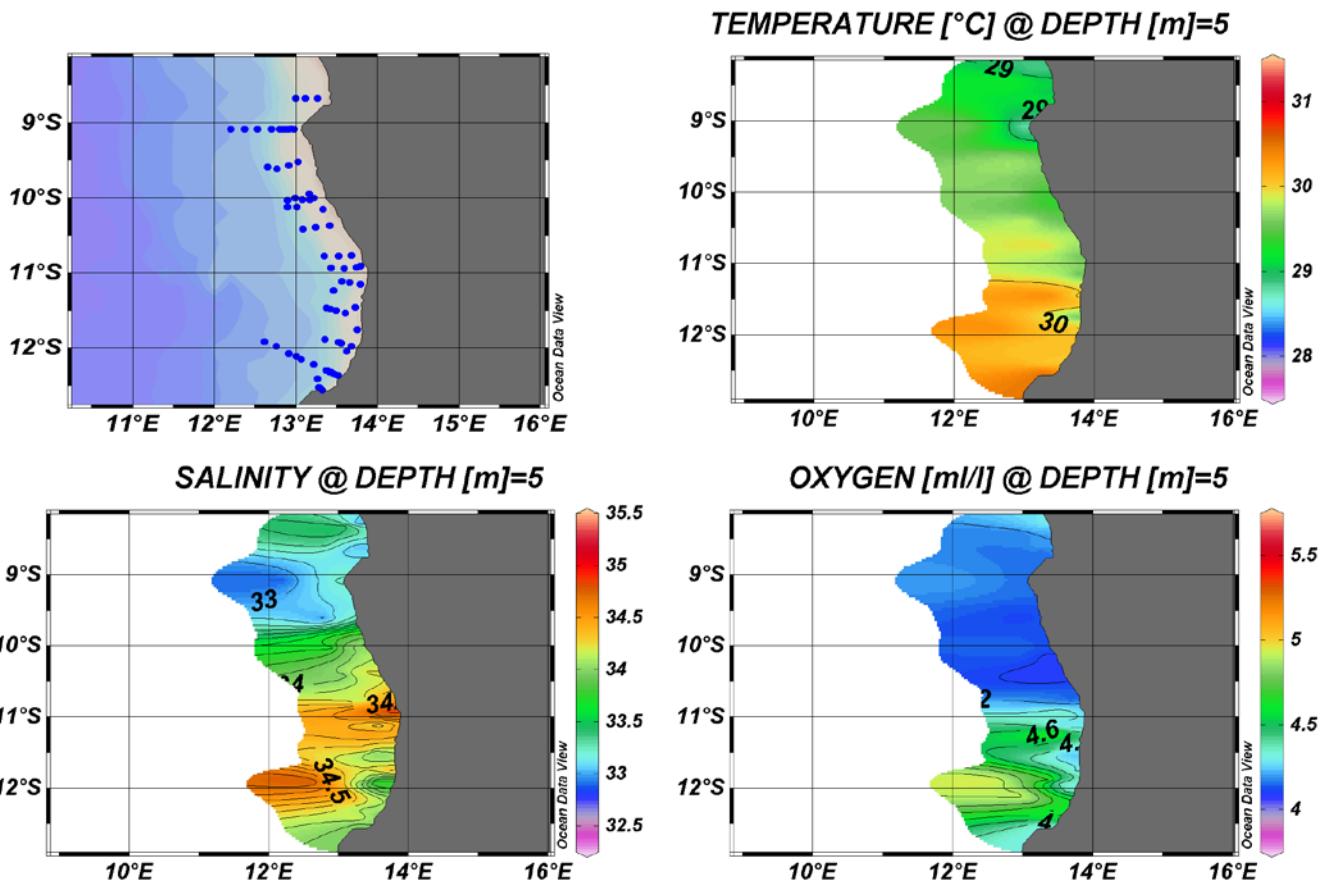

The salient feature of the hydrographical conditions in Angolan waters between December and March is the drop in the salinity at the surface, associated to the seasonal rise in the precipitation over the continent and consequent increase in the discharge of freshwater carried to the ocean by the Congo River and by other rivers along the Angolan coast. The regular demersal surveys carried out by R/V “Dr. Fridtjof Nansen” in March are coincident with the late phase of the wet season and, typically, it is observed low salinity in the surface waters in the shelf off the northern and central Angola regions.

#### **Central Region**

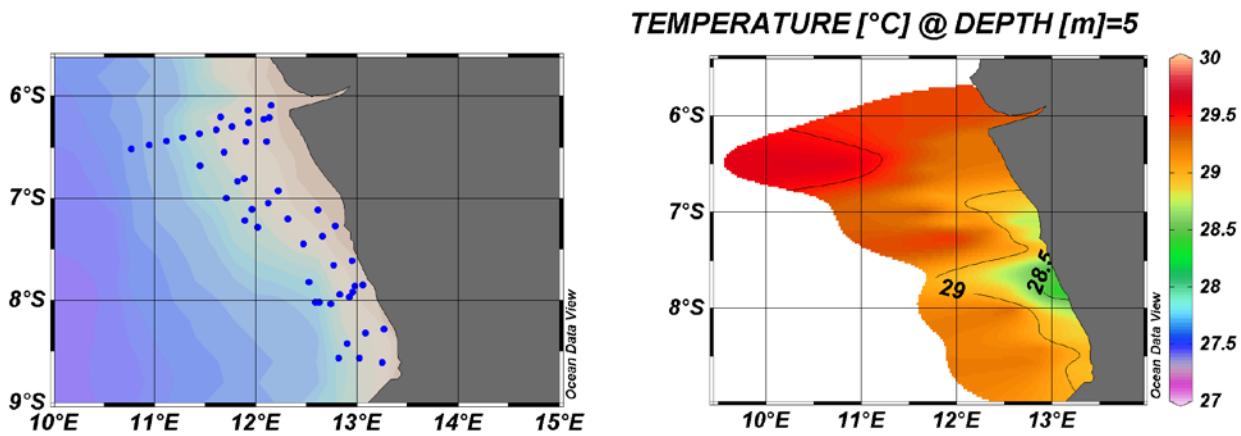

Figure 3.1 shows temperature, salinity and oxygen signature at 5 m depth. CTD data have been pooled from the present survey and the preceding pelagic survey, between 9-15 March. The temperatures ranged from 29°C to 30°C, rising from coast to offshore as from north to south. The temperatures were, in average, 4-5 °C higher than the temperature values usually recorded, such as the ones found in 2010. Salinity ranged from 32.9 to 34.8 and was lower than the values found in the 2010 demersal survey. An increasing salinity gradient was observed from north to south as from the coast to offshore. The lowest sea surface salinity value was found in the northern area of the central region; this might indicate some influence of Congo River plume such far south. Both low temperature and salinity values were found near the coast probably due to the freshwater intrusion from coastal rivers increased by rainfalls of the region. Oxygen ranged from 4.1 mg/l in north to 4.8 mg/l further south.

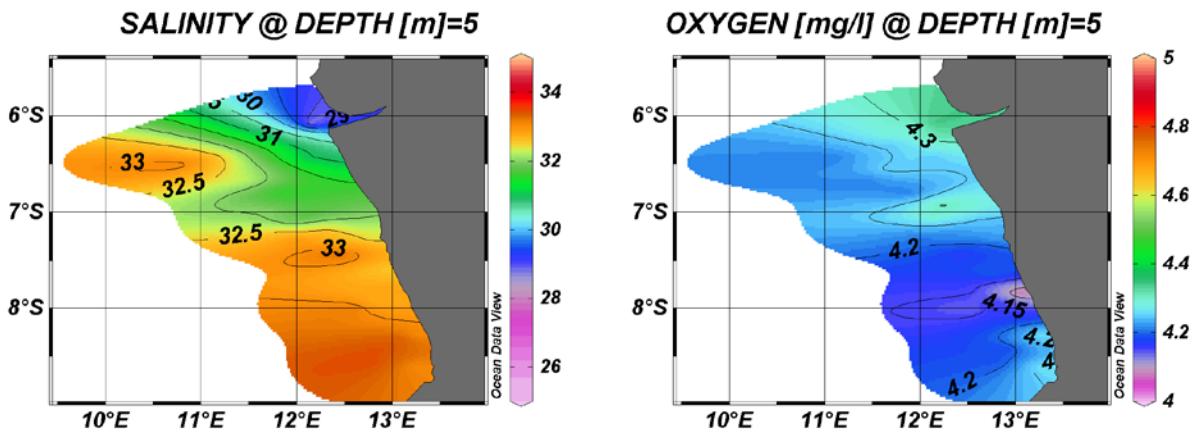

#### **Northern Region**

Over the whole region the temperatures ranged between 29°C and 30°C, which was similar to values observed in the two previous years. Temperature increased from coast to open sea. In the southern part of the region, salinity ranged from 33.0 to 33.5, while in the north it was dominated by the presence of surface water with lower salinity ( $S < 30$ ). Oxygen variation was smaller than in the central region (values ranged from 4.2 to 4.3 ml/l), with the lowest values observed in the north.

