THE EAF-NANSEN PROJECT

FAO started the implementation of the project "Strengthening the Knowledge Base for and Implementing an Ecosystem Approach to Marine Fisheries in Developing Countries (EAF-Nansen GCP/INT/003/NOR)" in December 2006 with funding from the Norwegian Agency for Development Cooperation (Norad). The EAF-Nansen project is a follow-up to earlier projects/programmes in a partnership involving FAO, Norad and the Institute of Marine Research (IMR), Bergen, Norway on assessment and management of marine fishery resources in developing countries. The project works in partnership with governments and also GEF-supported Large Marine Ecosystem (LME) projects and other projects that have the potential to contribute to some components of the EAF-Nansen project.

The EAF-Nansen project offers an opportunity to coastal countries in sub-Saharan Africa, working in partnership with the project, to receive technical support from FAO for the development of national and regional frameworks for the implementation of Ecosystem Approach to Fisheries management and to acquire additional knowledge on their marine ecosystems for their use in planning and monitoring. The project contributes to building the capacity of national fisheries management administrations in ecological risk assessment methods to identify critical management issues and in the preparation, operationalization and tracking the progress of implementation of fisheries management plans consistent with the ecosystem approach to fisheries.

LE PROJET EAF-NANSEN

La FAO a initié la mise en oeuvre du projet "Renforcement de la base des connaissances pour mettre en œuvre une approche écosystémique des pêcheries marines dans les pays en développement (EAF-Nansen GCP/INT/003/NOR)" en décembre 2006. Le projet est financé par de l'Agence norvégienne de coopération pour le développement (Norad). Le projet EAF-Nansen fait suite aux précédents projets/ programmes dans le cadre du partenariat entre la FAO, Norad et l'Institut de recherche marine (IMR) de Bergen en Norvège, sur l'évaluation et l'aménagement des ressources halieutiques dans les pays en développement. Le projet est mis en oeuvre en partenariat avec les gouvernements et en collaboration avec les projets grands écosystèmes marins (GEM) soutenus par le Fonds pour l'Environnement Mondial (FEM) et d'autres projets régionaux qui ont le potentiel de contribuer à certains éléments du projet EAF-Nansen.

Le projet EAF-Nansen offre l'opportunité aux pays côtiers de l'Afrique subsaharienne partenaires de recevoir un appui technique de la FAO pour le développement de cadres nationaux et régionaux visant une approche écosystémique de l'aménagement des pêches et la possibilité d'acquérir des connaissances complémentaires sur leurs écosystèmes marins. Ces éléments seront utilisés pour la planification et le suivi des pêcheries et de leurs écosystèmes. Le projet contribue à renforcer les capacités des administrations nationales responsables de l'aménagement des pêches en introduisant des méthodes d'évaluation des risques écologiques pour identifier les questions d'aménagement d'importance majeure ainsi que la préparation, la mise en œuvre et le suivi des progrès de la mise en œuvre de plans d'aménagement des ressources marines conformes à l'approche écosystémique des pêches.

CHAPTER 1 INTRODUCTION

1.1 Objectives

This survey is one of a series aimed at monitoring the pelagic fish resources of Angola, as agreed with the Instituto Nacional de Investigação Pesqueira (INIP), Luanda, and to improve the understanding and knowledge in terms of the biology, ecology and population dynamics of the main pelagic species in relation to the environment and the whole ecosystem. Acoustic surveying using echo integration is the principal tool for estimating relative stock abundance of pelagic species, and the time series of survey estimates can therefore form a basis for recommendation on the Total Allowable Catch (TAC).

The specific objectives of the survey were the following:

- To estimate the relative abundance and map the distribution of the main commercially important pelagic and semi-pelagic fish species in Angolan waters, including the two sardinella species *Sardinella aurita* and *S. maderensis*, the Cunene horse mackerel *Trachurus trecae*, the Cape horse mackerel *Trachurus capensis* as well as other clupeid and carangid species.
- To collect biological information of target species: *T. trecae*, *T. capensis*, *S. aurita*, *S. maderensis*, *Sardinops ocellata*, *Decapterus rhonchus*, *Selene dorsalis*, *Chloroscombrus chrysurus* as well as *Brachideuterus auritus*.
- To collect stomachs and otoliths from both horse mackerel species for analyses of diet composition and length-age relationships.
- To collect depth stratified samples of zooplankton and phytoplankton in order to continue the studies on feeding biology, relating stomach contents to estimated zooplankton compositions and densities.
- To observe and make records of sea birds and sea mammals in the survey area.
- To map the general meteorological, hydrographical and biological conditions in the survey area by means of continuous recordings of weather data, CTD-casts (Temperature, Salinity and Oxygen), ADCP measurements (Acoustic Doppler Current Profiler) and plankton sampling along acoustical and hydrographical transect lines.
- On-the-job training of cruise participants on the main survey routines, including use of the Nansis database and scrutinizing acoustical observation (echograms) with the post-processing system, the Large Scale Survey System (LSSS).

1.2 Participation

The scientific staff consisted of:

From INIP, Angola:

16.06-17.07.2014: António Barradas (Angola Team leader), Francisco de Almeida, Jose da Siva, Geraldina de A. S. José, Willian Augusto, João Moraes Domingos, Eusébio Dias dos Santos and Silvana Faria (16-25.06).
26.06-17.07.2014: Marisa Macueria, Sonia da Silva and Pedro Panzo.

From Imr, Norway:

16.06-17.07.2014: Knut Korsbrekke (Cruise Leader), Inês Bernardes, Jan Frode Wilhelmsen, Håkon Langøen

1.3 Narrative

The vessel departed Luanda on the 16th of June at 16:55 UTC and steamed northwards to the Congo River where the survey started with the monitoring line off Moita Seca (Congo River) on the 17th of June at 04:00 UTC. The survey area has been divided into three regions:

Congo River - North of Pta. das Palmerinhas (6° - 9° S):

ANGOLA NORTH;

The region between 9° S and 13° S:

ANGOLA CENTRAL;

The region between 13° S and Cunene River ($17^{\circ}15'$ S):

ANGOLA SOUTH.

After a reduction in survey effort in 2013 the total survey duration was sufficient for a complete coverage of the survey area in 2014.

The northern region was completed on the 24th of June with the monitoring line off Pta. das Palmerinhas and steamed to Luanda. The vessel continued the coverage of the central region on 27th June and completed on the 4th of July. The coverage of the Southern region was completed on the 14th of July.

Calibration of the Simrad ER 60 Scientific echo sounder (18, 38, 120 and 200 kHz transducers) was done in Baía dos Elefantes on the 5th of July.

A systematic survey track implemented in 2002 consisting of pseudo-parallel acoustic transect lines perpendicular to the coast line with equally spaced transect lines (6 nautical miles, NM, apart) was followed during the survey. The Cabinda region was not included in this survey due to stricter enforcement of regulations implied by the oil companies in the area since 2009. The oil exploitation in the northern region has been rapidly expanding in the last years affecting both the length and track of some of the original acoustic lines.

1.4 Survey effort

Figure 1, 2 and 3 shows the cruise tracks with fishing, plankton and hydrographical stations for the northern, central and southern regions of Angola. The sampling trawls, including the small (10 m vertical opening), the mid-sized (15 m vertical opening) pelagic trawl and the demersal trawl (5 m), were used during the survey. Table 1 summarizes the survey effort by regions.

Table 1. Summary of survey effort by regions, including number of demersal (BT) and pelagic (PT) trawl hauls, CTD casts, Multinet stations (2-5 depth levels of zooplankton samples per station) and distance surveyed (log).

Survey region	Trawl stations			CTD	Multinet	Log (NM)
	BT	PT	Total			
Congo River - Pta. Palmerinhas	5	15	20	77	16	1178
Pta. Palmerinhas - Benguela	9	12	21	93	8	1611
Benguela - Cunene River	19	15	34	117	19	1216
Total	33	42	75	287	43	4005

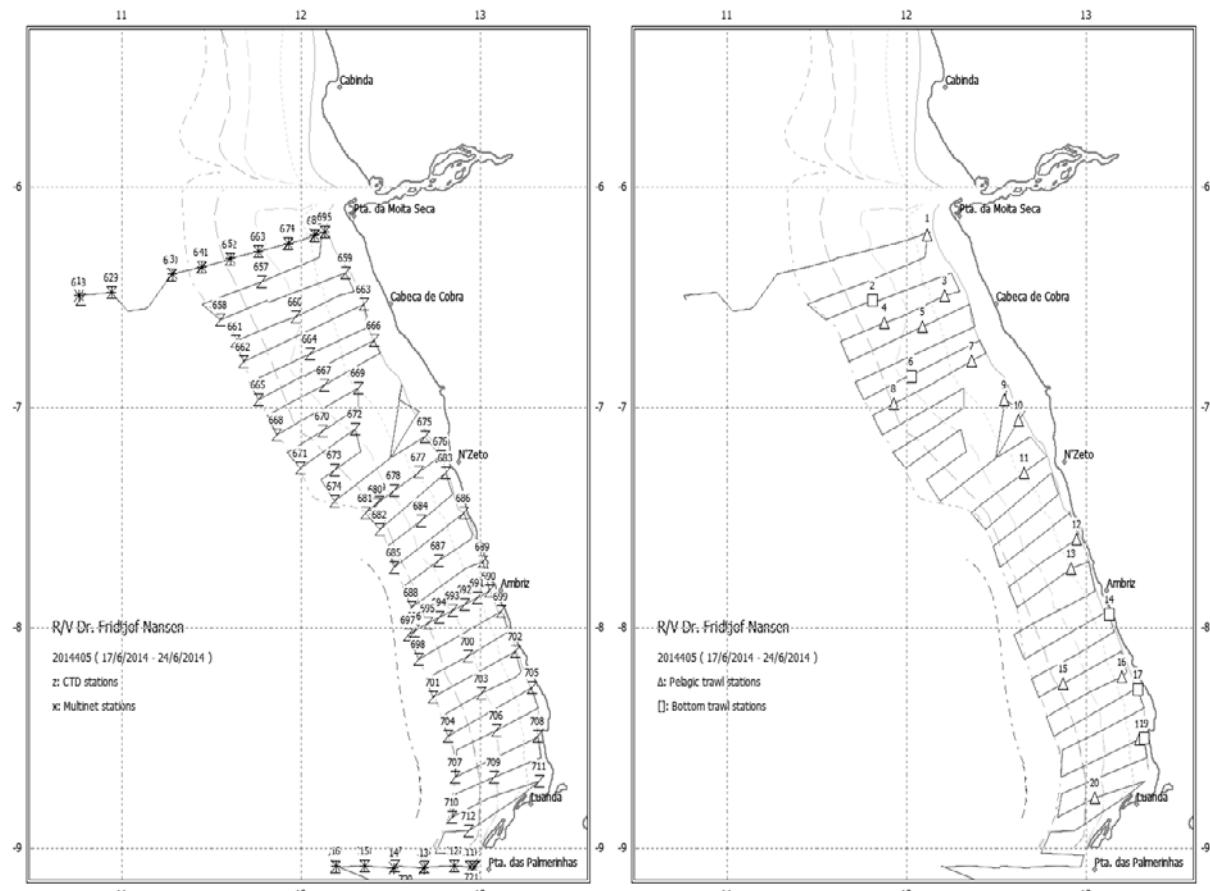

Figure 1. Course track with hydrographical and multinet stations (left panel) and trawl stations (right panel), Congo River - Pta. das Palmerinhas. Depth contours at 20, 50, 100, 200, and 500m.

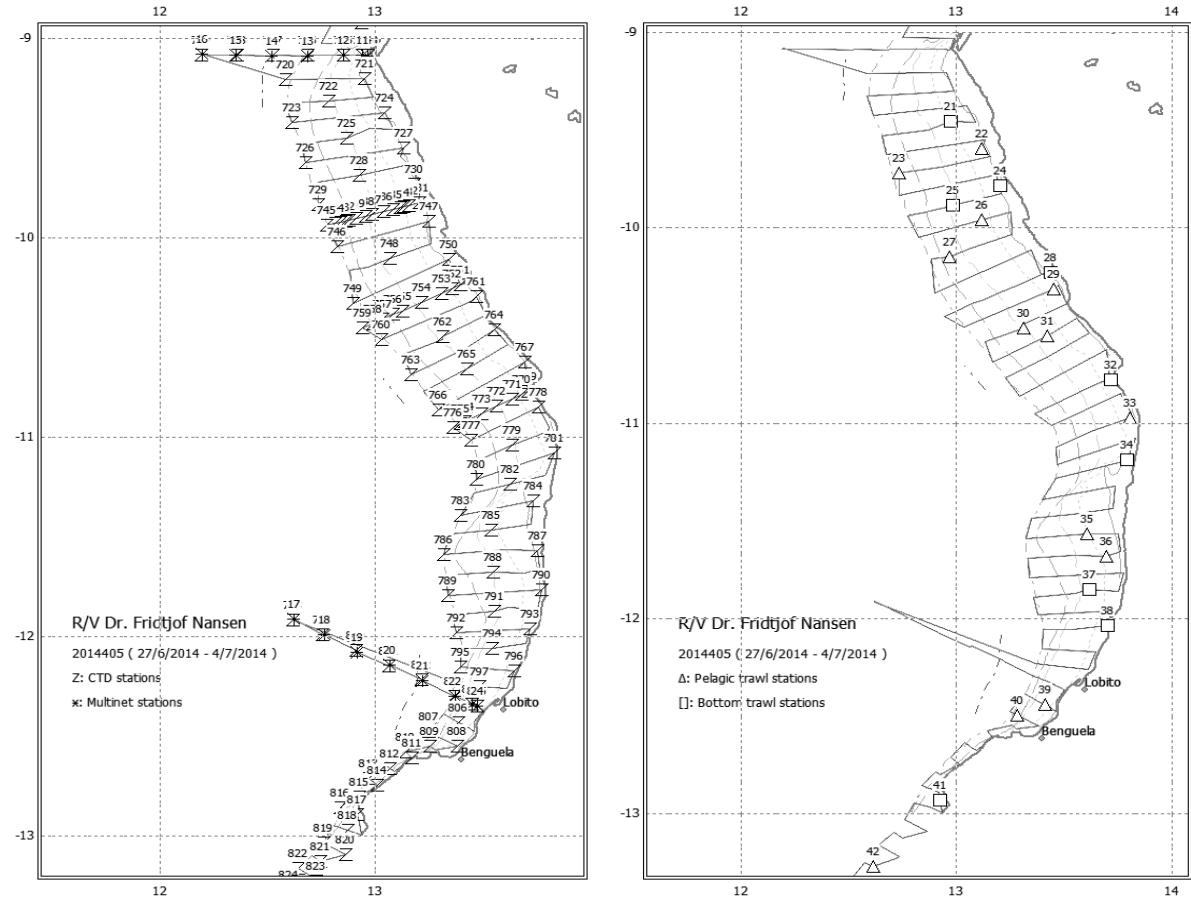

Figure 2. Course track with hydrographical and multinet stations (left panel) and trawl stations (right panel), Pta. das Palmerinhas - Benguela. Depth contours at 20, 50, 100, 200, and 500m.

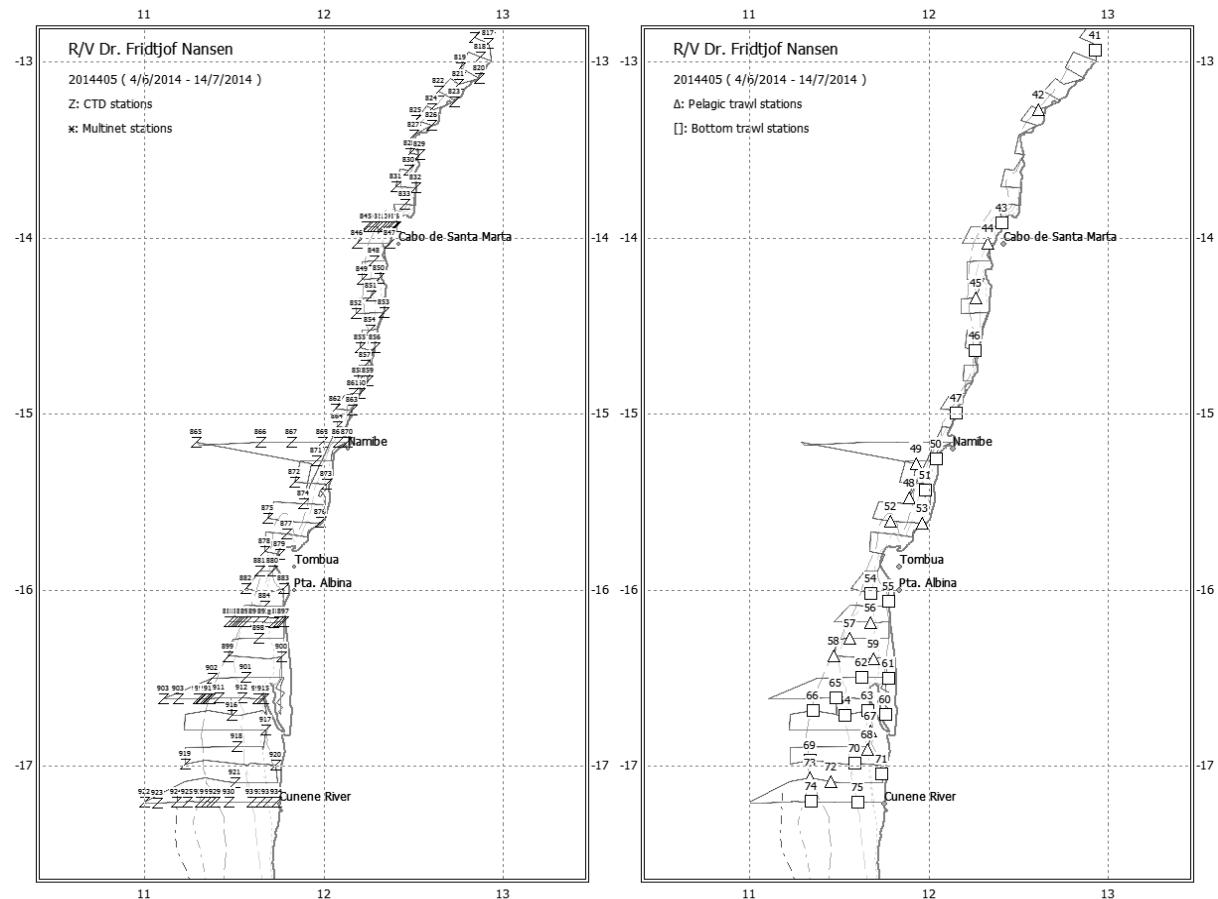

Figure 3. Course track with hydrographical and multinet stations (left panel) and trawl stations (right panel), Benguela-Cunene River. Depth contours at 20, 50, 100, 200, and 500m.