**Figures 3.1** CTD in the Central Region stations (map on the top left) are from the present survey and the preceding pelagic survey 9-15 March. From left to right: Surface distribution (5 m depth) of temperature ( $^{\circ}\text{C}$ ), salinity and oxygen (ml/l).

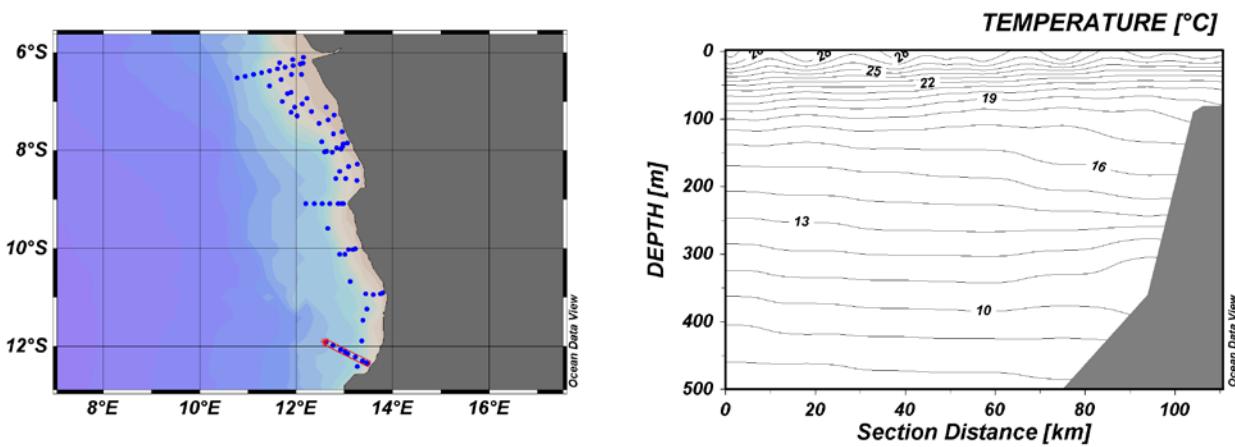

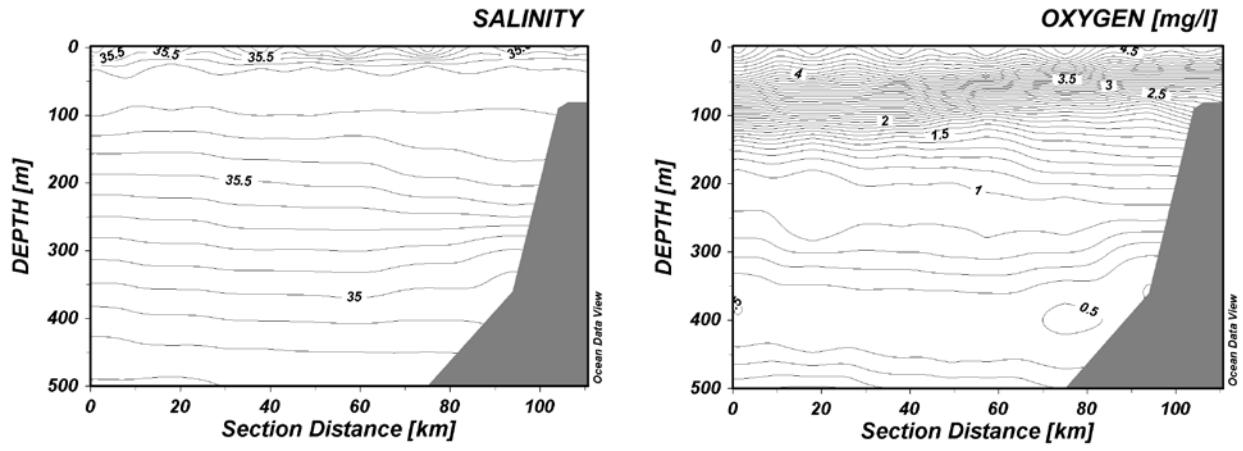

**Figure 3.2** CTD stations in the Northern Region (map on the top left). From left to right: Surface distribution, (5 m depth) of temperature ( $^{\circ}\text{C}$ ), salinity and oxygen (ml/l).

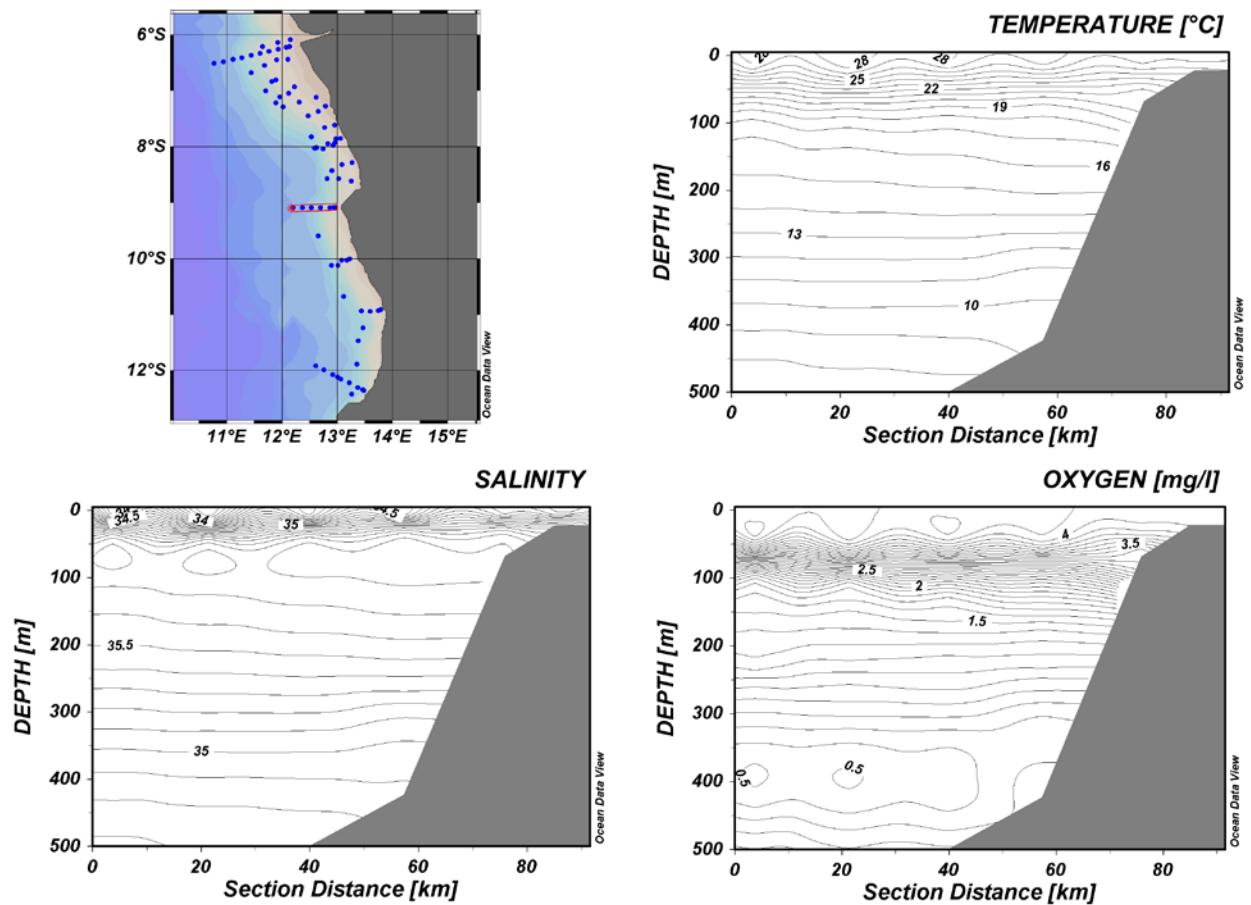

### 3.2 Vertical sections

In the Central region (Figure 3.3 - 3.4), high surface values of temperature ( $30^{\circ}\text{C}$ ) were observed in the upper layer of the Lobito transect, while salinity ranged from 35.5 to 35.7 in the surface, showing the characteristic pattern of tropical waters during summer. Over the water column, salinity also showed fairly stable conditions reaching 34.8 at 500 m. At 500 m and deeper the temperature was below  $8^{\circ}\text{C}$ . The surface layer in the transect off Ponta das Palmerinhas was characterized by waters of somewhat lower temperature ( $26^{\circ}\text{C}$ ) and slightly lower salinity than off Lobito, showing the effect of turbulence possibly caused by the intrusion of the rainfalls through the rivers. The oxygen content did not vary much in the two transects in the central region. The surface layer was dominated by waters of 4.5 ml/l  $\text{O}_2$ , while the minimum value of oxygen (1.0-1.5 ml/l) was located between 350 and 450 m depth.

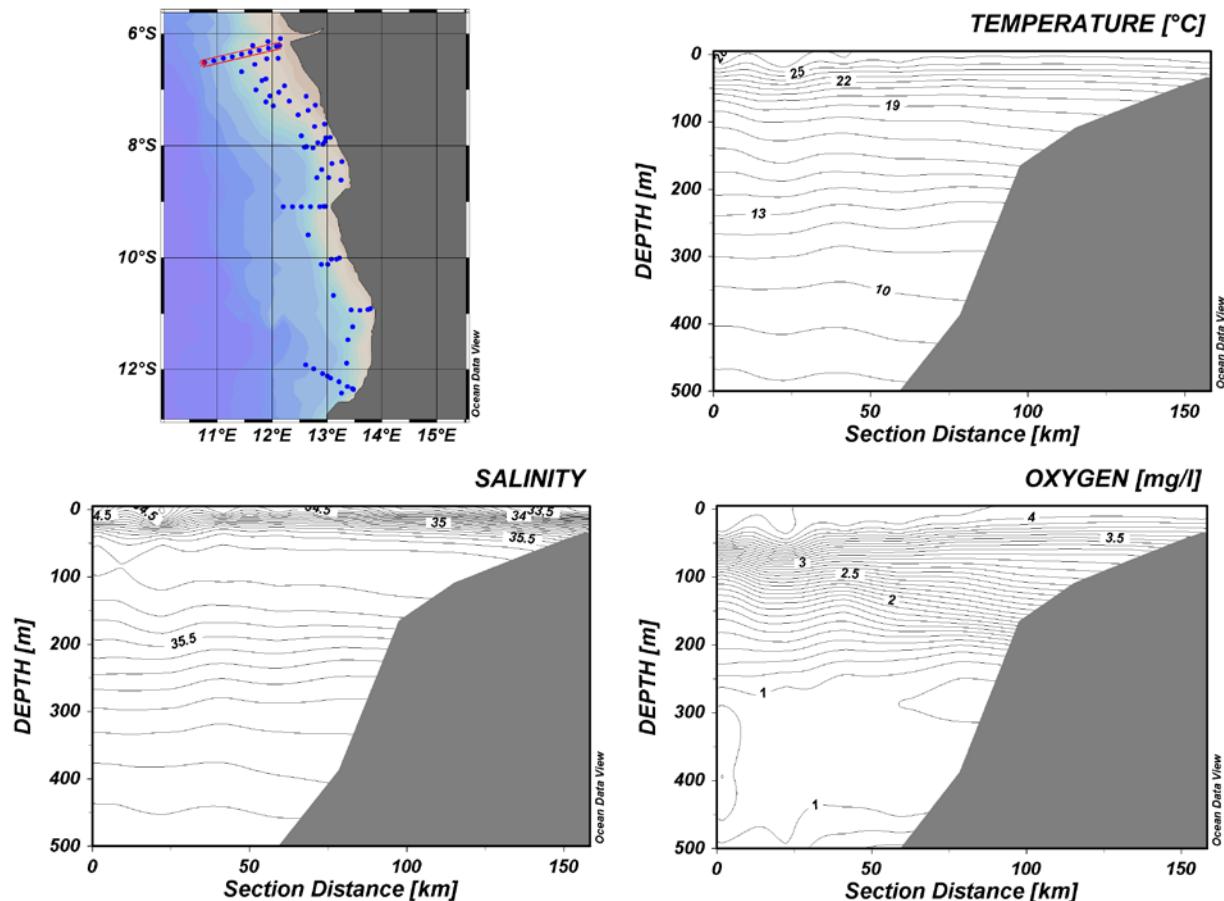

**Figure 3.3** CTD stations from Angola Central Lobito monitoring line (highlighted in red on the top left). From left to right: vertical sections of temperature ( $^{\circ}\text{C}$ ), salinity and oxygen (ml/l) off Lobito.

**Figure 3.4** CTD stations from Angola Central Pta. das Palmerinhas monitoring line (highlighted in red on the map on the top left). From left to right: vertical sections of temperature ( $^{\circ}\text{C}$ ), salinity and oxygen (ml/l) off Pta. das Palmerinhas.

In the northern region, one monitoring line was done at the Congo River (Pta. da Moita Seca) (Figure 3.5). The surface values of temperature were close to 30°C, salinity was below 34, while oxygen was about 4 mg/l. At 500 m and deeper the temperature was 8°C, the salinity was about 35, while oxygen was about 1 mg/l.

**Figure 3.5** CTD stations from Angola North Congo River monitoring line (highlighted in red on the map on the top left). From left to right: vertical sections of temperature ( $^{\circ}\text{C}$ ), salinity and oxygen (ml/l) off Congo River.

## **CHAPTER 4 CATCH RATES, DISTRIBUTION, COMPOSITION AND BIOMASS ESTIMATES OF DEMERSAL RESOURCES ON THE SHELF**

---

The inner shelf is defined to be the area between 20 and 70 m bottom depth, and the outer shelf from 71 to 200 m depth. Several of the species which inhabit the shelf, particularly the seabreams (Sparidae) and hakes (Merluccidae), are also found in deeper waters, usually in smaller densities. The results from fish distribution on the slope, below 200m, are presented in Chapter 5.

Maps with trawl station positions can be consulted in Figures 2.1-2.2, and the station information and catch by species are presented in Annex I. Pooled length distributions, weighted by the catch of the main species by region, are shown in Annex II. Further, the mean densities (tonnes·NM<sup>-2</sup>) and the frequency of occurrence of the most important species are shown in Annex III. Annex V shows the Nensis species codes used for species and groups of species, and Annex VI presents the catch rates of the same species and species groups.

### **4.1 Benguela - Ponta das Palmerinhas shelf**

The central region of Angolan waters covers the area from Benguela to Ponta das Palmerinhas. A total of 35 successful swept-area trawl hauls were accomplished on the central shelf area (Table 2.1).

The average catch was 521 kg/hour on the inner shelf and 766 kg/hour on the outer shelf (Annex VI). On the inner shelf, the demersal group was the most abundant and contributed 58% to the overall catch, the pelagic group contributed to 15% of the mean catch rate, cephalopods contributed 1.7 % whereas shrimps and sharks contributed to less than 1% of the total average catch rate. On the outer shelf, demersal fish were also more abundant than pelagic fish contributing to 40% of the average catch rate, whilst the pelagic group contributed to 30%, cephalopods contributed to 2.6 %, shrimps contributed to less than 1% of the total average catch, while no sharks were observed.

As in previous years seabreams (except *Boops boops*) were caught in most of the trawl stations on the inner shelf as well as in all stations on the outer shelf, and the average catch rates were 30 kg/hour on the inner and 98 kg/hour on the outer shelf. The most common seabreams on the inner shelf were *Pagellus bellottii* (84%) and *D. barnardi* (11%) while *D. angolensis* (35%), *P. bellottii* (34%) and *D. barnardi* (23%) were the most common seabreams on the outer shelf. Snappers were only caught on the inner shelf, although with low average catch rates (3.4 kg/h). Groupers were caught on both the inner and outer shelf, with average catch rates of 5.4 and 2.3 kg/hour, respectively. Grunts (*Pomadasys* spp.) were caught on approximately half of the stations on the inner shelf, with an average catch rate of 34 kg/hour, while on the outer shelf grunts were only caught on three stations. The average catch rate was relatively high with 114 kg/hour. However, one station particularly (#45) contributed to the high average catch rate on the outer shelf. On both inner and outer shelf, *P. peroteti* and *P. incisus* dominated among the grunts. Croakers had average catch rates of 47 kg/h on the inner shelf and 49 kg/h on the outer shelf. Catches mainly consisted of *U. canariensis* (canary drum) and *Pseudotolithus senegalensis*.

The most common pelagic groups on the inner shelf were carangids, clupeids and barracudas (*Sphyraena guachancho* and *S. sphyraena*) with average catch rates of 58, 2.5 and 5.2 kg/hour, respectively. The average catch rates of the same species groups on the outer shelf were 168 kg/hour of carangids, 2.1 kg/hour of clupeids and 0.4 kg/hour of barracudas. The hairtail (*Trichiurus lepturus*) was caught on the inner shelf with an average catch rate of 10 kg/hour, whereas on the outer shelf the average catch rate was 55 kg/hour.

### Biomass estimates

Table 4.1 shows the time series from 1985 to 2011 of swept-area biomass estimates for commercial species and groups of species on the shelf off Central Angola. The biomass estimates were calculated by stratifying by depth (20-49, 50-99 and 100-199m). The different strata have been sampled with different intensity throughout the time series and Annex VIII shows the numbers of conducted trawls by strata and survey. It must be noted that the biomass estimates presented for the pelagic species may not reflect the true biomass trends, as pelagic species are often unavailable for the bottom trawl. Therefore, the biomass estimates of the pelagic species may reflect its availability to the trawl however not their abundance. Some of the biomass estimates in Table 4.1 have a high coefficient of variation (CV), which indicates that the trends in the time series should be interpreted with care.