CHAPTER 2 METHODS

2.1 Hydrographical sampling

Location of stations belonging to monitoring lines or to standard hydrographical sections can be found in Table 11, ANNEX VII. Additional CTD stations were cast along acoustic transects with typically either one CTD station in the middle of the transect or two casts in each end of the transect.

The general monitoring of the oceanographic condition along the Angola coast includes Main monitoring lines of highest priority (Red) (CRML, PML, LBML, NML, CML): Multinet, bottles and CTD (Figure 4).

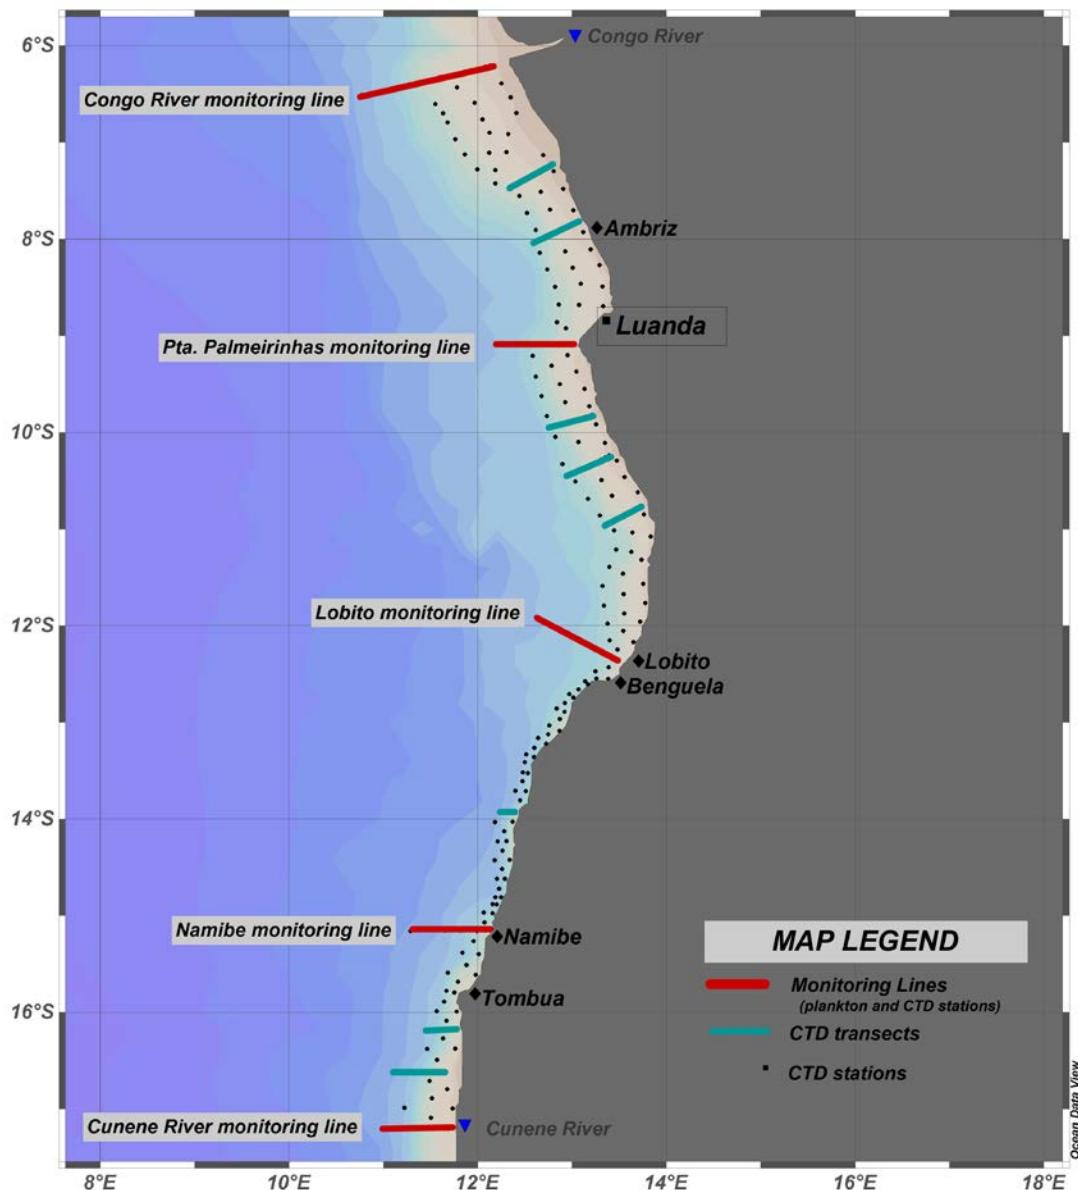

Figure 4. Monitoring lines and CTD transects in Angola. Additional CTD stations were carried out on the acoustic transects. See also Figure 1, Figure 2 and Figure 3.

2.1.1 CTD

A Seabird 911+ CTD probe was used to obtain vertical profiles of the temperature, salinity and oxygen. Real time logging was carried out using the PC based Seabird Seasave software. CTD casts were conducted at standard INIP transects and monitoring lines. The casts were stopped a few meters above the bottom, and the maximum observing depth on this survey was close 2600m. The oxygen sensor has shown to be stable, and no calibration was conducted during the survey. The CTD samples were conducted along the 5 main monitoring lines off Congo River, Pta. das Palmerinhas, Lobito, Namibe and Cunene River and 21 standards transects (for more detail see Figure 4 and ANNEX VII). CTD stations were conducted at bottom depths 20, 50, 100, 200 and 500 m along the standard transects and at different depths at main monitoring lines.

Attached to the CTD was also a Chelsea fluorometer of the type Mk III Aquatrack. It measures chlorophyll A in microgram per litre with an uncertainty of 3%. Factory slope and offset was 1.000 and -0.00.

2.1.2 Thermosalinograph

The SBE 21 Seacat thermosalinograph was running routinely during the survey, obtaining samples of sea surface salinity and relative temperature and fluorescence (5 m depth) every 10 sec. An attached in-line Turner Design SCUFA Fluorometer was continuously measuring Chlorophyll levels [RFU] at 5 m below the sea surface while underway during the entire cruise. The instrument was configured with a bright blue photodiode, a 420 nm Excitation filter and a 680 nm Emission filter. It was calibrated against the secondary orange standard dye. The maximum output was equivalent to 5Volt = 100%. It had a linear temperature compensation of 2.14%/ $^{\circ}$ C

2.1.3 Current speed and direction measurements (ADCP)

The vessel-mounted Acoustic Doppler Current Profiler (VMADCP) from RD Instruments was functioning and recorded information throughout the entire survey.

2.1.4 Meteorological observations

Meteorological data logged from the Norwegian Meteorological Institute's (DNMI) meteorological station on board, included air temperature, humidity, air pressure, wind direction and speed, and sea surface temperature (SST). All data were averaged by unit distance sailed (1 NM).

2.1.5 Mapping

To compare hydrological and biological condition between seasons, years and regions it's necessarily to produce map of comparable scales. From this survey we produce maps with scales shown in Table 2. The map scales were selected based on long term monitoring of hydrological and biological condition in the Angola waters, and the minimum and maximum observed values were selected as scale boundaries.

Table 2. Scales for temperature, salinity, oxygen and FLU (chlorophyll a) mapping.

Type of maps	Minimum value	Maximum value	Intervals
Temperature	10	32	1
Salinity	32	37	0.25
Oxygen	0	7	0.5
FLU (chlorophyll a)	0	3	0.1

2.2 Fish sampling

A brief description of the fishing gear is provided in ANNEX VI. All trawl catches were sampled for species composition by weights and numbers. Records of catch rates are given in ANNEX I. Total length (TL) frequencies were taken for the commercial pelagic species such as sardinella, horse mackerel, sardine, round herring, anchovy, *Brachydeuterus auritus* and demersal species, mainly *Dentex spp.*

Biological samples were obtained for the sardinella, *Sardinops sagax* and horse mackerel species. Total length (TL) and body weight were determined to the nearest 1cm and 1g below, respectively. Sex and reproductive stages were determined by means of macroscopic examination, scoring each fish according to the six-point classification scale used by INIP (Table 7, ANNEX III). Length and weight was recorded for the species: *Selene dorsalis*, *Caranx rhonchus*, *Chloroscombrus chrysurus*, *Engraulis encrasiculus*, *Ilisha africana*, *Etrumeus Whiteheadi*, *Scomber japonicas* and other tunas.

Stomach samples of both horse mackerel species were collected for further analysis at INIP, Luanda. Feeding biology will be investigated in more details at a later stage by relating the stomach contents to recorded availability of zooplankton.

2.3 Plankton sampling

2.3.1 Phytoplankton

Samples of phytoplankton were collected on main monitoring lines using CTD bottles at 5, 15, 25, 50 and 75 meter depths.

2.3.2 Zooplankton

The zooplankton sampling was conducted by means of HYDROBIOS Multinet (180 µm), at five depths intervals, 0-25, 25-50, 50-75, 75-100 and 100-200 m, at 5 main monitoring lines off Congo River, Pta. das Palmerinhas, Lobito, Namibe and Cunene River (see Figure 4 and ANNEX VII). Data from the flow meter was recorded electronically from the Multinet receiver unit. A SCANMAR depth sensor gave real-time information of the depth. The nets were opened and closed remotely from the bridge of the vessel. The samples were preserved in 4% formalin.

2.4 Acoustic sampling

2.4.1 Acoustic equipment

Acoustic data were recorded using a Simrad ER60 scientific echo sounder equipped with keel-mounted transducers at nominal operating frequencies of 18, 38, 120 and 200 kHz. The survey was started without *a priori* calibration. All transceivers were calibrated in Baía dos Elefantes on the 5th of July and all results were within specifications. Technical specifications and operational settings of the echo sounder used during the survey are given in ANNEX VI.

2.4.2 Allocation of acoustic energy to species group

The acoustic data were scrutinized using the LSSS version 1.6.1 (built on August 22, 2012)(Korneliussen et al. 2006). Scatters were displayed at 38 kHz. The mean 5 nautical miles (NM) area backscattering coefficient s_A (m^2/NM^2) was allocated to a predefined set of species groups on the basis established echogram features. Acoustic groups and respective species are listed in ANNEX VI. Ground truthing and estimation of mean length and weight were accomplished by means of targeted pelagic and demersal trawling.

2.4.3 Estimation of biomass

The target strength (TS) function used to convert mean area backscattering coefficient s_A (m^2/NM^2) at 38 kHz to number of fish corresponds to:

$$\text{TS} = 20 \log L - 72 \text{ (dB)} \quad (1)$$

$$\text{or } CF = \frac{10^{7.2}}{4\pi} \cdot \bar{L}^{-2} \quad (2)$$

$$\text{and on the simplest form } CF = \frac{1.2612 \cdot 10^6}{\bar{L}^2} \quad (3)$$

where CF is the conversion factor from acoustic density to fish biomass and \bar{L}^2 is the mean of squared fish lengths. This target strength function was originally established for North Sea herring, but has later been attributed to clupeids in general (Foote *et al.*, 1986; Foote, 1987).

No specific target strength relations presently are available for the species at hand, and equation (3) has therefore been applied consequently for all targeted species in this time series. The biomass was calculated by multiplying the number of fish by the expected length at weight, estimated by regression of the log-length (total) against total weight. Separate length-weight relationships were worked for each region (north, central, south), pooling all data within each region.

The boundaries of encountered fish aggregations (post strata) were determined by means of contouring within the inner and outer zero-value limits of the transect lines. The strata contours were digitised using Nansis Maptool Version 1.8. Sub-stratification was used to isolate areas of similar densities, using the following pre-defined, standard categories:

$$1: 0 < s_A < 300; 2: 300 \leq s_A < 1000; 3: 1000 \leq s_A < 3000; 4: 3000 \leq s_A (\text{m}^2/\text{NM}^2)$$

The basis for contouring is averages of five 1NM values along transects. At the end of transects and in connection with trawl stations the averaging may include fewer (from 1 to 4 single NM observations). This is a source of bias, but this bias is limited due to observations within strata having similar values. Other sources of bias of concern are the shallow distribution pattern (above integration limit), vessel avoidance behaviour of sardinella (Misund and Aglen, 1992) and inshore distribution (at depths smaller than 20meters). All estimates should consequently be considered as relative indices of abundance.

The overall length frequency distributions within strata were estimated by weighting the sample-distributions with the nearest valid 5 NM integrator value, or the average of two adjacent values. Target species of the same genus, i.e. *S. aurita* / *S. maderensis* and *T. trecae* / *T. trachurus capensis*, are not acoustically distinguishable, and the s_A values were therefore split according to the relative distributions of the two species in each length group. The total number of fish in each length group was estimated as:

$$\rho_i = \frac{\langle s_A \rangle t_{i,j} \cdot u_i}{\sum_i \frac{u_i}{C_{Fi}}} \cdot A_s = \frac{10^{7.2} \cdot t_{i,j} \cdot u_i \cdot \langle s_A \rangle \cdot A_s}{4\pi \sum_i u_i \cdot (L_i + 0.5)^2} \quad (4)$$

where: ρ_i	=	estimated number of fish in length group i
$\langle s_A \rangle$	=	mean recorded area backscattering coefficient (m^2/NM^2)
$t_{i,j}$	=	proportion of species j in length group i
u_i	=	proportion of sampled fish in length group i
A_s	=	horizontal area of stratum s
C_{Fi}	=	conversion factor for length group i
L_i	=	length group i (nearest full cm below total length)
$L_i + 0.5$	=	mean length in L_i .

CHAPTER 3 OCEANOGRAPHIC CONDITIONS

3.1 Surface distribution

Wind, sea surface temperature (SST, 5m depth), salinity (SSS, 5m depth), oxygen (SSO, 5m depth) and fluorescence (SSF, 5m depth) were continuously recorded, during the survey. The Figures in subsections 3.1.1, 3.1.2 and 3.1.3 shows the horizontal distribution of these variables.

Standardization for map presentation is needed to avoid misunderstanding and to facilitate comparisons between annual and seasonal distribution of observations, and therefore we use the same scale for all surveys in this area (for more information see Table 2 in section 2.1 Hydrographical sampling).

3.1.1 Northern region

Figure 5 shows the spatial distribution of wind in the North Angolan region. It was observed a predominance of southwest winds along the region. Weak winds (1 – 2 knots) were recorded in the coastal area north from N'Zeto to Cabeça da Cobra as south of N'Zeto until Luanda. Along most of the region, moderate winds (14 knots) have been registered, the majority coming from the North, due to the influence of Coriolis effect, which causes a left deflection of winds. In Ambriz section, strong winds were recorded, causing the stacking of water near the coast and facilitating the coastal upwelling. Strong winds were registered offshore in the areas near Congo River and Luanda while weak winds were observed closer to shore.

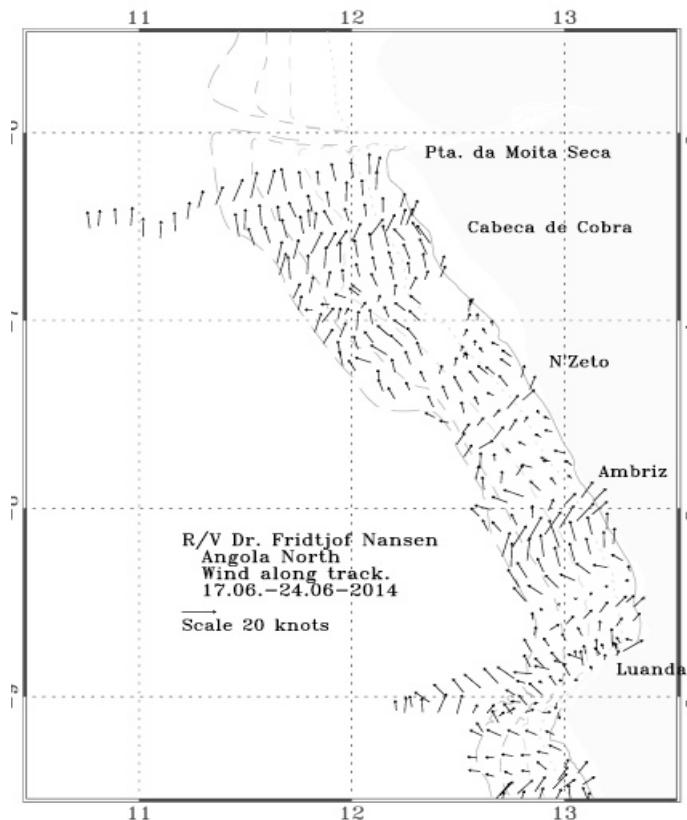

Figure 5. Distribution of wind velocities along the survey track for the northern region. Depth contours at 20, 50, 100, 200, and 500 m.