*T. trecae* was the only horse mackerel species found in the Central and Northern regions. The biomass on the central shelf has dramatically decreased from 2002. There was a slight indication of improvement in 2009 when the estimate was 10 000 tonnes, while the 2010 estimate of 2000 tonnes is the lowest in the whole time series. The numbers from 2011 survey show that the estimated biomass increased close to 11 000 tonnes.

*M. polli* was not caught on the shelf in 2011. The 2010 estimate of 22 tonnes was the same as in 2008 while the 2009 estimate of 4 tonnes decreased, about 80%, comparing with 2008. The estimate from 2009 was also the second lowest in the time series.

Seabreams is the most important commercially demersal fish group in Angola. The survey biomass estimates for the Central shelf have greatly fluctuated throughout the years. From 1991 to 2002, the total biomass was between 20 000 and 30 000 tonnes with a peak of 63 200 tonnes in 1998. The seabream biomass has declined since 1998 and was estimated to 5 800 tonnes in 2008, the second lowest in the time series. There was a small increase since 2009 up to the current survey, with the 2011 estimate on 9 500 tonnes. Despite this increase in biomass, the estimate numbers are still among the lowest biomass estimates in the time series.

The biomass estimate of croakers increased from 4 800 tonnes in 2006 to about 8 000 tonnes in 2007 which is the highest estimate since 1999, but decreased to 3 600 tonnes in 2008 and further to 2 100 tonnes in 2009. In 2010 the biomass was estimated to 2 700 tonnes, while the estimated biomass increased to 6 500 tonnes in 2011. *Umbrina canariensis* was the most abundant croaker, and contributed to about 61% of the total croaker biomass.

The 2011 biomass estimate of grunts (*Pomadasys incisus*, *P. jubelini*, *P. rogeri* and *P. peroteti*) was 8 600 tonnes. This was an increase compared to the 2010 and 2009 estimates of 7 600 and 5 000 tonnes, respectively. The biomass estimates have been below 10 000 tonnes during the whole time series and the present estimate is the third highest since 1998.

Catches of snappers are infrequent and low as they inhabit rocky and often untrawlable (bottom trawl) areas. Hence the biomass estimates of snappers do not adequately reflect the state of the stock.

Groupers, mainly *Epinephelus aeneus*, are found on the inner shelf and are coastal rocky and sandy shore dwellers. The 2011 survey shows an estimated biomass of 440 tonnes. The high CVs indicates that the biomass estimates of *E. aeneus* should be considered with care. There is no clear trend in the time series as the survey estimates vary largely between years.

The biomass estimate of *P. longirostris* (deep water rose shrimp) of about 20 tonnes is the lowest since 1999, much lower than the 180, 200 and 230 tonnes estimated in 2010, 2009 and 2008, respectively. *P. longirostris* is mainly distributed in the deeper parts of the shelf and the slope.

The biomass estimate of Sepiidae was 540 tonnes in 2011, while in 2010 only 2 tonnes were found on the Central shelf. The Sepiidae biomass was estimated to 120 tonnes in 2009, which was a considerable increase from the 2008 estimate of 38 tonnes. However, the annually variability and the high CVs may indicate that the estimates do not accurately reflect the state of the stock.

The biomass estimate of Ommastrephidae was 30 tonnes for this survey, lower than the 180 tonnes estimated in 2010. The annual variability and CVs are also high for this group, since 330 tonnes were estimated for 2008 followed by a decrease in 2009 and a subsequent increase in 2010.

**Table 4.1** Biomass estimates (tonnes) of important species on the shelf (20-200 m) in the Central Region. CV values are indicated in brackets.

## Distribution

Figure 4.1 shows the distribution of seabreams in the Central Region between Benguela and Luanda. The distribution covered the whole Central shelf, with higher catch rates (25-50 kg/hour) between 50 and 100m. The highest catch rates were observed in the Lobito – Benguela area.

**Figure 4.1** Distribution of seabreams (Sparidae) in the Central Region, Benguela – Ponta das Palmerinhas.  
Depth contours at 20, 50, 100, 200 and 500 m.

## **4.2 Ponta das Palmerinhas – Congo River shelf**

The survey covered the Northern Region of Angolan waters from Ponta das Palmerinhas to Congo River. The area further north from Congo River is inaccessible to fisheries surveys due to the restricted oil exploitation areas. In some earlier surveys Cabinda was covered, but to make plausible comparisons the biomass estimates in Table 4.2 only include trawl stations south of Congo River. A total of 48 successful swept-area trawl stations were sampled on the shelf area in 2011.

The average catch per hour on the inner shelf was 914 kg/hour. On the outer shelf the catch rates were 362 kg/hour. The demersal group dominated the catches on the inner shelf, with an average catch rate of 472 kg/hour and a relative contribution of 52%. The pelagic group contributed 29%, while shrimps, cephalopods and sharks contributed to less than 1% of the total. On the outer shelf, the demersal fish contributed to 53% of the mean catch rate and the pelagic group to 14%. Shrimps, sharks and cephalopods contributed to less than 3% altogether.

Seabreams (except *B. boops*) had a mean catch rate of 19 kg/h (2% of the total) on the inner shelf. On the outer shelf the average catch rate was 69 kg/h (19% of the total). The most abundant seabream on the inner shelf was *P. bellottii*, while *D. angolensis* dominated on the outer shelf. Snappers were only caught on one station on the inner part of the shelf. The catch rates of groupers were 2.0 kg/hour on the inner and 1.2 kg/hour on outer shelf, respectively. The grunts (*Pomadasys incisus* and *P. rogeri*) were caught more often on the inner shelf than on the outer shelf. The average catch rate of grunts on the inner shelf was 60 kg/hour and 17 kg/hour on the outer shelf. Croakers were relatively frequent on the shelf and the average catch rates were 74 kg/hour on the inner shelf and 22 kg/hour on outer shelf. *Pseudotolithus senegalensis* and *Pteroscion peli* were the most abundant species on the inner shelf, while *U. canariensis* was most abundant on the outer shelf.

The most common pelagic groups caught on the inner shelf were carangids (125 kg/hour), clupeids (53 kg/hour), hairtails (44 kg/h) and barracudas (42) kg/hour. Scombrids were not common in the catches (1 kg/hour). On the outer shelf carangids were still the most important group with 22 kg/hour, hairtails had an average catch rate of 18 kg/hour, while clupeids were only caught in small amounts on two stations and barracudas and scombrids were not found.

### **Biomass estimates**

Table 4.2 show swept-area biomass estimates from 1985 to 2011 for the commercial species and groups of species on the shelf off Northern Angola. The biomass estimates were calculated by stratifying by depth (20-49m, 50-99m and 100-199m). The different strata have been sampled with different intensity throughout the time series and Annex VIII shows the numbers of trawls that have been carried out by strata and survey. Again, it must be noted that the biomass estimates presented for the pelagic species cannot be trusted as a good reflection of the true biomass as the species are often unavailable to the bottom trawl. Some of the biomass estimates in Table 4.2 have a high coefficient of variations (CV), suggesting that the trends in the time series should be interpreted with care.

The biomass estimate of *T. trecae* was 4 100 tonnes in 2011, while in 2010 and 2009 the estimates were 2000 and 4 400 tonnes, respectively. The highest estimate of 37 000 tonnes was registered in 1997, while the estimates have been below 10 000 tonnes the last 10 years.

Like in 2009 and 2008 *M. polli* was not caught on the Northern shelf, throughout this survey. However, in 2010 and 2007, the biomass of *M. polli* was estimated to 26 and 37 tonnes, respectively.

The biomass estimate of seabreams on the Northern shelf was 9 800 tonnes in 2011. This is a decrease from the 13 100 tonnes estimated in 2010 and similar to the 2009 estimate, but considerably lower compared to the very high 2005 estimate of 18 300 tonnes which was the highest estimate since 1996. As in the previous years, *D. angolensis* was the dominating seabream species in the north.

The biomass estimate of croakers was estimated to 7 200 tonnes in 2011, above the 2010 and 2009 of 5 500 and 3 900 tonnes, respectively. *U. canariensis* contributed to 27% of the total estimate of this group.

The biomass estimate of grunts (*Pomadasys incisus*, *P. jubelini* and *P. peroteti*) was 6 000 tonnes in 2011, almost twice the 2010 and 2009 estimates, although lower than the relatively large estimate of 8000 tonnes in 2007.

The snappers were rare in the catch as they inhabit rocky and often unavailable areas. Hence the biomass estimates of snappers may not adequately reflect the state of the stock, which was about 80 tonnes this year.

As in the previous years, groupers, mainly *Epinephelus aeneus*, were found on the outer shelf in very low abundance. The biomass estimates since 2000 have been fluctuating around 500 tonnes. However, for this year only 260 tonnes was estimated.

The biomass estimate on the Northern shelf of *P. longirostris* in 2010 was the highest in the time series with 540 tonnes. For this survey, a significant lower biomass was estimated, close to 11 tonnes. However, the biomass estimates of this species on the shelf this year must be seen in connection with increased biomass in deeper waters.

The 2011 biomass estimate of Sepiidae was 420 tonnes. The biomass of these species on the Northern shelf is relatively low with large fluctuations from year to year.

The biomass estimate of Ommastrephidae has decreased gradually from 230 tonnes in 2008 to 40 tonnes in 2011, the same as the 2007 estimate. These are the lowest estimates in the time series since 1989. The annual biomass estimates vary and no clear trend in the abundance of Ommastrephidae can be seen from the data in Table 4.2.

The biomass estimate of sharks in 2011 was 500 tonnes. The estimate is higher than the 2010 estimate but considerably lower than the 3 300 tonnes estimated in 2000.

**Table 4.2** Biomass estimates (tonnes) of important species on the shelf (20-200 m) in the Northern Region. CV values are indicated in brackets.

## Distribution

Seabreams were distributed on the whole Northern shelf (Figure 4.2). The highest densities (> 50 kg/hour) were found on the central and outer part of the shelf.

**Figure 4.2** Distribution of seabreams (Sparidae) in the Northern Region, Ponta das Palmerinhas - Congo River.  
Depth contours at 20, 50, 100, 200 and 500 m.

## **CHAPTER 5 CATCH RATES, DISTRIBUTION, COMPOSITION AND BIOMASS ESTIMATES OF DEEP-WATER SHRIMP AND HAKE ON THE SLOPE**

---

The slope is defined in the report to be between 201 and 800 m bottom depth. The trawl positions are mapped in Figures 2.1-2.2, station information and catch by species are presented in Annex I. Pooled length distributions, weighted by catch, of the main species by region are shown in Annex II. Further, the mean densities (tonnes NM<sup>-2</sup>) and the frequency of occurrence of the most important species are shown in Annex III. Annex V shows the various Nansis species codes used for species and groups of species, and Annex VI presents the catch rates of these species and species groups.

### **5.1 Benguela – Ponta das Palmerinhas slope**

The central region of Angolan waters covered from Benguela to Ponta das Palmerinhas, and a total of 15 successful swept-area trawl stations were accomplished on the central slope.

The average catch rate on the slope was 425 kg/hour. The demersal group contributed to 87 kg/hour (20%) of the mean catch rate, while the pelagic group had an average catch rate of 7 kg/hour (1.7%). Shrimps contributed to 82 kg/hour (19%), while cephalopods and sharks contributed 1% and <1%, respectively. The “other” group of non-commercial species dominated the catches and contributed to 240 kg/hour (56%) of the total mean catch rate. *M. polli* was caught in all stations, while *M. capensis* was not found during the present survey. The average catch rate of *M. polli* was 61 kg/hour, close to the 62 kg/hour from 2010. Seabreams (*D. macrourus*) were only caught at one station, with a catch rate of 20 kg/hour. The average catch rates of *P. longirostris* and *A. varidens* were 2.7 kg/hour and 12.1 kg/hour, respectively. *Nematocarcinus africana* had an average catch rate of 66 kg/hour.

#### **Biomass estimates**

Biomass estimates, in tonnes, of the most important groups are presented in Table 5.1. The biomasses were calculated by stratifying by depth (200-299, 300-399, 400-499, 500-599, 600-699 and 700-799m). The CVs were weighted by stratum size.

The various strata have been sampled with different intensity throughout the time series and Annex VIII shows the numbers of trawls that have been carried out by strata and survey. Once more, it is important to highlight that the biomass estimates of the pelagic species may not reflect the true biomass, as pelagic species are often distributed too high in the water column to be available for the bottom trawl. Some of the biomass estimates in Table 5.1 have a high coefficient of variations (CV), which indicates that the trends in the time series should be interpreted with care.

The 2011 biomass estimate of hake (*M. polli*) was 4 300 tonnes, while 3 800, 5 300 and 6000 tonnes were estimated in 2010, 2009 and 2008, respectively. The biomass again showed a decrease, being about 1 000 tonnes lower than the 2007 and 2006 estimates. In 2004, the biomass estimate of *M. polli* showed a peak of 16 100 tonnes. Since then, the decrease has been 73%. The reasons for this reduction in biomass are not clear, but the constant decline is of concern.

The biomass estimate of seabreams this year was 270 tonnes, considerably lower than the 2 400 tonnes of the 2010 estimate. In 2009 the biomass estimate was even lower with 170 tonnes, among the lowest values in the time series. The biomass estimates of seabreams on the Central slope have fluctuated considerably in recent years and the CV of the estimates are also relatively high. *D. macrourus* was the only seabream found on only one station on the slope this year.

*P. longirostris* is distributed in depths between 200 and 400 m, and the biomass estimate increased from 220 tonnes to about 1 300 tonnes from 2003 to 2006. In 2007 the biomass estimate decreased to 190 tonnes, increased to above 400 tonnes in 2008 and decreased again to 180 tonnes in 2009. In 2010 the biomass has increased to 480 tonnes, while in 2011 the estimate was about 320 tonnes. However, the high CV in many years shows that these estimates were imprecise.

The biomass estimate of *A. varidens* was 620 tonnes in 2011, slightly lower than the 750 tonnes estimated in 2010. In 2009, a peak in the estimates (1300 tonnes) was reported.

In contrast to the two previous shrimp species, *N. africana* is not commercially important. The 2011 estimate of *N. africana* was 3 400 tonnes, a 50% reduction compared to the 2010 estimate (6 800 tonnes). The species' biomass increased from 2008, following a drop from the 2007 estimate (7 900 tonnes), the highest biomass estimate recorded.

The biomass estimate of Ommastrephidae on the Central slope was estimated to 44 tonnes, twice as much compared to 2010, the lowest value in the time series. There has been a continuous and considerable decline during the period 2005-2010. This decline followed the highest biomass estimate (510 tonnes) recorded in the time series.

Hairtails were mainly caught in the shallower areas of the slope. There was a continuous increase in the biomass from 2007 (200 tonnes) until 2010 (2 400 tonnes). However, the 2011 estimate of about 600 tonnes is only 25% of the 2010 estimate.

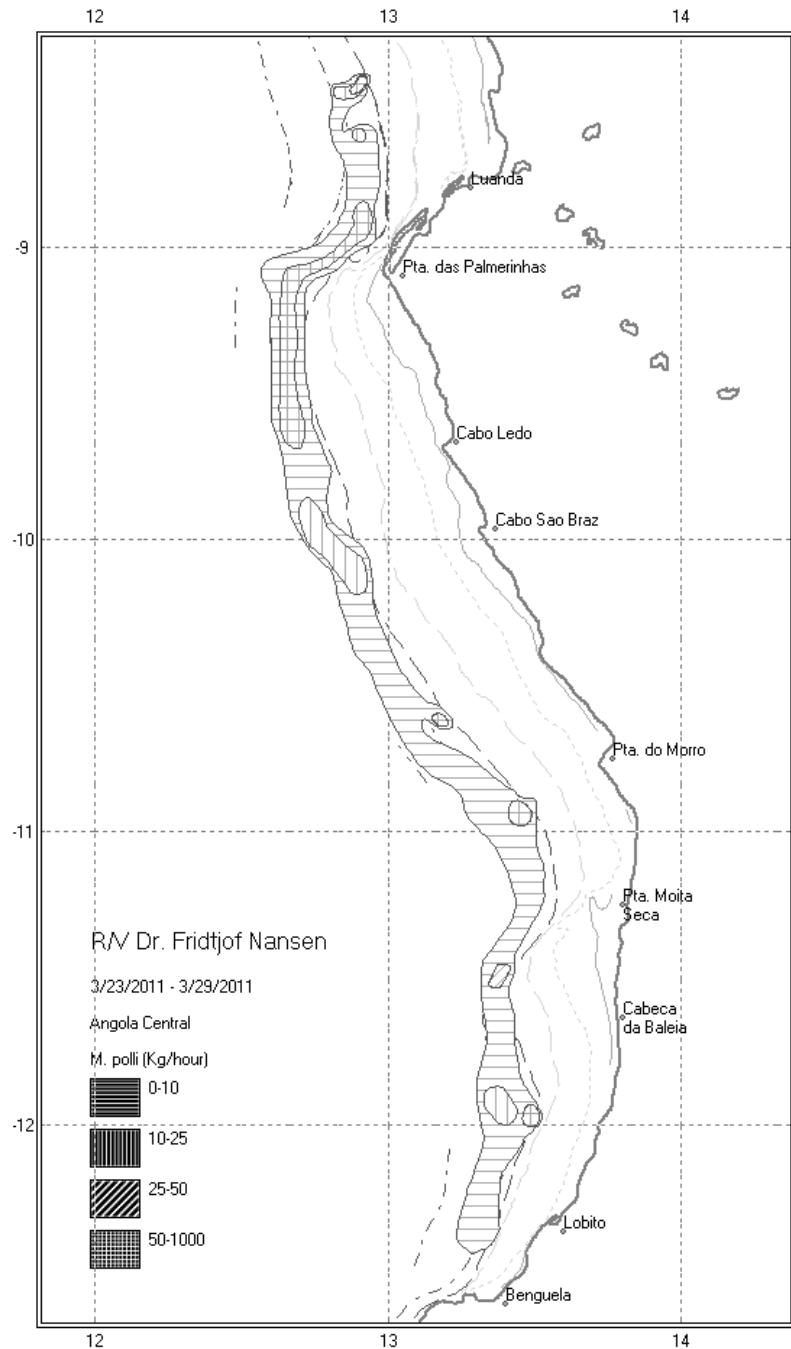

The biomass estimate of sharks was 230 tonnes in 2011. Last year, a biomass of 350 tonnes was observed, being in 2009 near 1 400 tonnes. The biomass estimates of sharks have varied considerably in recent years. Hence, the high CV and large variability in biomass between surveys show that there is no clear trend in the abundance of sharks. It is noteworthy that the sampling gear used in DFN is not adequate for this group, therefore the trawl data may reflect neither the species composition nor the true biomass trend.