Figure 6 shows the surface distribution of temperature, salinity, oxygen and fluorescence of the North region of Angola. Most of the observed area is constituted by water bodies with temperatures ranging between 22 and 23

°C. The lowest temperatures (22 °C) were recorded along N'Zeto coast and the area between Luanda and Ponta das Palmeirinhas. The highest temperatures (26 °C) were recorded in Ponta da Moita Seca and offshore waters. Salinity ranged between 35 and 35.75. Low salinity was observed in the area of Ponta das Palmeirinhas, which might be associated to the water flow from Kwanza River.

Oxygen values ranged between 3.5 and 5.5 ml/l. The water mass with highest observed dissolved oxygen (5.5 ml/l) were observed offshore between N'Zeto and Ambriz, and offshore in Ponta das Palmeirinhas.

The high fluorescence values varying between 0.5 and 2.2 µg/l indicates high primary production.

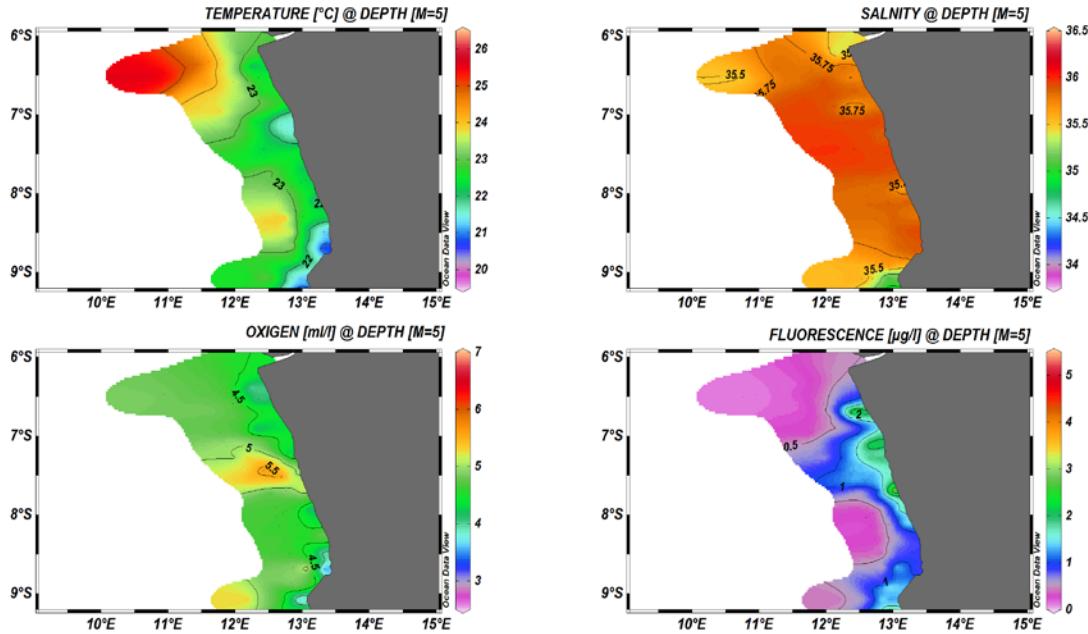

Figure 6. Surface distribution of water temperatures, salinity, oxygen and fluorescence at 5m depth in the northern region (17 June- 24 June 2014).

3.1.2 Central Region

The wind recorded along the Central Angolan region varied both in strength and direction (Figure 7). Stronger winds (15 knots) were observed mostly along Cabo Ledo section, where the formation of anti-cyclonic winds can be observed. This transports the atmospheric warm air down, warming the sea surface; while the warm air flows from the high pressure areas (A), is deflected by coriolis effect in such a way that the winds circulate, around the high pressure area, in an anti-clockwise direction. Winds with moderate intensity (≈ 14.5 knots) were observed around Ponta do Morro, North from Cabeça da Baleia and both north and south of Lobito.

To summarize, in the central region there was a predominance of the Southwest winds, together with influence of the fysical forces which have determined the dynamic changes in the region.

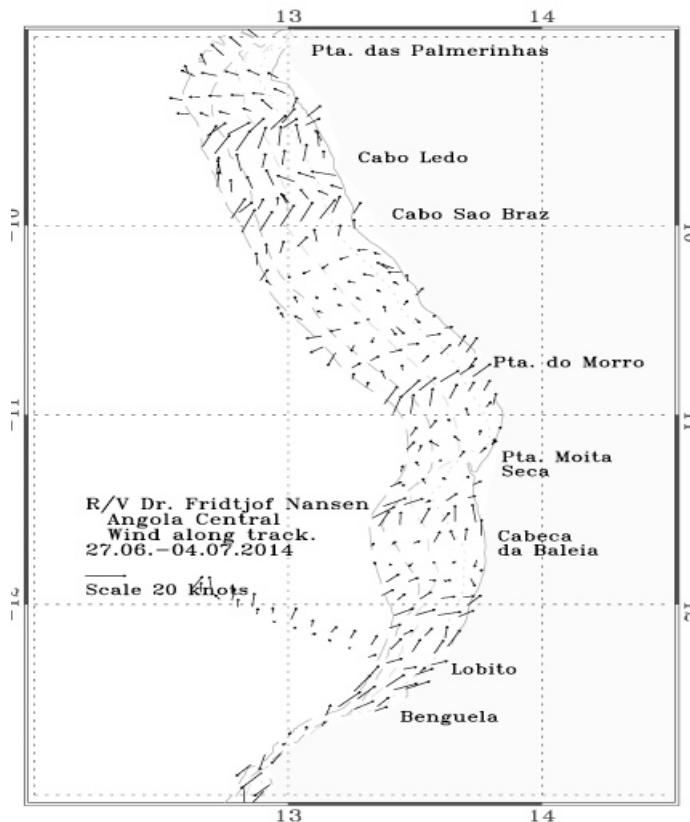

Figure 7. Distribution of wind velocities along the survey track for the central region. Depth contours at 20, 50, 100, 200, and 500 m.

The hydrographical condition in the central region is shown in Figure 8. The water surface temperature ranged between 19 and 24° C except for the coastal upwelling areas south of Benguela and the corresponding cold front. Low temperatures (19 - 21° C) were observed along the coast, between 09°49' - 13°00' S (Cabo Ledo and south of Benguela). High values were observed north of Lobito (23° C) and in Cabo de S. Braz (24° C more offshore).

Less variation was recorded for salinity (35-36). The highest levels (35.5 – 36) were observed near the coast. Oxygen concentration varied between 3 and 6 ml/l in the region. Low values (3 - 3.5 ml/l) were observed near the coast, from north of Lobito to south of Benguela, while higher values (5.5 - 6 ml/l) were found offshore along the Ponta do Morro section.

Fluorescence registrations recorded peaks in biological activity near the coast (2 - 3 µg/l) between 10°14' - 10°00' S (Cabo de S. Braz e Ponta do Morro).

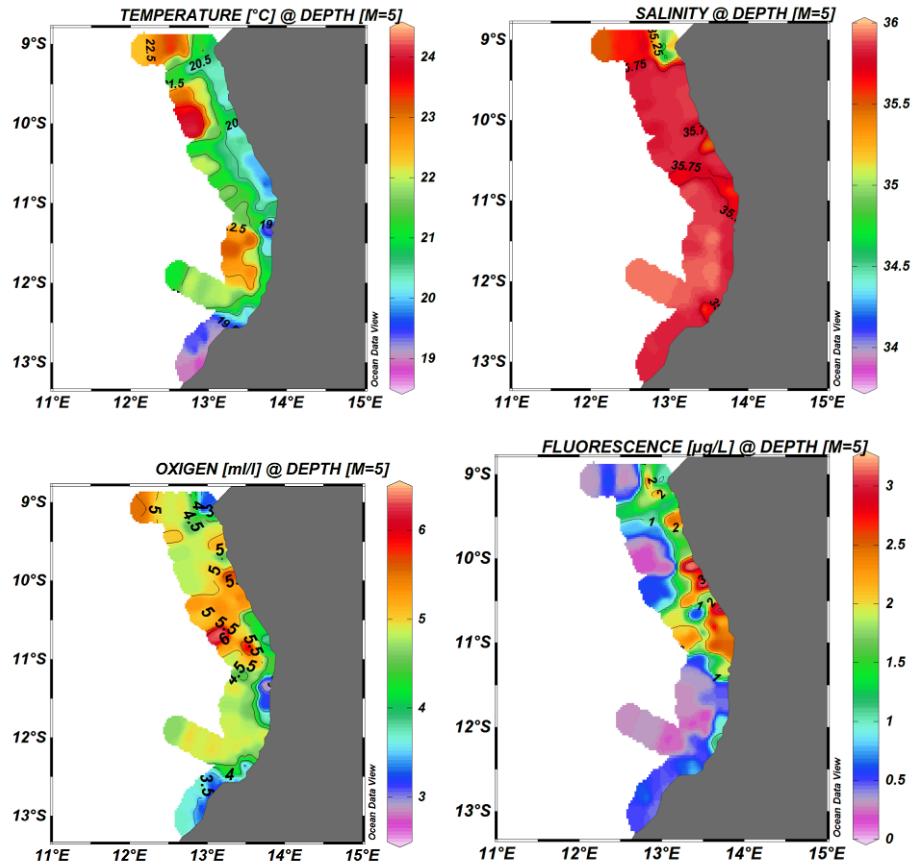

Figure 8. Surface distribution of water temperatures, salinity, oxygen and fluorescence at 5m depth in the central region (26 June- 04 July 2014).

3.1.3 Southern Region

In this region, southerly winds have predominated. Coriolis and anticyclonic winds have shown to be important for the dynamic of the area. A mix of weak (5 knots, 2 m/s) and moderated winds (14 knots, 8 m/s) were observed in the sections of Santa Marta, Tombua, Ponta Albina as south of Cunene River. In Namibe section, winds of 15 knots (10 m/s) were observed on the formation of an anticyclone offshore, directed to the coast. Along the sections of Baia dos Tigres and north of Cunene River, the strongest winds in the region were registered, reaching 50 knots (30 m/s).

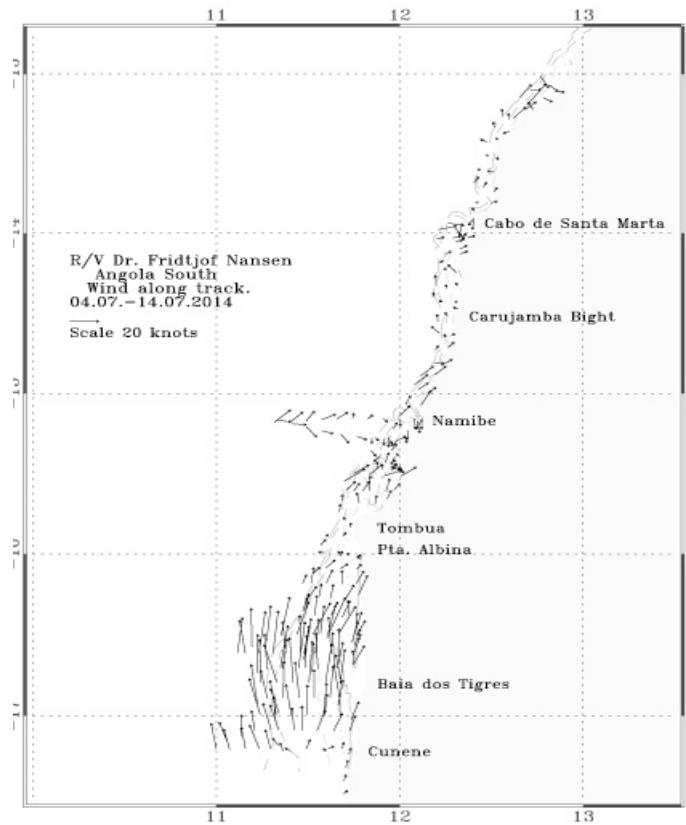

Figure 9. Distribution of wind velocities along the survey track for the southern region. Depth contours at 10, 20, 50, 100, 200 and 500 m.

The influence of the cold Benguela front can be observed in the isotherms from Figure 10. Temperature varied between 20 and 15 °C along the South Angolan coast. The highest value (20 °C), consequence of anticyclonic winds, was observed offshore in the Namibe section decreasing gradually towards the coast. The lowest value (15 °C) was observed in the sections of Baia dos Tigres and Cunene River.

Salinity showed little variation (35.4 – 36.25), with the highest value (36.25) observed in Namibe section whereas the lowest (35.4) in Cunene River.

High oxygen values (3.5 - 5 ml/l) were observed along the whole region; lower concentrations <3.5 ml/l were recorded between 13° 00 – 14° 50 S and higher (> 4 ml/l) was observed in Namibe, Tombua, south from Baia dos Tigres and in the mouth of Cunene River.

Peaks in biological activity (2.5 µg/l) were recorded in Baia dos Tigres.

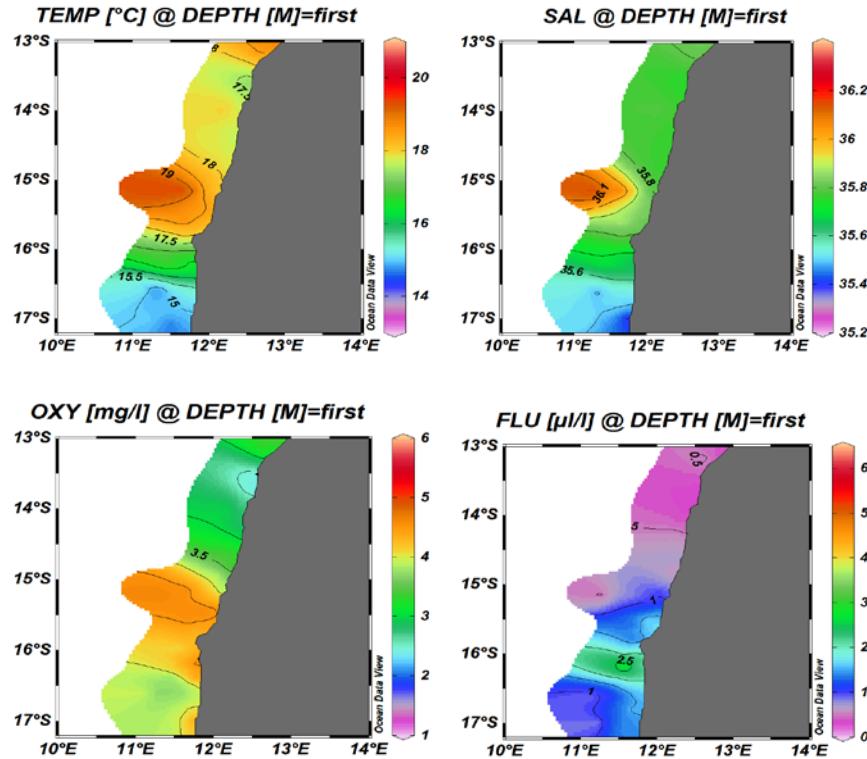

Figure 10. Surface distribution of water temperatures, salinity, oxygen and fluorescence at 5m depth in the southern region (05-14 July 2014).

3.2 Main monitoring lines

3.2.1 Northern Region

Figure 11 shows the vertical distribution of temperature, salinity, oxygen and fluorescence along monitoring line of the Congo River.

The surface temperature increases from the coast to the offshore parts ($20\text{-}24^\circ\text{C}$) and decreases with depth reaching 8°C at 500 meters, which indicates a well-defined thermal stratification without evidence of upwelling.

The high salinity values above 35.5 in the surface layer show that there is no flow of fresh water to the south of the Congo River. A similar situation was observed last year (June 2013). The intermediate waters dominate the layers below 200 m where salinity reaches the minimum values of 34.8. Oxygen in the surface layers (0-20 m) shows values of 4.5 to 4 ml / l. A layer of low levels of dissolved oxygen (<1 ml / l) was observed at depths 220 to 400 m.

The fluorescence inshore, from surface down to 50 m varied from 0.5 to 0.25 mg / l. Between 5-40 m offshore, there is a layer of higher concentration of fluorescence (> 0.5 mg / l).

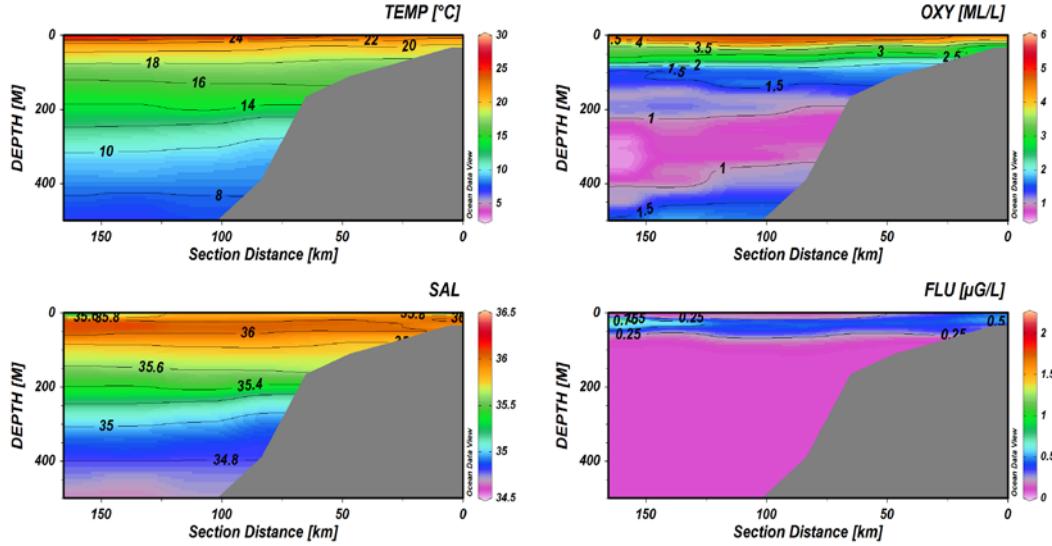

Figure 11. Vertical sections of temperature, salinity, oxygen and fluorescence off Congo River (17 June 2014).

In the Ponta das Palmeirinhas monitoring line (Figure 12), the temperature of the surface layer (0 - 20 m) was constant (17.5°C) both inshore as offshore decreasing with depth (7.5 degrees around 500 m depth).

Observed salinity at surface (0 - 200 m) was 35.5 and, near shore the values recorded were 35.75. Below 200 m depth, the salinity decreased gradually down to 34.75.

At surface, between 0 – 20 m, low oxygen levels (2 ml/l) were observed. These reached 3 ml/l near shore and below 60 m depth; the minimum oxygen zone was evident.

Fluorescence values have varied between 1 – 0.5 $\mu\text{g/l}$ inshore.

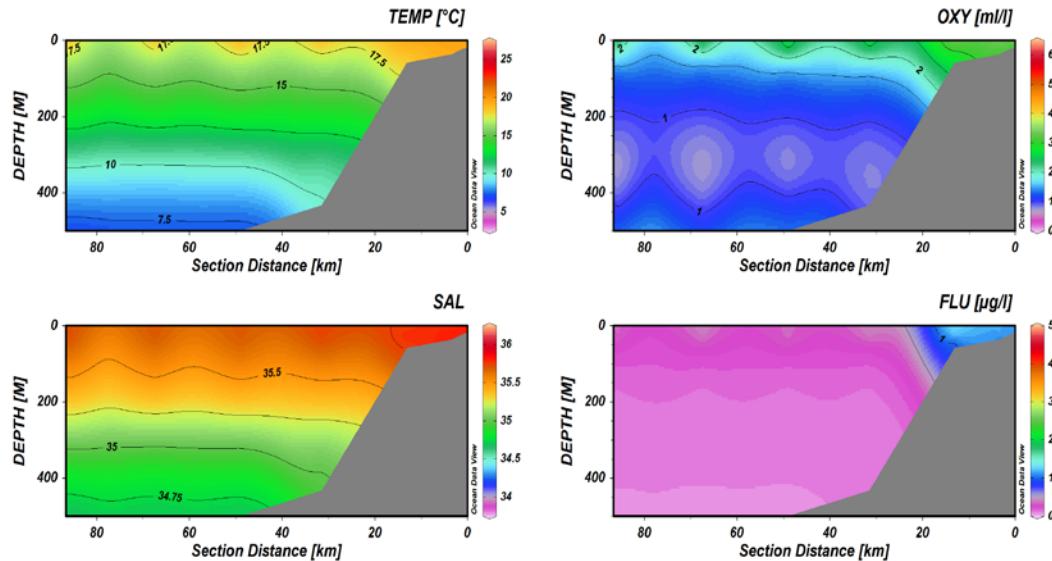

Figure 12. Vertical sections of temperature, salinity, oxygen and fluorescence off Pta. Palmeirinhas (23 June 2014).

3.2.2 Central Region

In Lobito section (Figure 13), the temperature of the sea surface ranged between $20 - 22.5^{\circ}\text{C}$, from 0 to 25 m depth. Below this depth, the values decreased with increasing depths (15°C at 100 m, 10°C at 300 and 7.5°C at 500 m).

Salinity values were stable in the surface (35.75), between 0 - 50 m, below which salinity decreased gradually reaching 35 below 250 m.

Oxygen values ranged between 3.5 and 5 ml/l in the surface waters (0 - 40 m) while lower values (<1.5 ml/l) occurred between 60 and 400 m depth.

The biological activity, showed by fluorescence levels (0.5 - 0.75 µg/l), occurred in the sub-surface layer (10 - 40 m). Near the coast and in the surface layer we observed lower values (0.25 µg/l) and similar levels were observed below 50 m depth.

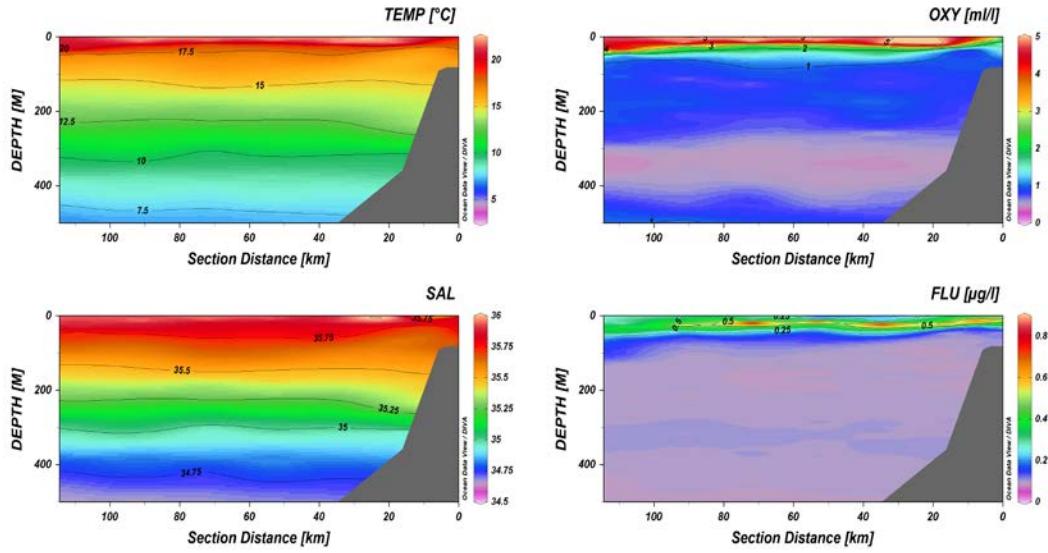

Figure 13. Vertical sections of temperature, salinity, oxygen and fluorescence off Lobito (3 July 2014)

3.2.3 Southern Region

In Namibe section (Figure 14), temperature varied from 0-50 m (20 - 17.5 °C). The highest value (20 °C), was observed at the deepening of the isobar offshore due to the anticyclonic winds along the section. Below 50 m, temperature decreases gradually with depth reaching 7.5 °C below 400 m.

Salinity shows the same profile as temperature, with high values (36.5 - 36) observed in the superficial layer offshore, while along the coast salinity stayed around 35.75. Below 50 m, salinity decreases with depth.

High oxygen values (4 - 5ml/l) were recorded all over the superficial layer, both offshore and close to shore. Below 45 m, the oxygen decreases rapidly reaching a minimum oxygen zone (<1 ml/L) at 75 m depth.

Peaks in fluorescence were recorded next to shore, with values between 2 - 1.5µg/l.

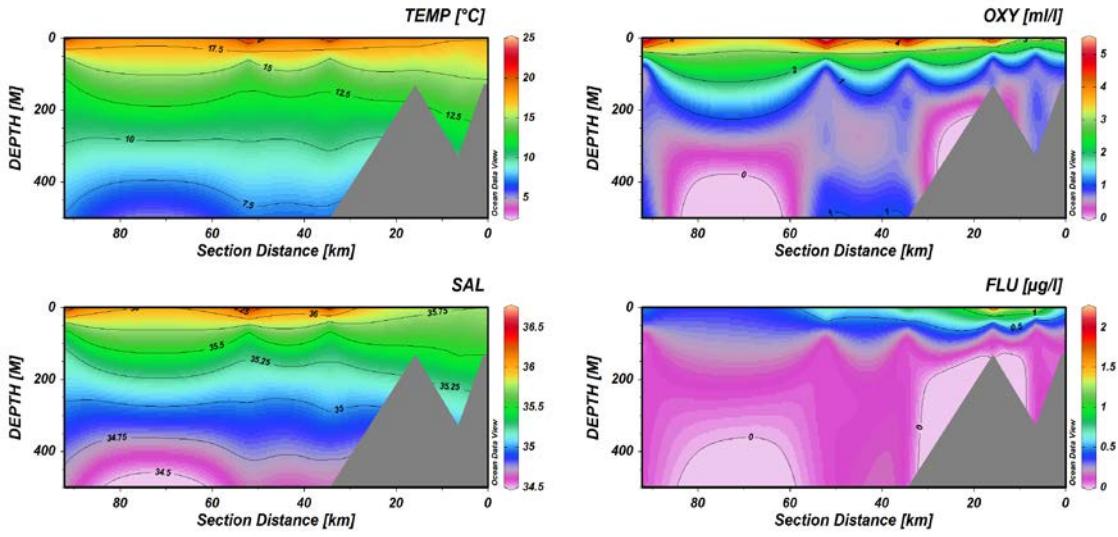

Figure 14. Vertical sections of temperature salinity, oxygen and fluorescence off Namibe (9 July 2014)

Temperature in the section of Cunene River (Figure 15) was stable (14°C) all over the superficial layer. Below 90 m, the temperature decreases gradually reaching 7.5°C at 450 m depth.

Small water pockets were observed at the surface, where the salinity was around 34.5 and, below 50 m, salinity is gradually decreasing.

Oxygen also presented stable values around 3.5 ml/L in the surface layer offshore. Near the coast, below 50 m, the values ranged between 3 and 2.5 ml/L , being the lowest value ($<1 \text{ ml/L}$) registered at 100 m depth.

The peak of biological activity, determined by fluorescence, was registered in a sinking of superficial waters close to the shore, where the values ranged between 1 and $1.5 \mu\text{g/L}$.

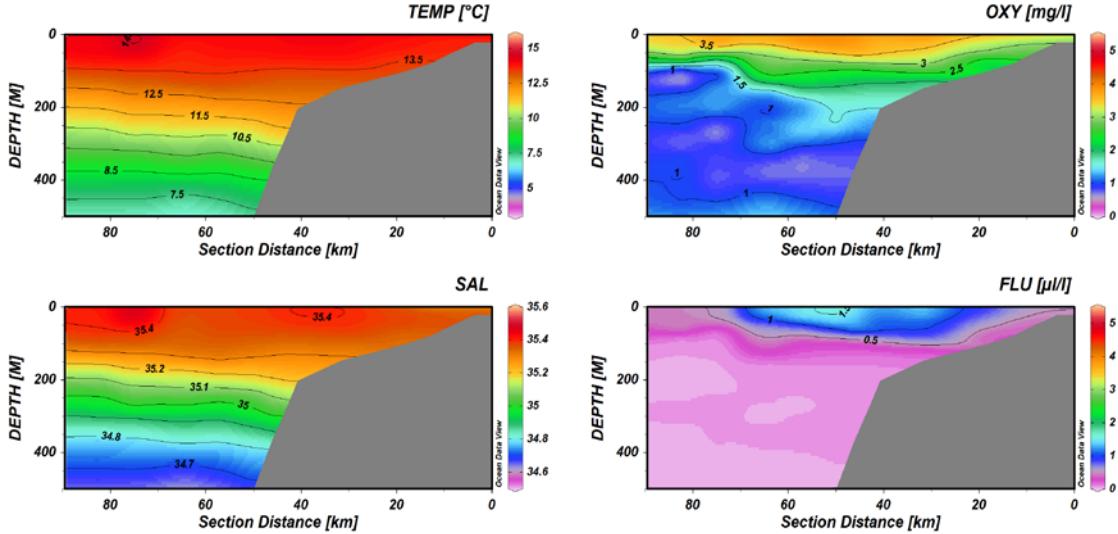

Figure 15. Vertical sections of temperature salinity, oxygen and fluorescence off Cunene River (14 July 2014)

CHAPTER 4 DISTRIBUTION, SIZE COMPOSITION AND BIOMASS ESTIMATES

4.1 Congo River - Pta. Palmerinhas

4.1.1 *Sardinella*

The sardinella were distributed over two separated areas (Figure 16). The northernmost area was located near the Cabeça da Cobra, while the other extended from South of Cabeça da Cobra to Ponta das Palmeirinhas. Both areas showed low densities ($0 < s_A < 300 \text{ m}^2/\text{NM}^2$). Some areas with slightly higher concentrations ($301 < s_A < 1\,000 \text{ m}^2/\text{NM}^2$) were patchily distributed south from Cabeca da Cobra to Ponta das Palmeirinhas.

The sardinella occupied a larger area then in 2013, but with considerably lower echo densities. The more widespread distribution is a lot more similar to the 2012 distribution with substantial registrations made beyond the 100m depth contour.

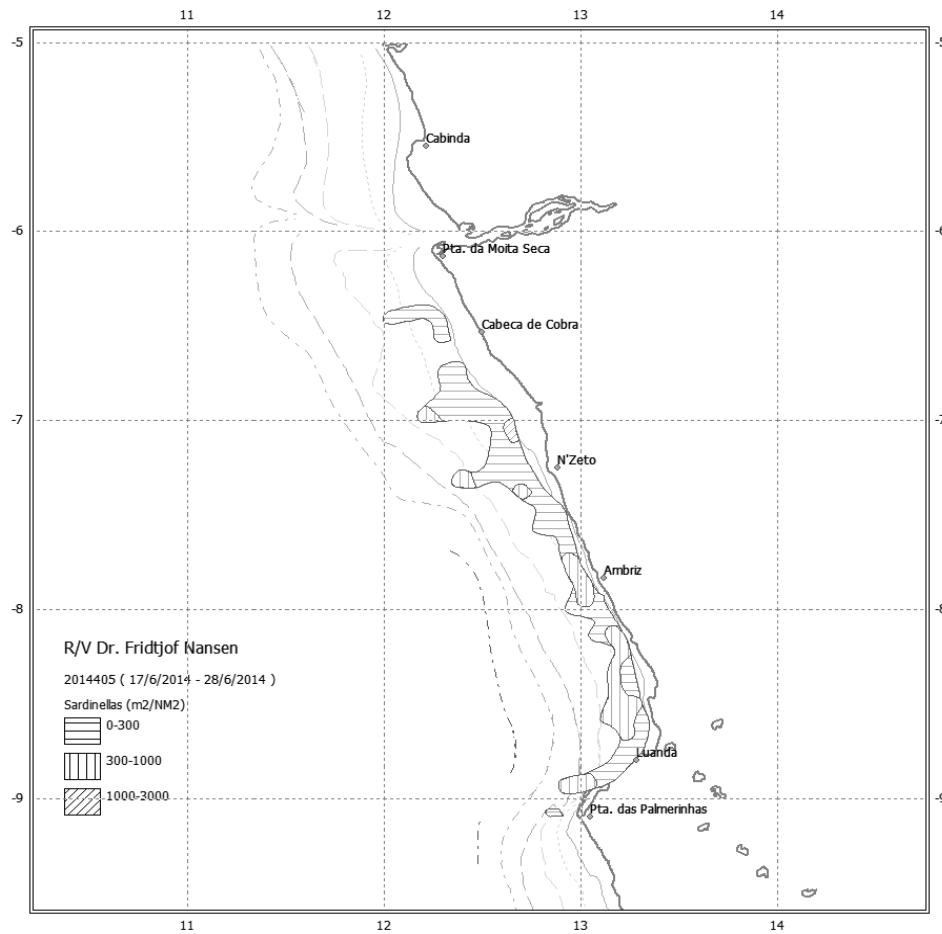

Figure 16. Distribution of *Sardinella maderensis* and *Sardinella aurita*. Congo River-Pta. das Palmeirinhas Depth contours at 20, 50, 100, 200, and 500m.

Figure 17 shows the length distribution of the sardinellas in the northern region. *S. maderensis* showed two modal peaks around 16 and 26 cm TL, and 50 % of the fish were dominated by fish of 8-20 cm. *S. Aurita* showed four modal peaks around 7, 17, 26 and 31 cm TL, and the total abundance dominated by fish of 6-20 cm length (86%).

The estimated biomass for this region was 140 208 tonnes, (*Sardinella maderensis* was 124 380 tonnes and *Sardinella aurita* was 15 828 tonnes). The total biomass is somewhat higher than for the same period in 2013 (117 mil tonnes), but lower than the biomass estimated in 2012 (210 mil tonnes). *Sardinella maderensis* represented about 89% and *S. aurita* 11% in the northern area.

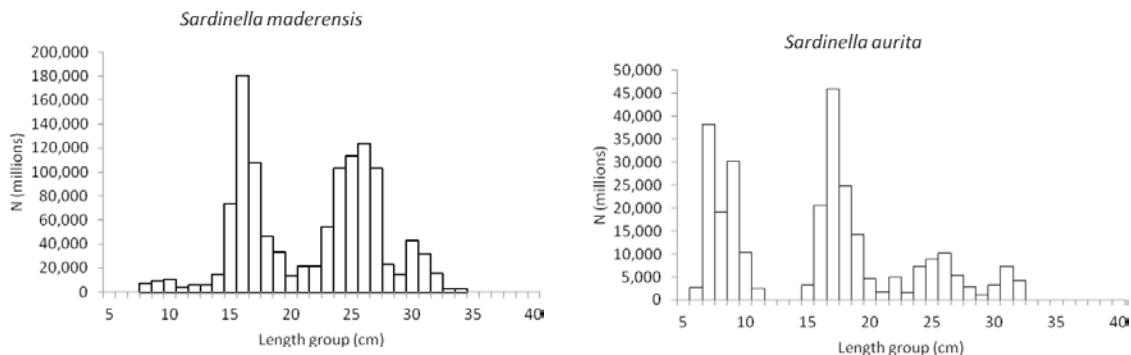

Figure 17. Total length distribution of *Sardinella maderensis* and *Sardinella aurita*, Congo River-Pta. das Palmerinhas.

4.1.2 Horse mackerel

Cunene horse mackerel, *T. trecae*, was found in scattered and in small areas offshore, from Pta. da Moita Seca to Luanda (Figure 18). The fish were observed in low-density areas ($0 < s_A < 300 \text{ m}^2/\text{NM}^2$). Compared with last year, between south of Ambriz and Luanda, there is a reduction of the area of distribution of *Trachurus trecae*. During this survey, the species occupied only two small areas, located more offshore. Along the North region, most fish were captured between 25-130 m depth. The horse mackerel was generally caught with bottom trawl during the day and pelagic trawl during the night, and mixed with Clupeoids, Hairtails and Sardinellas, depending on depth.