**Table 5.1** Biomass estimates (tonnes) of important species on the slope (200-800 m) in the Central Region. CV values are indicated in brackets.

## Distribution

Figure 5.1 shows the distribution of hake (*M. polli*) in the Central Region. The distribution covered the whole Central slope. Some medium density concentrations ( $10 - 25 \text{ Kg hour}^{-1}$ ) were found along the whole region, being the highest concentrations ( $> 50 \text{ Kg hour}^{-1}$ ) found from Cabo Ledo until the north of Ponta das Palmerinhas, at depths between 300 and 400 m.

**Figure 5.1** Distribution of Benguela hake (*Merluccius polli*) in the Central Region, Benguela - Ponta das Palmerinhas. Depth contours at 20, 50, 100, 200 and 500 m.

## **5.2 Ponta das Palmerinhas – Congo River slope**

The survey covered the Northern Region of Angolan waters from Ponta das Palmerinhas to Congo River, and a total of 33 successful swept-area trawl stations were accomplished on the Northern slope. The area north of Congo River is currently inaccessible to fisheries surveys due to the restricted oil exploitation areas. Only stations south of the Congo River were included in the time series of biomass estimates presented in Table 5.2. The various strata have been sampled with variable intensity throughout the time series, and in Annex VIII the numbers of trawls by strata by survey can be consulted.

The average catch per hour of all species was 458 kg/hour (Annex VI); the demersal group contributed 13% to the mean catch rate, the pelagic group 2.4%, and shrimps, cephalopods and sharks each contributed 26, 1.4 and 1.5%, respectively. The “other” group dominated the catches, contributing to 56% to the total mean catch rate. *M. polli* was frequently caught on the outer shelf and the average catch rate was 23 kg/hour. Seabreams (mainly *D. angolensis*) were only caught in six stations on the Northern slope and the average catch rate was 13 kg/hour. The averages catch rates of the three shrimp species *P. longirostris*, *A. varidens* and *N. africana* were 11.7, 6.8 and 95 kg/hour, respectively. The average catch rate of *P. longirostris* should be looked with care since one station (#122) contributed to raise considerably the average catch rate of *P. longirostris*.

### **Biomass estimates**

Biomass estimates of the most important species groups are presented in Table 5.2. The biomasses were calculated by stratifying by depth (200-299, 300-399, 400-499, 500-599, 600-699 and 700-799 m). Some of the biomass estimates in Table 5.2 have a high coefficient of variation (CV), which indicates that the trends in the time series should be interpreted with care.

The biomass estimate of seabreams in 2011 was about 1 200 tonnes, slightly lower than the 2010 estimate of 1 400 tonnes. The 2010 estimate was though the highest estimate since 2000. As in previous surveys, *D. angolensis* was the most abundant seabream on the Northern slope.

The biomass estimates of *M. polli* was 2 400 tonnes in 2011, while 3 200 and 2 800 tonnes was estimated in 2010 and 2009, respectively. The estimate from this survey, is the second lowest estimate in the time series. In 2008 the biomass increased to 5 900 tonnes, after a continuous decrease from 2004 to 2007, from 15 300 tonnes 4 100 tonnes.

*P. longirostris* biomass on the slope was estimated to 1 100 tonnes in 2011. This is considerably higher than the 400 tonnes estimated in 2010 when a record high proportion (600 tonnes) was found on the shelf. The overall biomass estimates for the Northern region has ranged between 900 and 1 100 tonnes from 2005 to 2009.

The 2011 biomass estimate of *A. varidens* was about 650 tonnes, considerably higher than in 2010. A peak in the biomass was reported in 2009 with a biomass estimate of 900 tonnes, the highest since 1986.

*N. africana* biomass estimate in the present survey was around 9 000 tonnes, the lowest since 2005. Recent surveys indicated a high and relatively stable abundance of *N. Africana*.

The biomass estimate of Ommastrephidae in 2010 was 70 tonnes which is the lowest since the survey in 1995 and among the second lowest from the time series.

The 2011 biomass estimate of hairtails was about 1 100 tonnes, only half of the 2010 estimate but similar to the biomass estimates in 2009 and 2008.

The biomass estimate of sharks in 2011 was 670 tonnes, an increase in relation to the 2010 estimate of 380 tonnes.

**Table 5.2** Biomass estimates (tonnes) of important species on the slope (200-800 m) in the Northern Region. CV values are indicated in brackets.

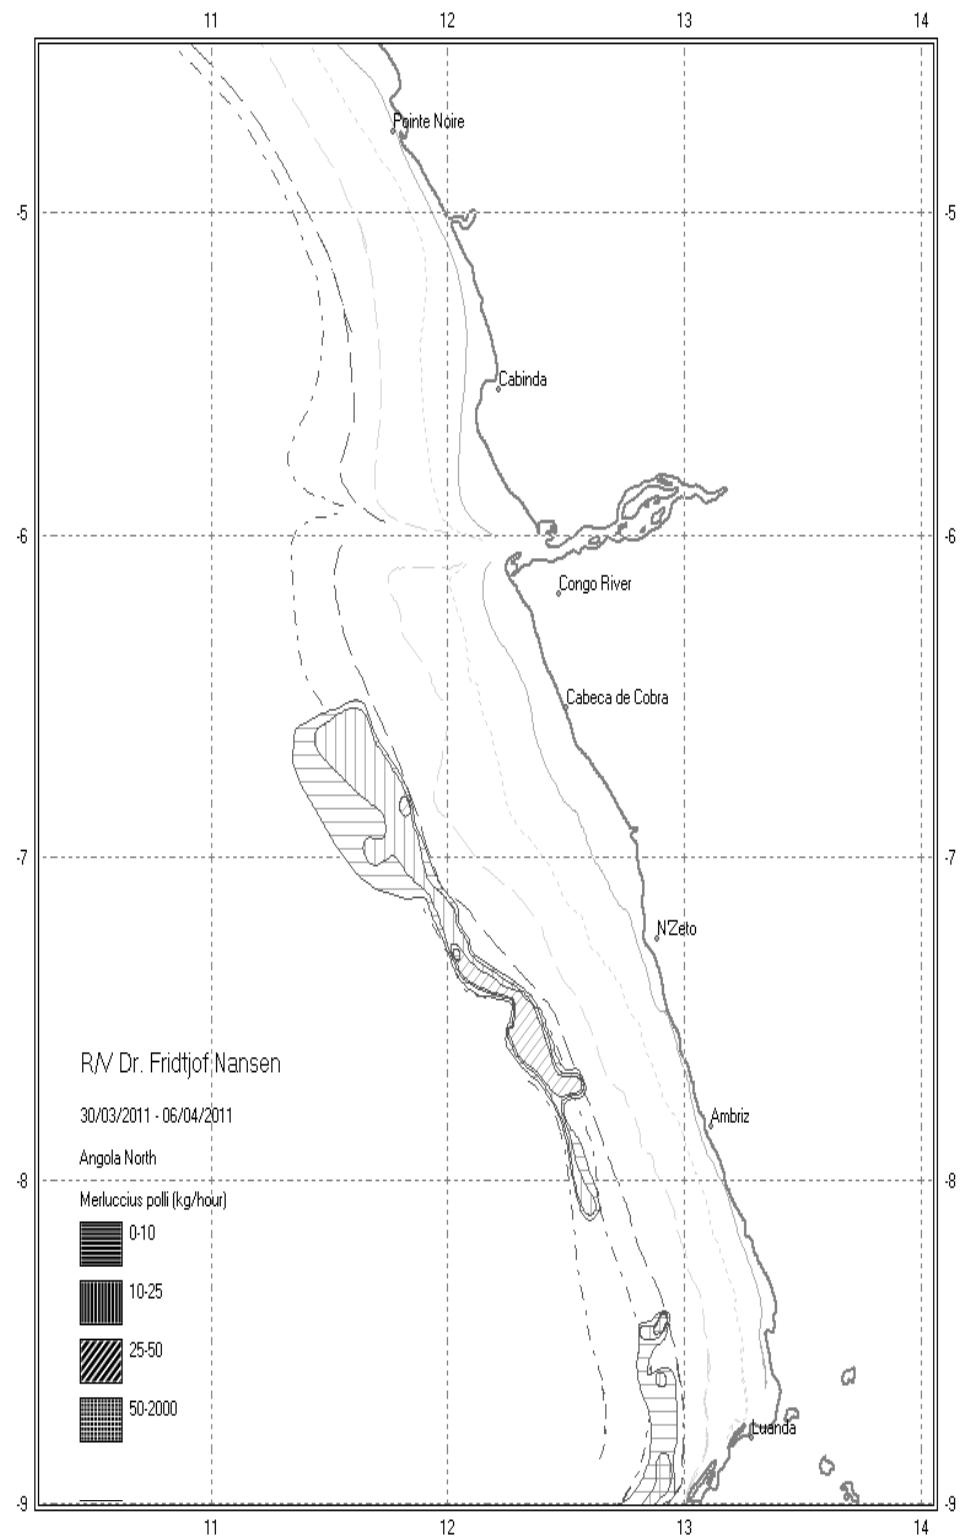

Survey	M.polli	Shrimps	Cephalopod	Sharks	Hairtails	Croakers

## Distribution

Figure 5.2 shows the estimated distribution of hake (*M. pollis*) in the Northern Region. The stock distribution covers the slope from Ponta das Palmerinhas to Cabeca de Cobra, with highest densities (25-50 kg/hour) on the upper part of the slope from Ambriz and N'Zeto.

**Figure 5.2** Distribution of hake (*Merluccius polli*) in the Northern Region, Ponta das Palmerinhas – Congo River. Depth contours at 20, 50, 100, 200 and 500 m.

## **CHAPTER 6 SUMMARY**

---

From 23 March to 8 April the 2011 demersal fish resources survey, off Angola, was carried out using R/V “Dr. Fridtjof Nansen”. Due to time constraints, only the shelf and upper slope (20-800m) from Benguela to Congo River was covered. In the Central Region the number of trawl stations was reduced by almost 30%, while in the Northern Region the number of stations was reduced by 15%.

In total, 133 trawl stations were carried out, of which 131 were valid and used in the biomass estimation of the demersal stocks. To map the oceanographic conditions 110 CTD stations were taken.

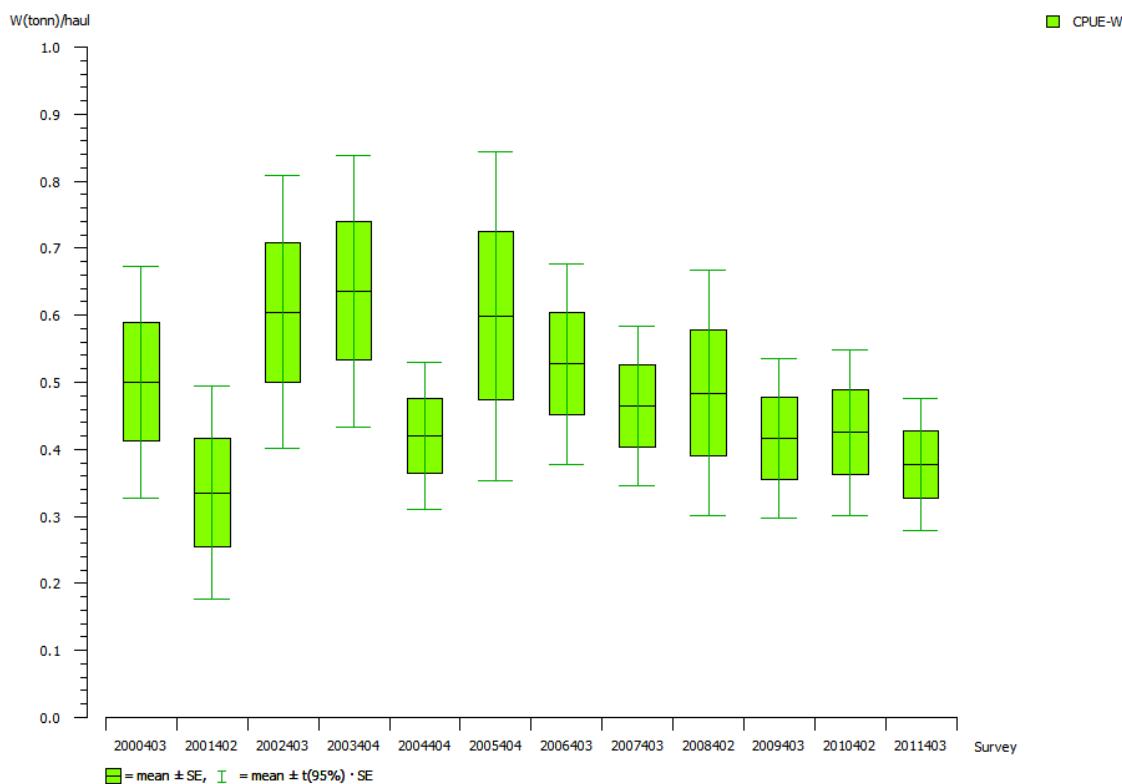

### **6.1 Hydrographical conditions**

The demersal surveys in March are coincident with the late phase of the wet season, which causes low salinity in the surface waters on the shelf off Northern and Central Angola due to the freshwater coming from the coastal rivers. This can be observed clearly in the Central Region; the temperature ranged from 26°C to 30°C rising from coast to offshore, with salinity decreasing northwards. The lowest values of both temperature and salinity were found near the coast, probably due to the freshwater intrusion from coastal rivers (Catumbela, Longa, Keve and Kwanza). The seasonal saline front area which is the characteristic pattern of this region during summer period can be observed. Another important feature is the presence of gyres near the coastal rivers possibly due to increased river flows from heavy inland rains. The Northern Region was also characterized by transport of surface water flowing towards the coast. The surface temperature ranged from 29°C to 30°C, while salinity was about 33.0 to 33.5, but lower in at the Congo River outlet ( $S < 30$ ). Oxygen showed normal values over the whole region.

### **6.2 Biomass estimates**

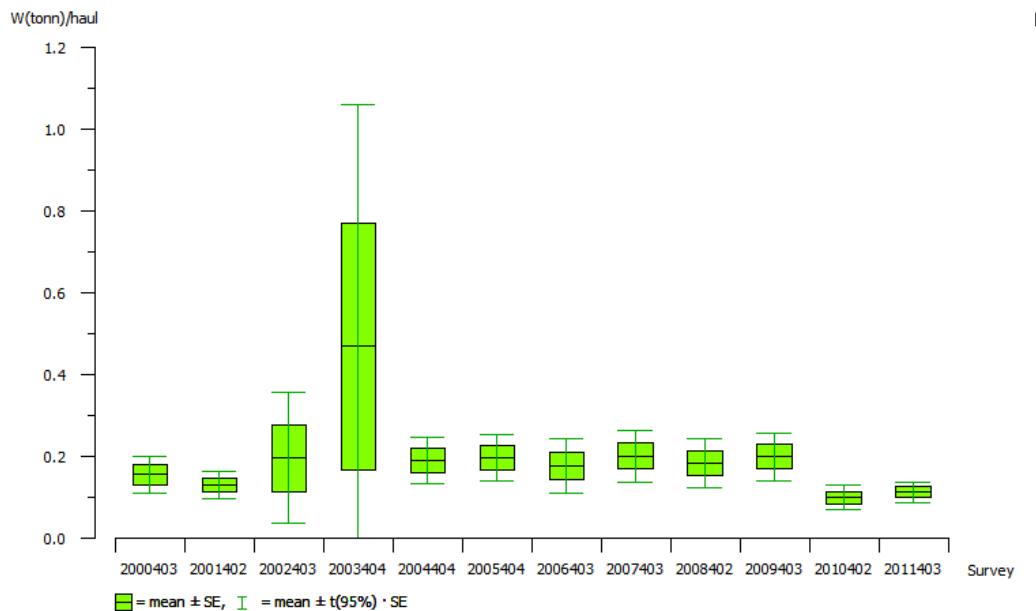

Table 6.1 presents the time series from 1985 to 2011 of the biomass estimates for the most important species on the shelf and slope in the Central and Northern regions of Angola. Angola has a high biodiversity regarding fish and invertebrate marine species. These species, despite having a low biomass individually, constitute an important fishery. Abundance trends within stocks of low biomass may show great variation, from year to year, due to low frequency of occurrence and large variability in catch rates; that, consequently, can be observed by a high CV connected to the biomass estimate. These low biomass estimates with individually large CVs may sometimes obscure the greater picture. We have therefore chosen to look at the overall trend in catch rates this year and compare these with the catch trends the last ten years when the survey methodology has been kept reasonably constant. The pelagic species (*Trachurus capensis*, *T. trecae*, *Sardinella aurita*, *S. maderensis*, *Sardina pilchardus* and *Engraulis capensis*) have been excluded from the analyses as these species are schooling pelagic species and may be caught in great abundance where they are caught, obscuring the overall tendency for the demersal species.