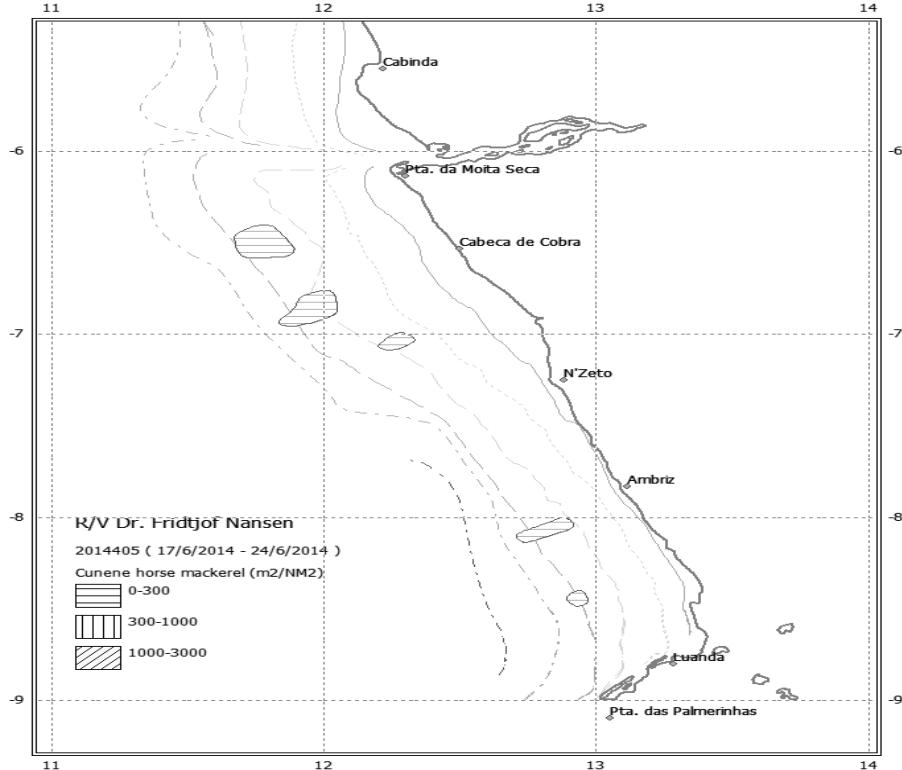

Figure 18. Distribution of Cunene horse mackerel (*Trachurus trecae*), Congo River-Pta. das Palmerinhas. Depth contours at 20, 50, 100, 200, and 500 m.

The length frequency of Cunene horse mackerel, *T. trecae*, consisted mainly of juveniles with lengths ranging from 10-17 cm, and a few adult specimens. The juveniles dominated with about 97% of the fish in the region (Figure 19).

The biomass of Cunene horse mackerel was estimated to 862 tonnes, corresponding to approximately 28 million fish. The bulk of biomass belongs to juvenile fish of 10-20 cm length, while the adult fish of 21-50 cm contributed 3% only. The observed biomass was much lower in comparison to the last three years of the time series. The observation and estimation of fish at such low densities and abundance is highly uncertain and the point estimate should be used with caution.

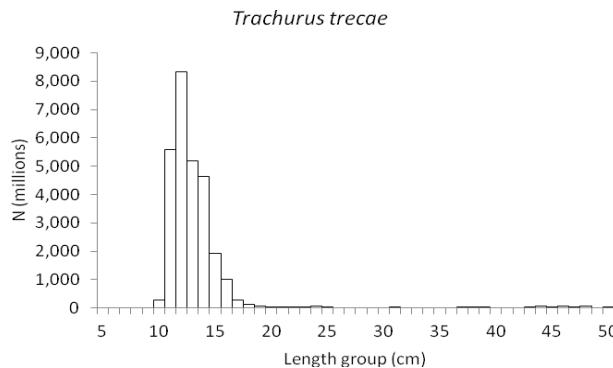

Figure 19. Total length frequency distribution of Cunene horse mackerel, Congo River - Pta. das Palmerinhas.

In 375 biological samples from the north area, 27% of the fish were found to be mature, 73 were immature. The majority of the fish were found in stage I and II for both female and males, but for stage V mostl fish were females. The length at 50% maturity of *Trachurus trecae*, of this region, was 20 cm (Figure 20). Please note that the number of sampled fish above 20cm is low and that results are given with some uncertainty.

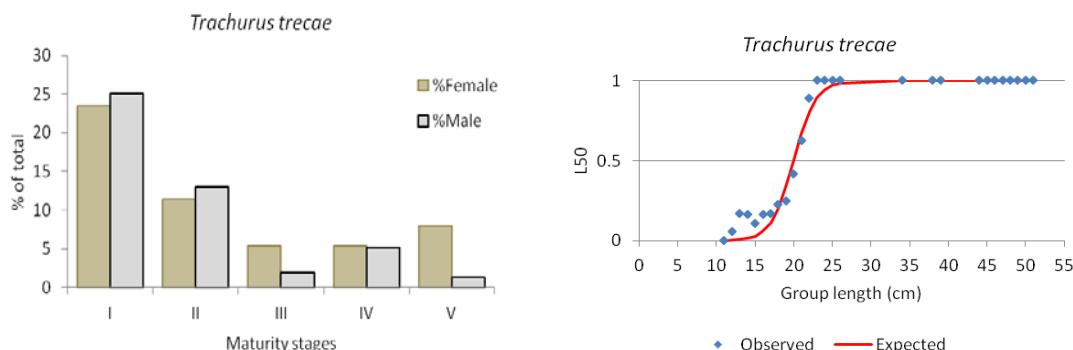

Figure 20. Maturity stages by sex and first length at maturity of *Trachurus trecae* in the Northern region.

4.1.3 Pelagic species Group 1

During the survey in 2014, *Ilisha africana* was the only species found belonging to this group. *Ilisha africana* was patchily distributed between Pta. da Moita Seca and Cabeca da Cobra, offshore. The species was found in inshore waters between south of NZeto and Ambriz to Pta. Das Palmerinhas. In all areas we observed low densities ($0 < S_A < 300 \text{ m}^2/\text{NM}^2$) of *Ilisha africana* (Figure 21). Only a few *Engraulis encrasicolus* were found in the area.

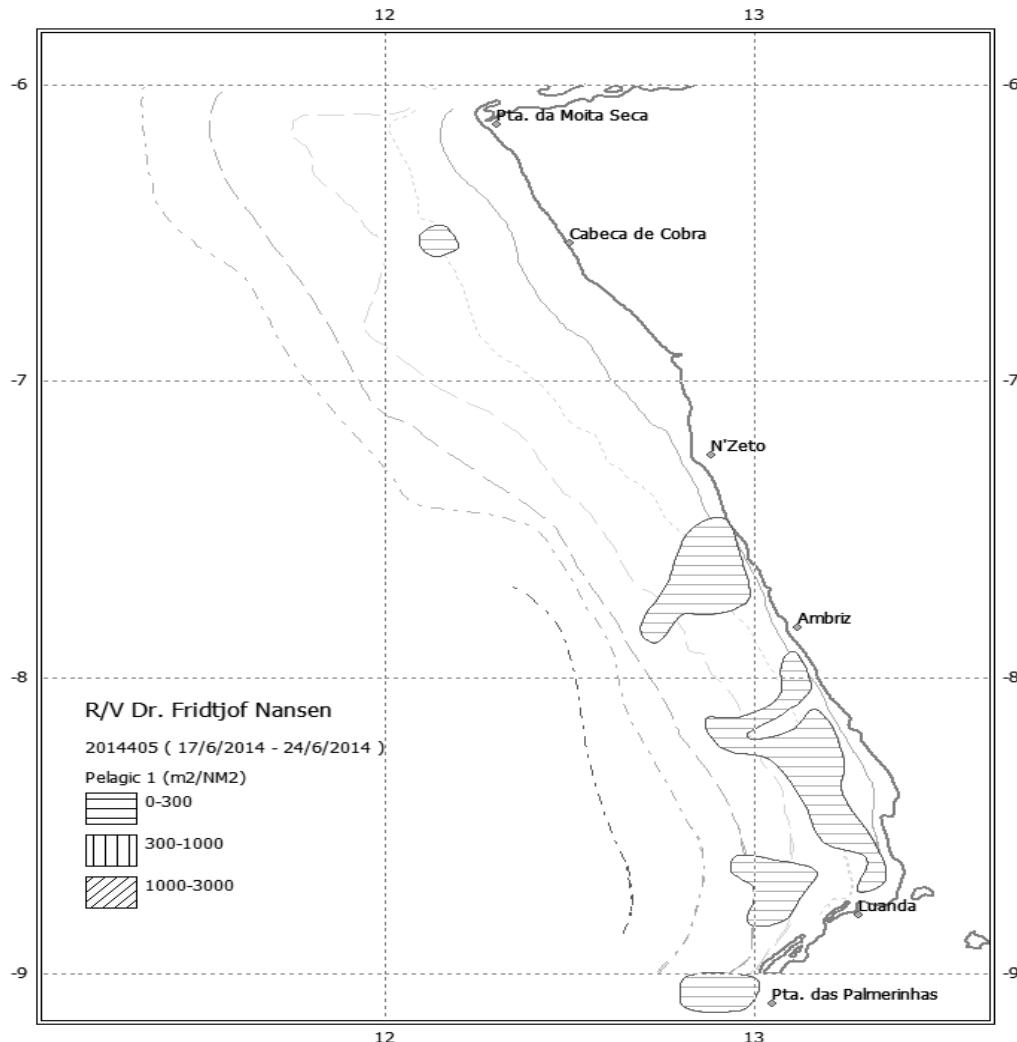

Figure 21. Distribution of Pelagic 1, Congo River-Pta. das Palmerinhas. Depth contours at 20, 50, 100, 200 and 500m.

The length distribution of the *Ilisha Africana* showed two modal peaks around 6 and 17 cm TL (Figure 22). The biomass of *Ilisha africana* in the northern area, based on the length distribution presented in Figure 22, was estimated to be 12 000 tonnes.

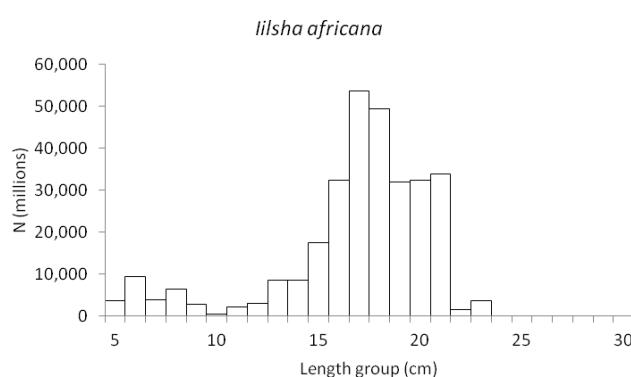

Figure 22. Total length distribution of *Ilisha africana*, Congo River-Pta. das Palmerinhas.

4.1.4 Pelagic species Group 2

This year the dominant species belonged to the Carangidae, *Chloroscombrus chrysuru* and *Selene dorsalis*. *Trichiurus lepturus* was also found in most of the trawl stations. The main acoustic registrations were found in two areas offshore Ponta da Moita Seca, being one of the areas with medium ($301 < S_A < 1000 \text{ m}^2/\text{NM}^2$) and high concentrations ($1001 < S_A < 3000 \text{ m}^2/\text{NM}^2$).

This group distributed continuously, in low densities ($0 < S_A < 300 \text{ m}^2/\text{NM}^2$), from Pta. da Moita Seca to Pta. das Palmerinhas (Figure 23).

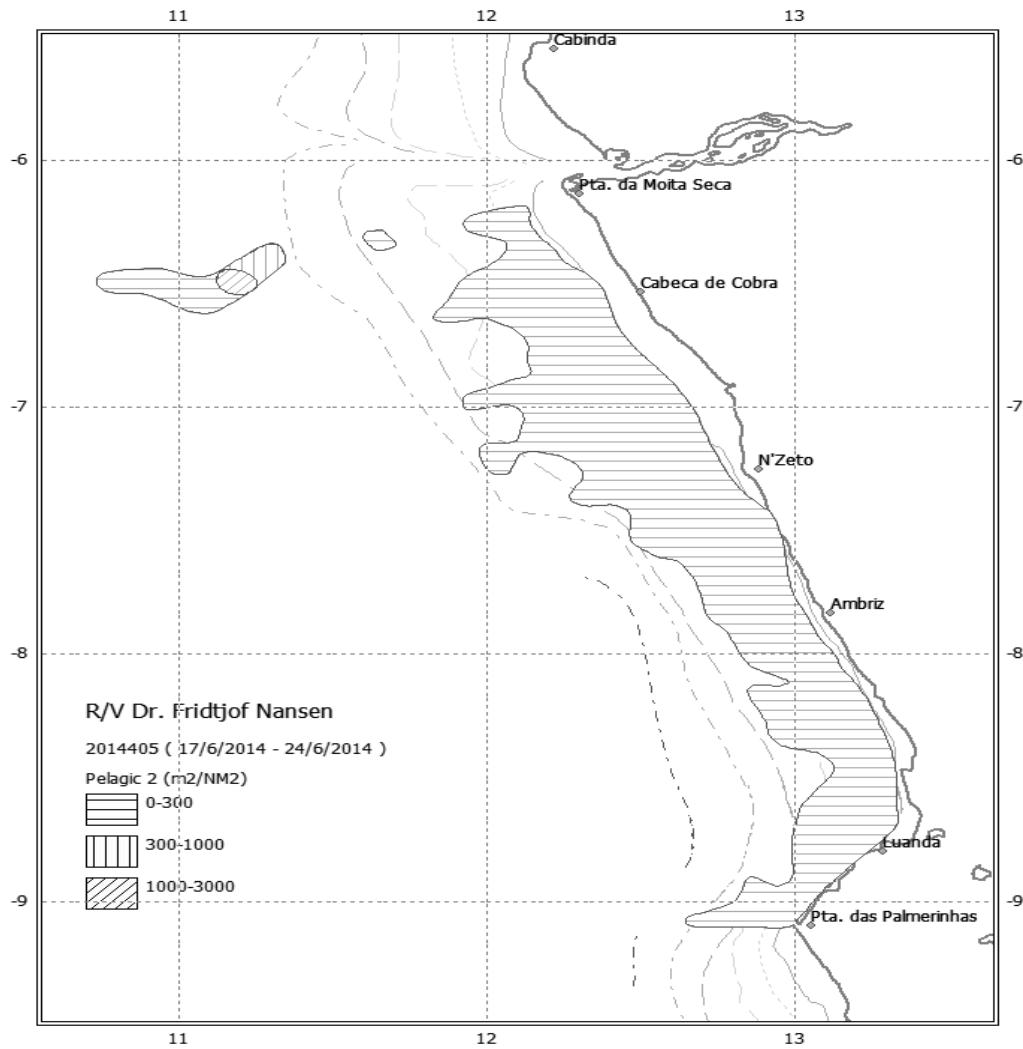

Figure 23. Distribution of Pelagic 2, Congo River-Pta. das Palmerinhas. Depth contours at 20, 50, 100, 200 and 500m.

The biomass calculation was based on an assumed average fish size of 30 cm and average condition factor of 1.0 and was estimated to be 77 379 tonnes. Further comments regarding the use of assumptions relating to average size and implications for potential bias (varying over time) will be given in chapter 5.3.

Table 3 shows the summary of the estimated abundance of main commercial species or species groups in northern region.

Table 3. Estimated abundance of pelagic fish, Congo River– Pta. das Palmerinhas.

Sardinella maderensis	Sardinella aurita	Trachurus trecae	Pelagic 1	Pelagic 2
124 380	15 828	862	12 000	77 379

4.2 Pta. das Palmerinhas - Benguela

4.2.1 Sardinella

In the central area *Sardinella* was distributed continuously along the coast. Over most of the area, low ($1 < s_A < 300 \text{ m}^2/\text{NM}^2$) and medium ($301 < s_A < 1000 \text{ m}^2/\text{NM}^2$) densities of *Sardinella* was observed. Additionally, several small areas with high ($1001 < s_A < 3000 \text{ m}^2/\text{NM}^2$) densities of sardinella were observed along the coast (Figure 24). Mostly small fish (<10 cm length), from both *Sardinella* species, were found in the coastal waters from 20-50 meters.

Sardinella was observed in the upper layer of the water column, schooling near the surface during daytime. During the day was not possible to trawl on *Sardinella* schools due to trawl avoidance. This is to some extent limiting the ability to observe size composition, especially in the areas with the shortest transects.

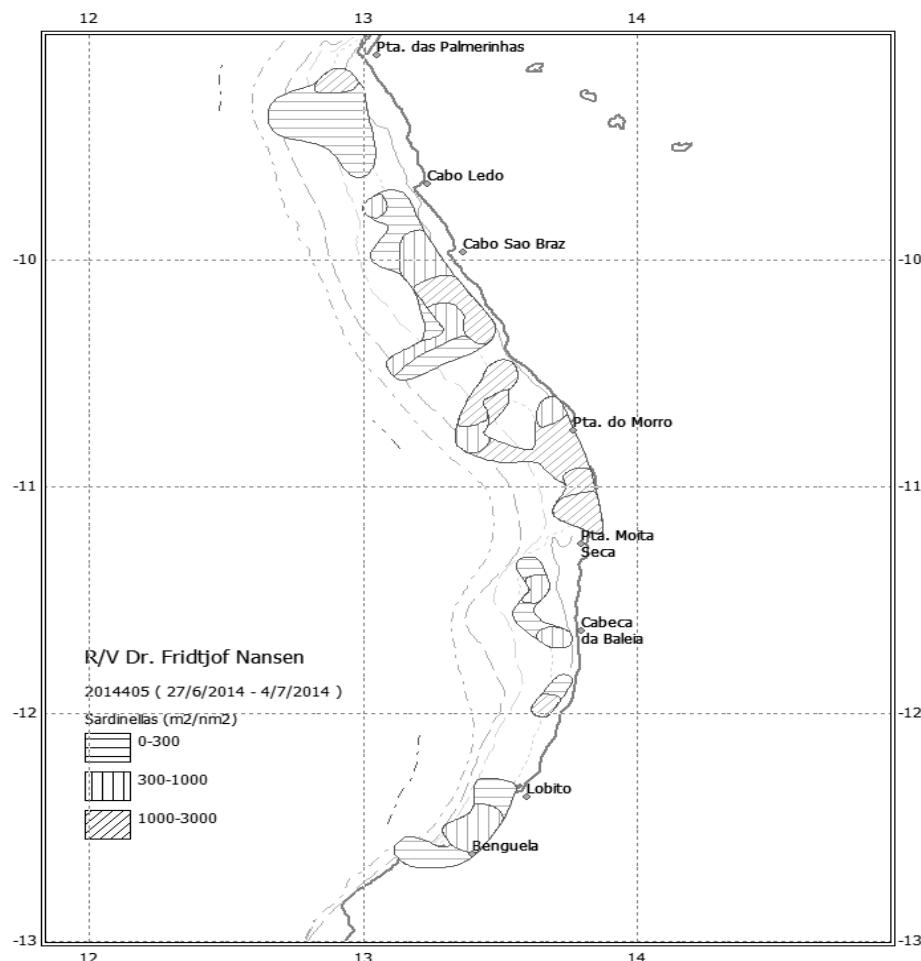

Figure 24. Distribution of *Sardinella* spp. Pta. das Palmerinhas- Benguela. Depth contours at 20, 50, 100 and 200 m.