Overall on the shelf (Fig 6.1), there has been a declining trend in catch rates since the recent peak in 2003 when the average catch rate was approximately 630 kg/hour. In 2011, this catch rate (excluding the pelagic species) had decreased to below 400 kg/hour. The situation on the shelf should be closely monitored, being the declining catches reason for concern.

**Figure 6.1.** Average total catch/hour for all species (except the pelagic group) on the Angolan shelf (20-200 m depth) in 2000-2011.

On the slope between 200 and 800 m depth (Fig 6.2), the average catch rates have been more stable around 200 kg/hour. In 2003 the average catch rate was almost 500 kg/hour, being thus an exception to this trend. Also, the 2010 and 2011 estimates were lower than in the previous years and well below 200 kg/hour.

**Figure 6.2.** Average total catch/hour for all species (except the pelagic group) on the Angolan slope (>200 m depth) in 2000-2011.

## Seabreams

In the Central and Northern regions, the biomass estimate of seabreams in 2011 was 20 900 tonnes, a decrease from the 2010 estimate of 25 700 tonnes. The 2010 estimate was, however, the highest estimated biomass since 2005. *D. angolensis* and *D. macrourus* were the most abundant species.

## Hakes

*M. pollii* was the only hake species caught in the trawl. The estimated biomass in 2011 was 6 700 tonnes, slightly below the 7 000 tonnes estimated the previous year. There has been a continuous declining abundance of hake in the two regions since 2004 and this year's estimate is the lowest since 1999.

## Shrimps

The biomass estimate of *P. longirostris* in 2011 was 1 500 tonnes, which is about the same as in the four previous surveys. A high CV value indicates that the estimate is relatively uncertain. The 2011 estimate for *A. varidens* was 1 300 tonnes, similar to 2010, 2008 and 2007 but lower than the estimate of 2 200 tonnes in 2009.

## Grunts

The biomass estimate of grunts in the Central and Northern regions in 2011 was 14 700 tonnes, higher than the 2010 estimate (10 900 tonnes).

## Croakers

The biomass estimate of croakers, mainly *U. canariensis*, *A. aequidens*, *P. senegalensis* and *P. typus*, was about 13 900 tonnes in 2011. This is an increase from 2010 when 8 300 tonnes was estimated. *U. canariensis* contributed about 43% of the total biomass of croakers in 2011.

## Groupers and snappers

In the Central and Northern regions the biomass estimates for these groups are relatively imprecise as shown by the high CV values. The biomass estimate of groupers decreased from 1 200 in 2008 to 800 tonnes in 2009 and to 640 tonnes in 2010, while the 2011 estimate was 700 tonnes. The biomass estimate of snappers increased from 90 tonnes in 2008 to 290 tonnes in 2009, decreased to 70 tonnes in 2010 and increased again to 270 tonnes in 2011. The estimates in the time series show large fluctuations, making it difficult to identify any trends and conclude on the current state of these stocks.

## Pelagic species

For the pelagic species, the estimates of biomasses are characterized by high variability throughout the years, particularly for horse mackerel, hairtail and barracuda. The bottom trawl is not an adequate sampling gear for the pelagic fish species; therefore these species estimates do not allow establishing reliable trends for these resources.

**Table 6.1** Biomass estimates (tonnes) of important species in the Central and Northern regions. CVs are in brackets.

Survey	M.polli	T.treace	Shrimps	Cephalopod	Sharks	Clupeids	Carangids	Scombrids

## ANNEX IV Equations

### 1. Biomass estimates

The stratified estimator of mean density in the entire area is calculated as (Cochran, 1977)

$$\bar{y}_{st} = \sum_{i=1}^L W_i \bar{y}_i, \quad (1)$$

where

$L$  is the number of strata,

$W_i = \frac{\text{area}_i}{\text{total area}}$  is the proportion of the  $i^{\text{th}}$  stratum of the total survey area,

$\bar{y}_i = \frac{\sum_{k=1}^{n_i} y_{i,k}}{n_i}$  is the average density in the  $i^{\text{th}}$  stratum

$y_{i,k}$  is the density [tonnes/NM<sup>2</sup>] by the  $k^{\text{th}}$  tow in stratum  $i$

$n_i$  is the number of tows in the  $i^{\text{th}}$  stratum.

The total biomass in the area is calculated by

$$B = \bar{y}_{st} \cdot \text{total area} \quad (2)$$

The estimated variance of the biomass ( $\text{var}(\text{biomass})$ ) was calculated by:

$$\text{var}(\text{biomass}) = \left( \sum \frac{W_i^2 s_i^2}{n_i} \right) A^2 \quad (3)$$

where

$s_i^2 = \frac{\sum_{k=1}^{n_i} (y_{i,k} - \bar{y}_i)^2}{n_i - 1}$ , and  $A$  is total area

The standard error (SE) of the stratified mean was calculated as (Cochran 1977):

$$SE = \sqrt{\text{var}(\text{biomass})} \quad (4)$$

The precision for the estimates (CV) was calculated by (Zar 1999<sup>1</sup>):

$$CV = \frac{SE}{biomass} \quad (5)$$

If the sample size is “large” enough, then the Central Limit Theorem states that each time a survey is conducted there is a 95% chance that the true mean is in the interval (see Cochran<sup>2</sup>, 1977)

$$biomass \pm t_{(n-1)}SE \quad (6)$$

where  $t$  is from Students t-table with (n-1) degrees of freedom and  $\alpha = 0.025$ .

## ANNEX VI. Catch rates

Families included under each group:

Demersal: Sciaenidae, Sparidae, Pomadasytidae, Ariidae, Serranidae, Lutjanidae, Merlucciidae, Ophidiidae, Lethrinidae.

Pelagic: Scombridae, Sphyridae, Trichiuridae, Clupeidae, Engraulidae, Carangidae.

Cephalopods: squids and octopuses.

Catch rates (kg/hour) by main groups caught in valid swept area bottom trawl hauls on the shelf. Central region.

A: Inner shelf (20-70 m), B: Outer shelf (71-200 m), C: Slope (201-800 m).

A. Inner shelf (20-70 m).

## **ANNEX VII Instruments and fishing gear used**

### **Fishing gear**

The vessel has two different sized "Åkrahamn" pelagic trawls and one "Gisund super bottom trawl". During the present survey only the bottom trawl was used.

The bottom trawl has a headline of 31 m, footrope 47 m and 20 mm mesh size in the codend with an inner net of 10 mm mesh size. The trawl height was about 4.5 m and distance between wings during towing about 21 m. The sweeps are 40 m long. The trawl is equipped with a 12" rubber bobbins gear. Since 19.02.08 new and heavier "Thyborøn" combi trawl doors ( $7.41 \text{ m}^2$ , 1720 kg) have been in used. During the present survey the door distance was kept nearly constant at about 50 m at all depths by the use of a 9 m strap between the wires at 120 m distance from the doors (normally applied at depths greater than 80 m). At depths greater than 300 m the trawl was equipped with a tickler chain, which improves the catchability of bottom living and borrowing species, particularly shrimps.

The SCANMAR system was used on all trawl hauls. This equipment consists of sensors, a hydrophone, a receiver, a display unit and a battery charger. Communication between sensors and ship is based on acoustic transmission. The doors are fitted with sensors to provide information on their distance, and the trawl was equipped with a trawl eye that provides information about the trawl opening. A catch sensor on the cod-end indicated the size of the catch.

### **Acoustic instruments**

The Simrad ER-60/18, 38, 120 and 200 kHz scientific sounder was run during the survey only for observation of fish and bottom conditions. No scrutinizing of the recordings was done. Last standard sphere calibrations were carried out 23.07.2010 in Baia dos Elefantes using Cu-64, Cu-60, WC-38.1 add WC-38.1 spheres for 18, 38, 120 and 200 kHz, respectively. The details of the settings of the 38 kHz echo sounder where as follows:

#### **Transceiver-2 menu (38 kHz)**

Transducer depth	5.50 m
Absorbtion coeff.	8,5 dB/km
Pulse duration	medium (1,024ms)
Bandwidth	2,43 kHz
Max power	2000 Watt
2-way beam angle	-20,6dB
gain	25,99 dB
SA correction	-0,59 dB
Angle sensitivity	21.9
3 dB beamwidth	6,74° along ship 6,77° athwardship
Alongship offset	0.13°
Athwardship offset	0.04°

**Bottom detection menu**      Minimum level -40 dB

#### ANNEX VIII. Station allocation by survey and depth strata