The length distribution of *S. maderensis* showed four cohorts, peaking at 10, 14, 23 and 30 cm, while *S. aurita* showing three peaks at 7, 18 and 26 cm (Figure 25). Both species was distributed along the central area of the Angolan coast.

The total biomass for both species of sardinella was estimated at 272 069 tonnes. Of this 91 584 was allocated for *S. aurita* and 180 485 was *S. maderensis*.

This year's estimated biomass, was 8% less than the estimated biomass for 2013 (295 thousand tons) and 9% higher than the estimated biomass in the 2014 summer season (247 mil tonnes).

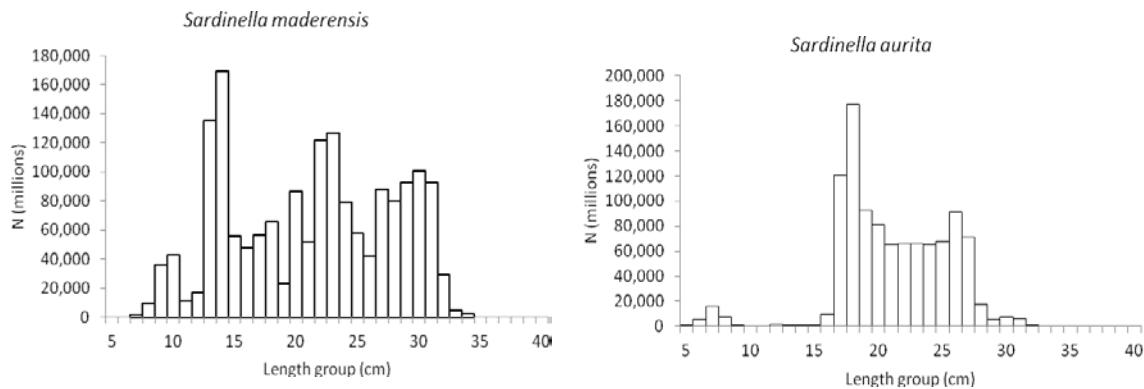

Figure 25. Total length distribution of *S. maderensis* and *S. aurita*. Pta. das Palmeirinhas - Benguela.

4.2.2 Horse mackerel

Cunene horse mackerel, *Trachurus trecae*, was found in the Angolan central region. *T. trecae* distributed in patches, of low densities ($0 < s_A < 300 \text{ m}^2/\text{NM}^2$), from Pta. das Palmeirinhas and Southern Benguela. Its distribution ranged from, approximately, 20 to 150 m depth bottom (Figure 26).

The biomass of Cunene horse mackerel was estimated at 24 mil tonnes. This biomass in this region was 79% less compared to 2013 (117 mil tonnes), in the same season, and 31% lower than the biomass estimated in the summer season this year (77 mil tonnes).

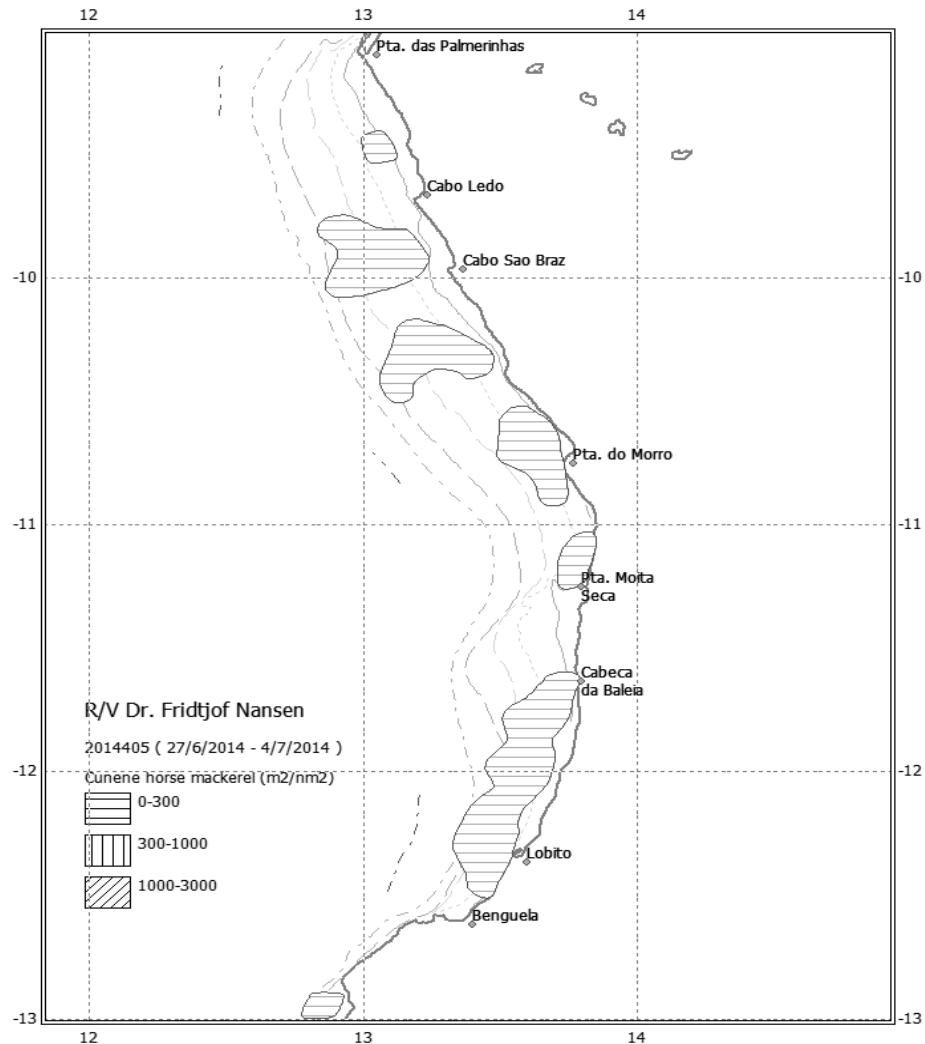

Figure 26. Distribution of horse mackerel (*Trachurus trecae*). Pta. das Palmeirinhas- Benguela. Depth contours at 20, 50, 100, 200 and 500 m.

The length frequency distribution is shown in Figure 27. The length frequency ranged between 13 and 47 cm with a well-defined peak at 19 cm. 48% of the biomass estimated comprised of fish <21 cm length.

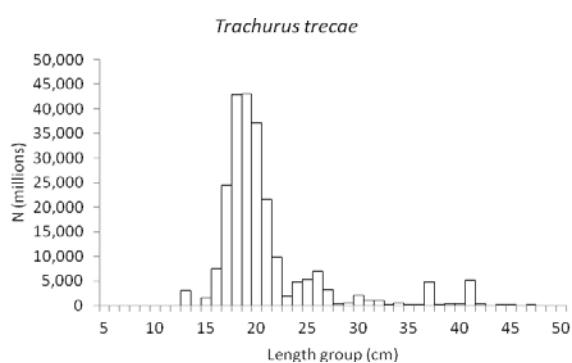

Figure 27. Total length distribution of horse mackerel (*Trachurus trecae*), Pta. das Palmeirinhas- Benguela.

In the central region, biological sampling was conducted on a total of 396 fishes. From these, 71.46 % were immature; among these individuals, 38.38 % female and 33 % male, from the stages I and II mostly. The mature individuals comprised 28.5 %, from which 15.4 % were females and 13.1 % males. These were mainly in stage IV. Post-spawning individuals consisted mainly of females, however they were found in low numbers (Figure 28). The length at 50% maturity was 24 cm.

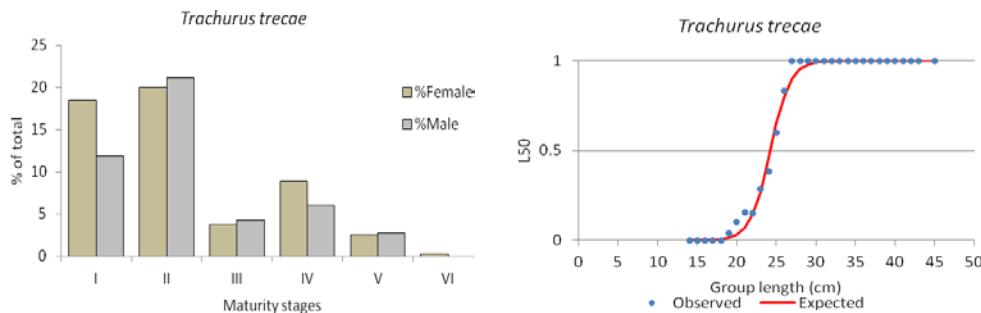

Figure 28. Maturity stages by sex and first length at maturity for *Trachurus trecae* in the Central region.

4.2.3 Pelagic species Group 1

In the central area, two species were found belonging to this group: *Ilisha africana* and *Engraulis encrasicolus*. However, *I.africana* dominated the catches and *E. encrasicolus* was only captured in one trawl catch (small quantity). Therefore, results presented mostly represent *I.africana*.

Pelagic fish in low densities ($0 < S_A < 300 \text{ m}^2/\text{NM}^2$) distributed sparsly from Pta. das Palmeirinhas to Benguela, while medium densities ($300 < S_A < 1000 \text{ m}^2/\text{NM}^2$) were only found in a small area, south from Cabo Sao Braz (Figure 29).

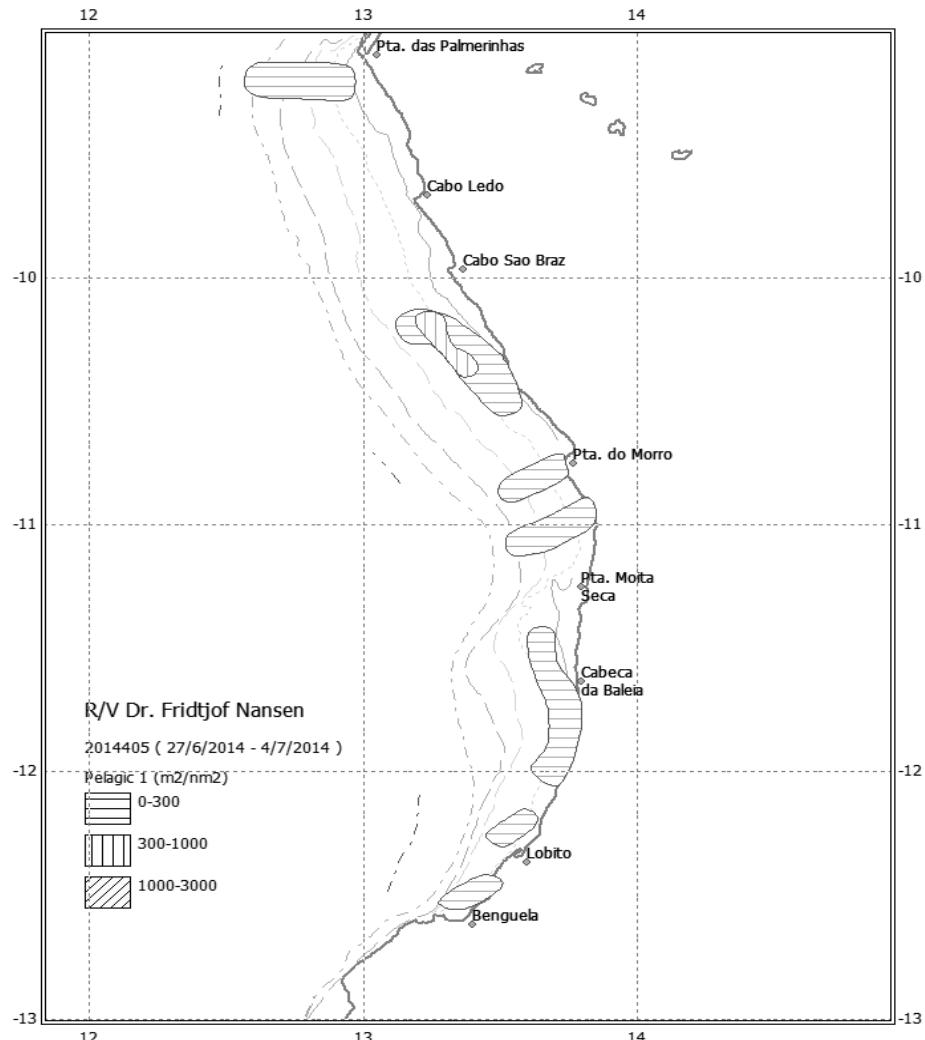

Figure 29. Distribution of pelagic species, group 1. Pta. das Palmerinhas- Benguela. Depth contours at 20, 50, 100, 200 and 500 m.

Length distribution from *I. africana* varied between 7 and 25 cm, with two peaks at 9 and 16 cm (Figure 30).

The biomass estimated in the central area was 17 103 tonnes.

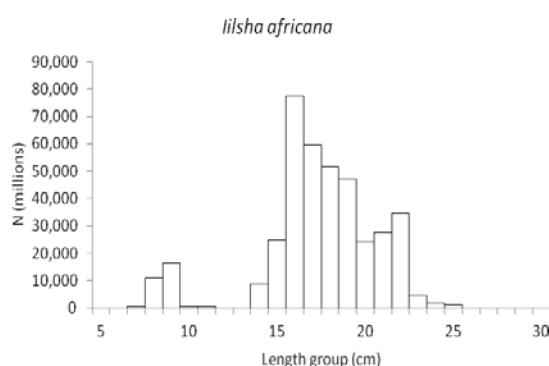

Figure 30. Total length distribution of mostly *Ilsha africana* and some few *Engraulis encrasicolus*, Pta. das Palmerinhas- Benguela.

4.2.4 Pelagic species Group 2

This group was found in two main areas but distributed along the coast, with low densities ($0 < s_A < 300 \text{ m}^2/\text{NM}^2$) (Figure 31). The most common species, from this group, caught in the trawl were Carangids: *Chloroscombrus chrysurus*, *Selene dorsalis*, *Caranx rhoncus* and other species as *Trachurus lepturus*, *Scomber japonicus* and *Sphyraena sp.*

The biomass estimate, was 55 193 tonnes, based on an average length of 30 cm. Additional comments regarding potential sources of bias related to this method is given in chapter 5.3.

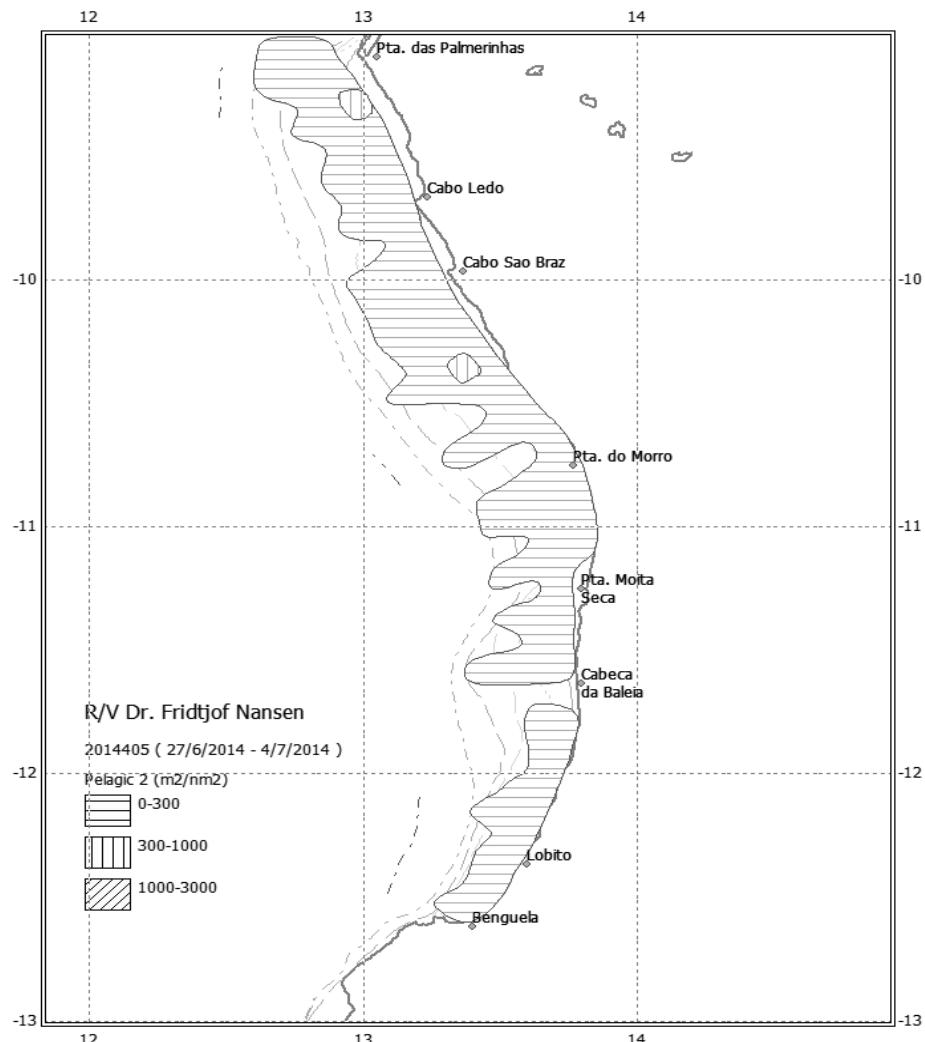

Figure 31. Distribution of pelagic species, group 2. Pta. das Palmeirinhas- Benguela. Depth contours at 20, 50, 100, 200 and 500 m.

Table 4 shows the summary of the abundance estimated of main commercial species in central region.

Table 4. Estimated abundance of pelagic fish (tonnes), Pta. das Palmeirinhas-Benguela.

Sardinella maderensis	Sardinella aurita	Trachurus trecae	Pelagic 1	Pelagic 2
180 485	91 584	23 915	17 103	55 193

4.3 Benguela - Cunene

4.3.1 Sardinella

Both species of Sardinella (*S. aurita* and *S. maderensis*) were found in the coastal waters from Cabo de Santa Marta to Namibe in small areas, with low density ($0 < s_A < 300 \text{ m}^2/\text{NM}^2$). The small area of medium fish density was found in the north of Tombwa ($300 < s_A < 1000 \text{ m}^2/\text{NM}^2$) (Figure 32).

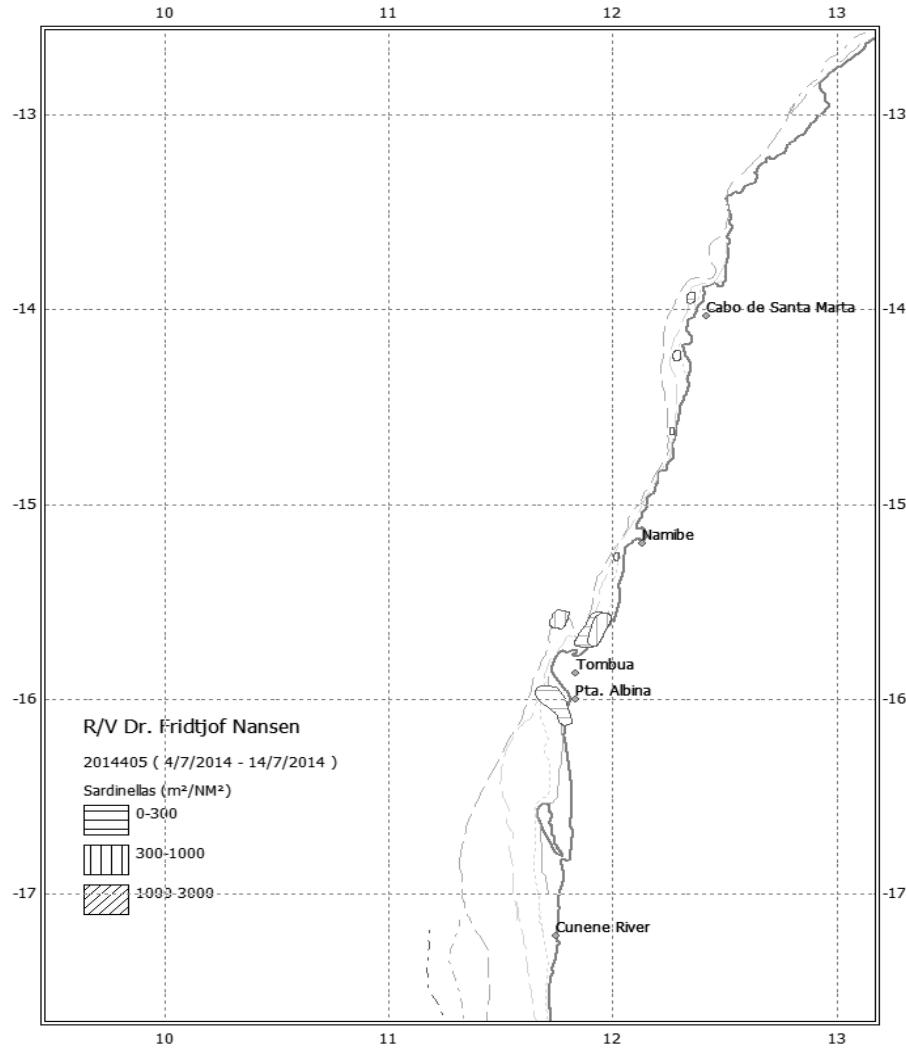

Figure 32. Distribution of *Sardinella aurita* and *S. maderensis*. Benguela–Cunene. Depth contours at 10, 20, 50, 100, 200 and 500 m.

Figure 33 shows the distribution of the length frequencies of both sardinellas. The juvenile of *S. maderensis* was found in the northern parts of the southern region. Length distribution of *S. maderensis* shows two cohorts. Juvenile with peaks at 13 cm and adult at 32 cm. The distribution of *S. aurita* shows two modal peaks at 18 and 22.

The total biomass for both species of sardinella was estimated at 14 314 tonnes. The biomass estimated this year is slightly higher than the winter 2013 estimate (10 thousand tonnes) and 45% less than estimated in summer 2014 (31 thousand tonnes). The *S. aurita* dominated (88%) in the southern region, and their biomass was 12 634 tonnes, while the biomass of *S. maderensis* was only 1 680 tonnes. The low biomass of *S. maderensis* in the region may be due to distributional shifts caused by the Angola-Benguela front.

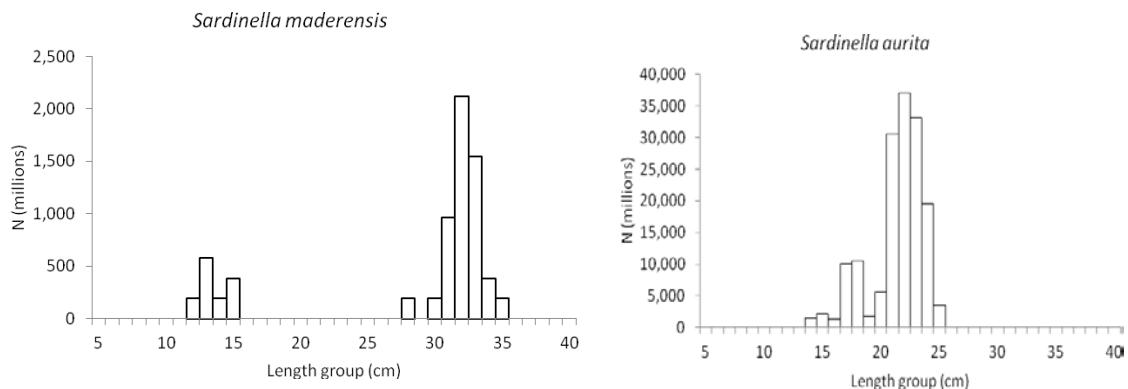

Figure 33. Total length distributions of *S. maderensis* and *S. aurita* in the Benguela-Cunene River.

4.3.2 Horse mackerel

Both species of horse mackerel, the Cunene horse mackerel (*Trachurus trecae*) and the Cape horse mackerel (*Trachurus capensis*) were found in southern region and had a continuous distribution (Figure 34). North of Namibe we found only *Trachurus trecae* at low density values ($0 < s_A < 300 \text{ m}^2/\text{NM}^2$) while both species were found in a mix between Namibe and Cunene River at considerable higher densities and amounts. We observed large areas of both medium ($300 < s_A < 1000 \text{ m}^2/\text{NM}^2$) and high densities ($1000 < s_A < 3000 \text{ m}^2/\text{NM}^2$).

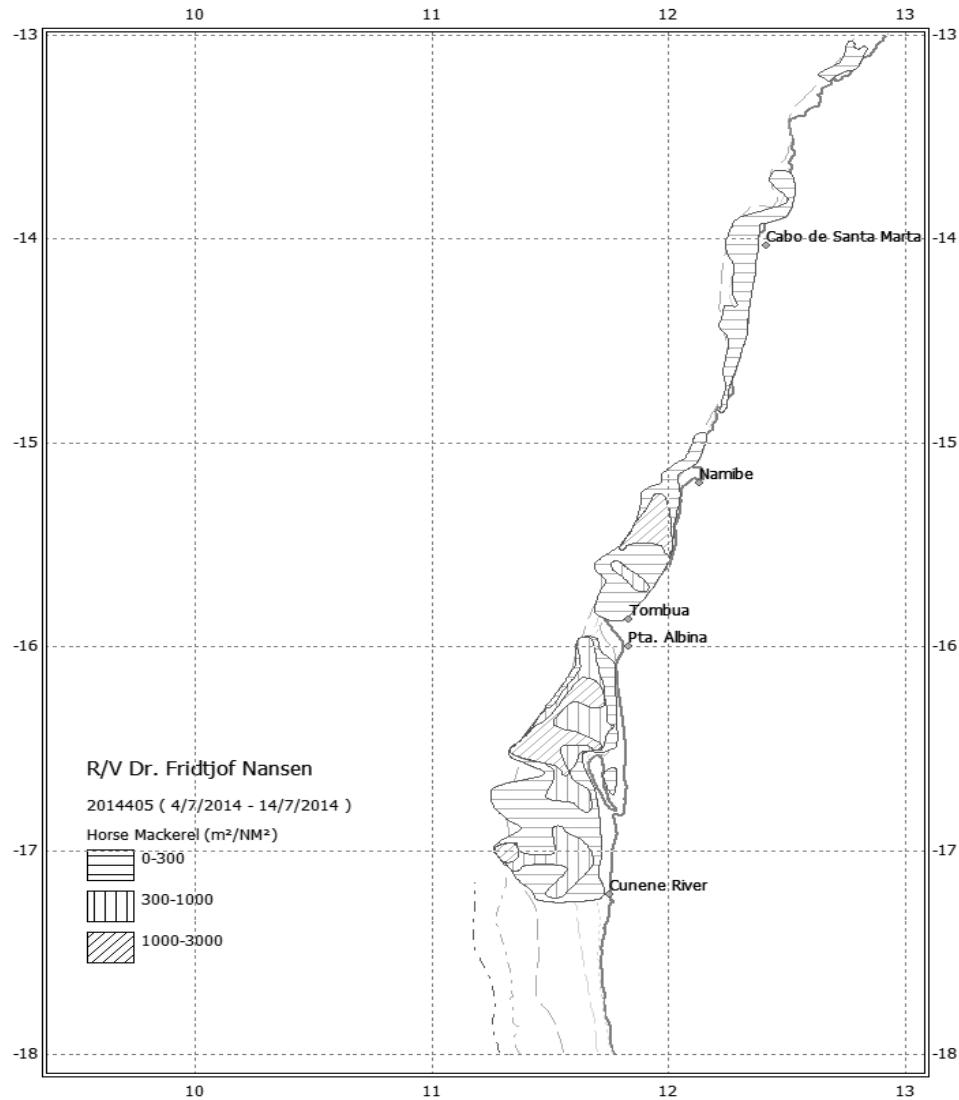

Figure 34. Distribution of horse mackerel (both species). Benguela–Cunene. Depth contours at 10, 20, 50, 100, 200 and 500 m.

Figure 35 shows the length frequency distributions of the Cunene and Cape horse mackerels, respectively. Cunene horse mackerel has a mode, peaking at about 16 cm TL. Cape horse mackerel shows three modes at around 10, 15 and 36 cm TL.

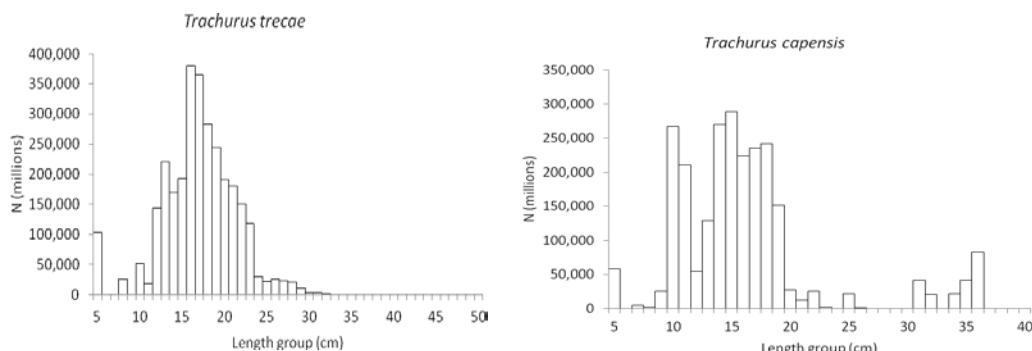

Figure 35. Total length distributions of *Trachurus trecae* and *T. capensis* Benguela–Cunene.

The biomass estimated for both horse mackerel species in the region, was 297 833 tonnes, while 54% for Cunene horse mackerel and 46% for Cape horse mackerel. Juveniles dominate the estimate in numbers for both species, but is just below half of the biomass (48% of biomass from fish <21cm TL).

In 801 biological samples from the south area, 45% were female, 41% male and 14% indeterminate. 16% of the fish were found to be mature, 84 were immature. The majority of the fish were found in stage I and II for female and males. The length at 50% maturity of *Trachurus trecae*, of this region, was 25 cm TL (Figure 36).

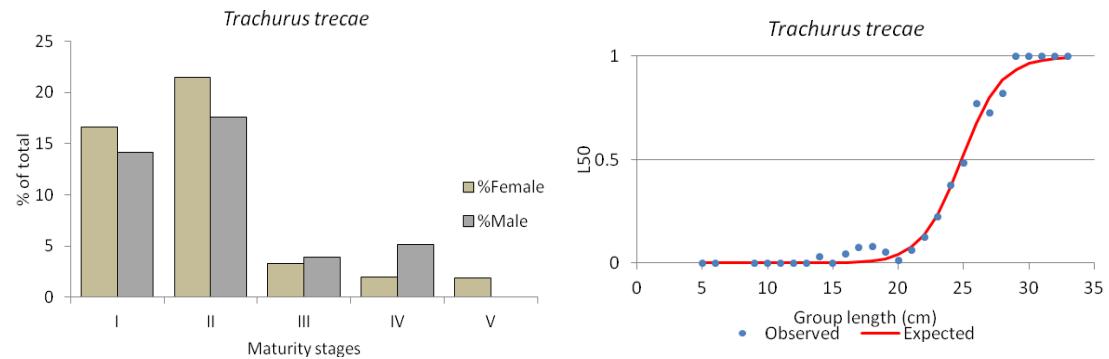

Figure 36. Maturity stages by sex and first length at maturity for *Trachurus trecae* in the South region.

4.3.3 Pelagic species Group I

The dominant species belonging to this group were round herring (*Etrumeus whiteheadi*) and anchovy (*Engraulis encrasicolus*). They were found in the area between Namibe and Cunene River of low densities areas ($0 < s_A < 300 \text{ m}^2/\text{NM}^2$), (Figure 37).

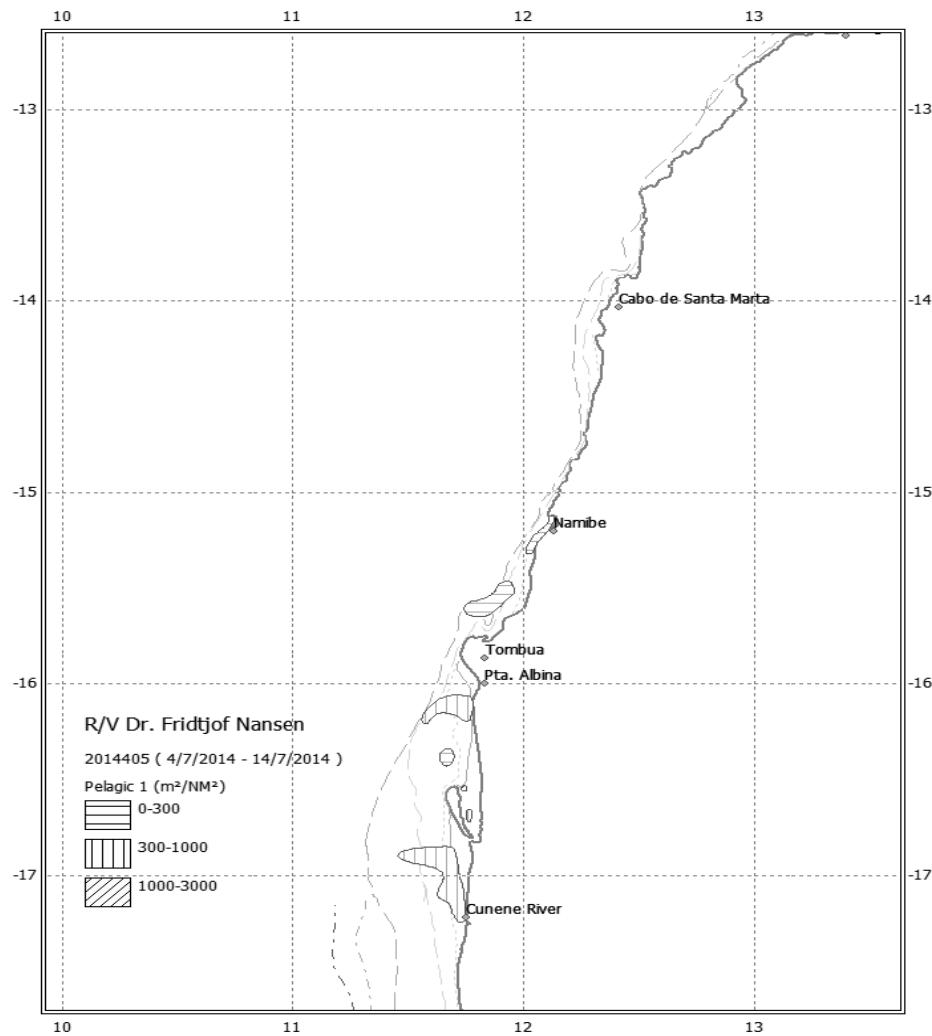

Figure 37. Distribution of Pelagic 1. Benguela–Cunene. Depth contours at 10, 20, 50, 100, 200 and 500 meters.

The biomass for this group was estimated to be 15 883 tonnes mostly *Etrumeus whiteheadi* and *Engraulis encrasicolus* were caught at only one trawl station. The length distribution of *Etrumeus whiteheadi* has three modes at around 10, 13 and 16 cm TL (Figure 38) and was used as basis for the biomass estimate together with an observed length-weight relationship.

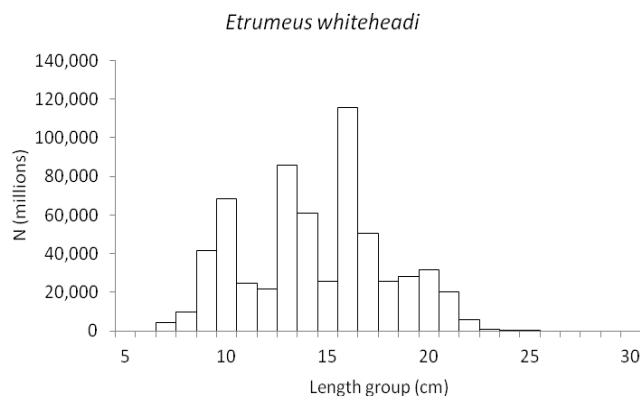

Figure 38. Total length distribution of *Etrumeus whiteheadi*, Benguela–Cunene.

4.3.4 Pelagic species Group 2

This group was found distributed along the coast between Cabo de Santa Marta and Cunene in patched area with low densities areas ($0 < s_A < 300 \text{ m}^2/\text{NM}^2$) (Figure 36). The group was dominated by Carangids and other species as *Trachurus lepturus*, *Scomber japonicus* and *Sphyraena sp..*

The biomass estimated was 18 541 tonnes, based on an average length of 30 cm TL. See also subsection 5.3 regarding assumptions and possible sources of bias.

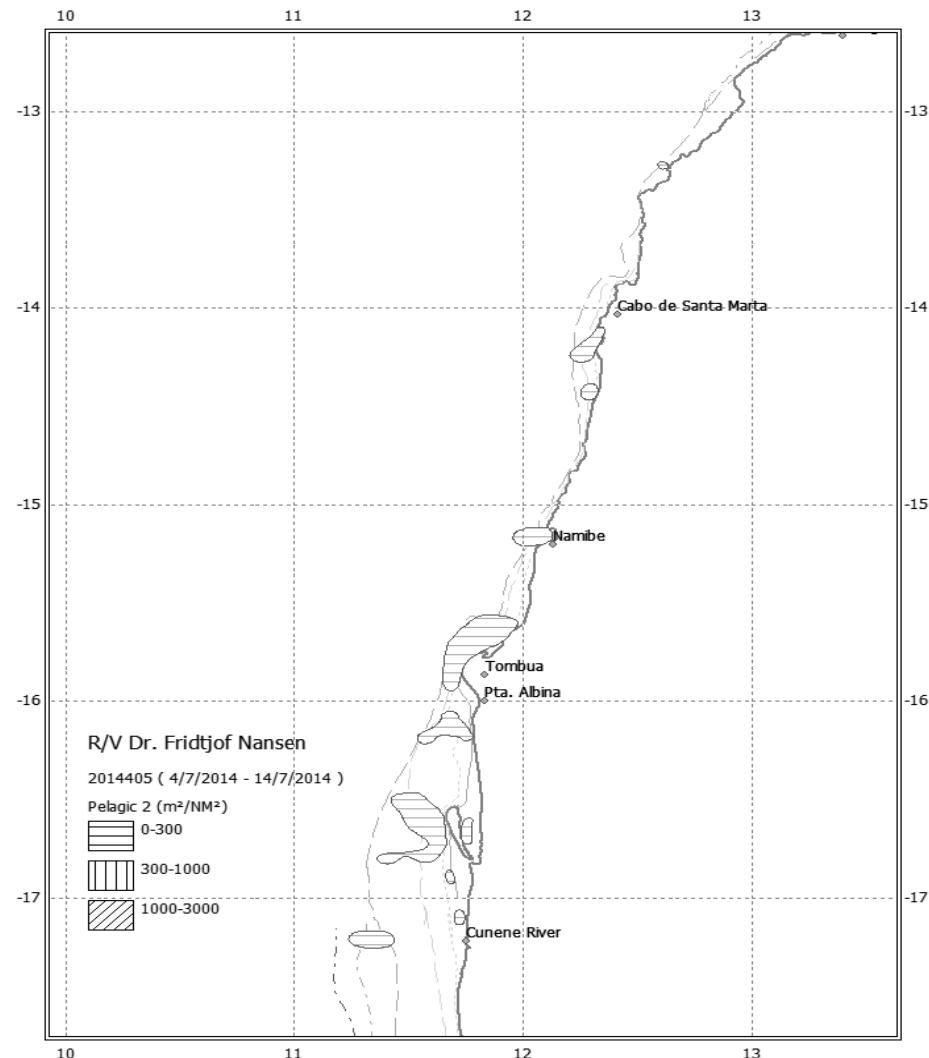

Figure 39. Distribution of Pelagic 2. Benguela–Cunene. Depth contours at 10, 20, 50, 100, 200 and 500 meters.

Table 5 shows the summary of the abundance estimated of main commercial species in the southern region.

Table 5. Estimated abundance of pelagic fish (tonnes), Benguela-Cunene (1000 tonnes).

Sardinella maderensis	Sardinella aurita	Trachurus trecae	Trachurus capensis	Pelagic 1	Pelagic 2
1 680	12 634	161 187	136 646	15 883	18 541

CHAPTER 5 SUMMARY OF SURVEY RESULTS

5.1 Sardinella

The estimated biomass of sardinella shows a cyclic fluctuating pattern throughout the time series (Figure 40). This is commonly found in pelagic species, usually reflecting actual changes in abundance but also variation in the availability of the surveyed populations, often caused by changes in the environmental conditions. On the overall, the Sardinella stocks presently seem to be in relatively good condition. The total biomass estimate for sardinellas was 426 591 tonnes. This is at the same level as the winter 2013 survey (422 000 tonnes) and higher than in the summer 2014 (363 000 tonnes).

The length/size composition for both species shows highest abundance (in numbers) of size groups (15-20 cm) soon entering the fishery. The estimated numbers for the lowest size range below 10 cm is somewhat higher than what is usually observed during this survey, but estimates are more uncertain and the survey coverage must be assumed to be poor for these size groups often found in more shallow waters than the survey covers.

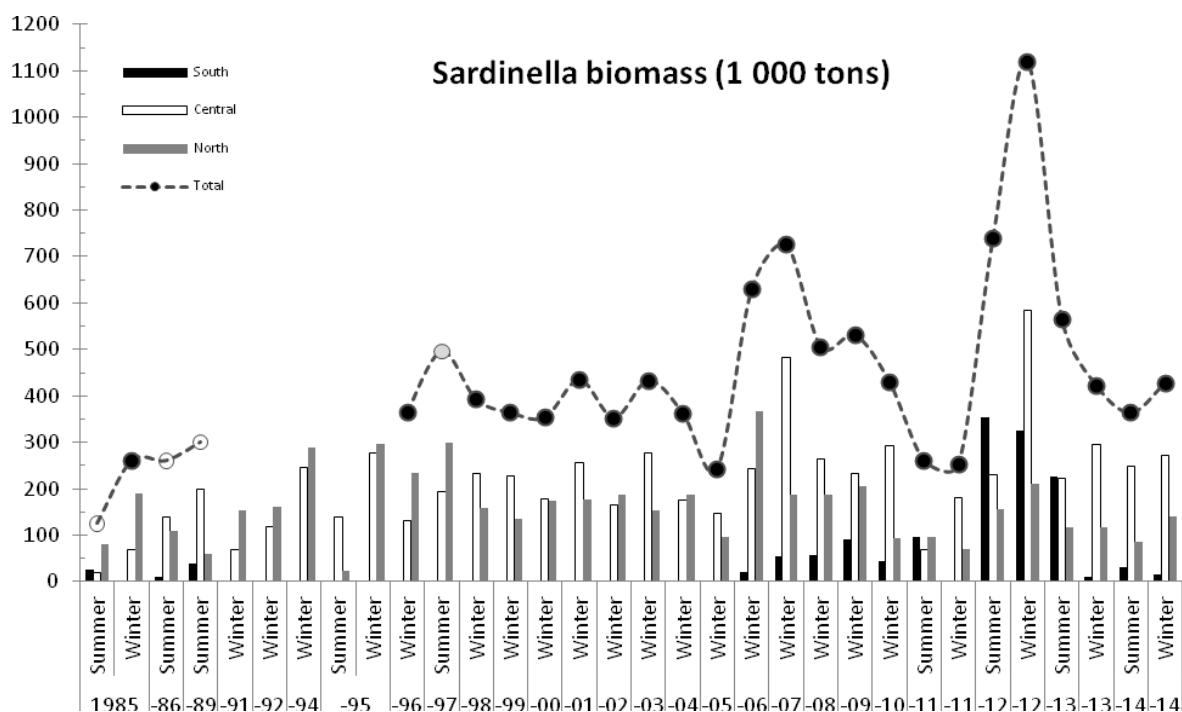

Figure 40. Biomass estimates of Sardinella by regions and surveys (1 000 tonnes).

The overall length frequency distributions of the two Sardinella species show both juvenile and adult cohorts (Figure 41). The distribution of *S. maderensis* shows well-defined cohorts with modal peaks around 10, 16 and 27 cm total length. For *S. aurita*, the distribution shows modal peaks at 7, 18 and 26 cm TL.

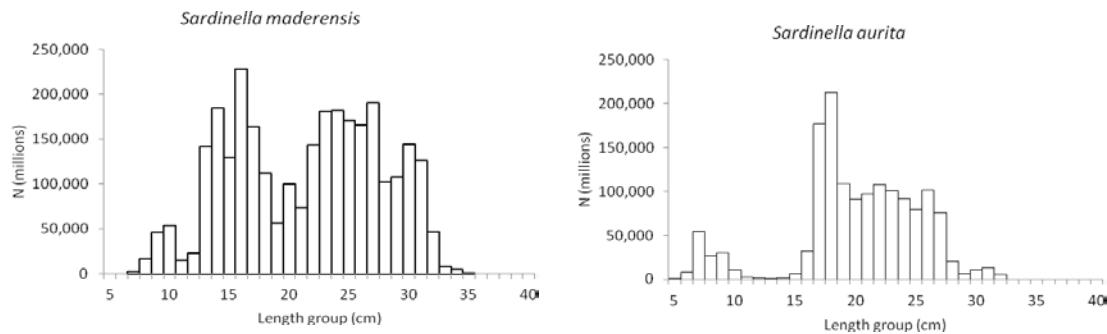

Figure 41. Overall total length distribution of *S. maderensis* and *S. aurita*.

5.2 Horse mackerel

The total biomass of Cunene horse mackerel was estimated at 185 964 tons (Figure 42). This is less than winter 2013 (257 000 tons) and summer 2014 (295 000) estimates, and less than long term mean (2000-2014) of 226 000 tons. The bulk of the biomass is found in the southern region which is similar to other years except last year when the biomass was centered in the central region. The most abundant size group ranges from 15-20cm and will soon recruit to the fishery. There is a marked lack of Cunene horse mackerel > 30cm in the survey results. We would like to point to three possible causes for this:

- The survey coverage has certain limitations and both an offshore as well as an inshore component may be outside the survey area.
- Larger horse mackerel have a higher swimming capacity and may have higher avoidance to the sampling trawls used. Such gear avoidance may differ between years due to differences in environmental conditions like feeding conditions. This can also be linked due to changes in diurnal behavioural patterns like depth preferences.
- The fishing activity is primarily targeting large sized horse mackerel.

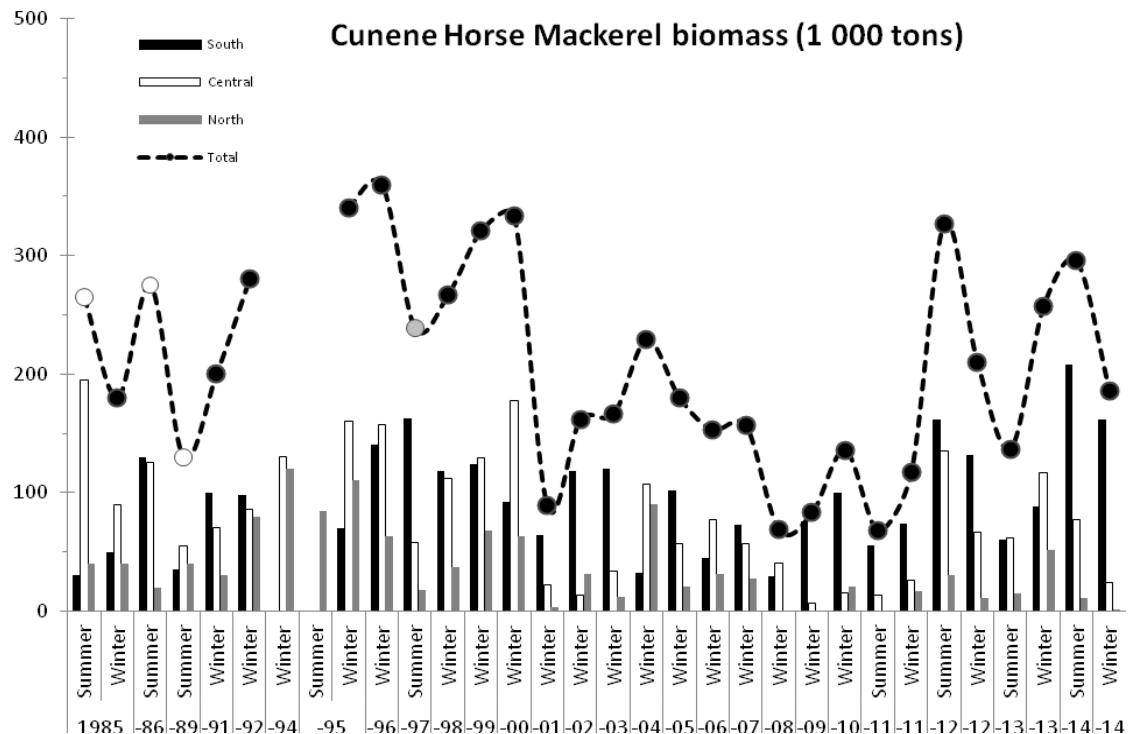

Figure 42. Biomass estimates of Cunene horse mackerel by regions and surveys (1 000 tonnes).

The overall length frequency distributions of the horse mackerel species include juvenile cohorts for both *T. Trecae* and *T. capensis* (Figure 43). The distribution of *T. trecae* shows well-defined cohorts with modal peaks around 5, and 17 cm total length. For *T. capensis*, the distribution shows modal peaks at 5, 10, 15, 17 and 36 cm TL.

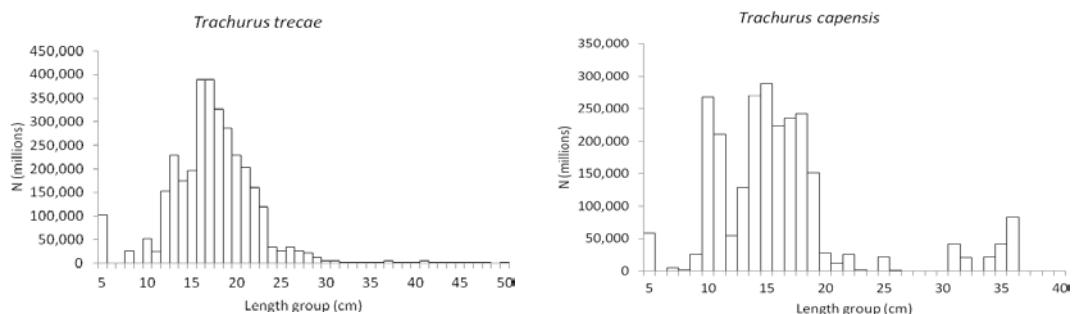

Figure 43. Overall total length distribution of *T. trecae* and *T. capensis*.

The total biomass of Cape horse mackerel was estimated at 136 646 tonnes. This is considerably higher than found in previous surveys in the winter 2013 (123 000 tonnes) and in the summer 2014 (66 757 tonnes). The result for Cape horse mackerel should not be interpreted as an increase in stock size since such an increase can be caused by distributional shifts. More thorough analysis would be needed including survey information from Namibian waters. The possible shift in distribution (also observed for Cunene horse mackerel last year) may be linked to the position of the Angolan-Benguela front (ABF) and corresponding upwelling influencing the availability of horse mackerel to the survey.

5.3 Regarding simplified biomass estimation

Estimates of species groups (pelagic 1 and pelagic 2) are based on less detailed sampling than sardinellas and horse mackerels. This year the pelagic 1 group was dominated by single species (in their respective regions, *Ilisha africana* in the northern and central regions and *Etrumeus whiteheadi* in the southern region of the survey area) and the biomass estimate corresponds to this single species with a small proportion added. Pelagic 1 species are usually found very close to the surface and the proportion of biomass found above the acoustic range may be considerable. This is a known source of bias and it is not known if this bias varies between years/seasons.

Pelagic 2 species are estimated assuming a fixed length and a mean condition factor. This practice introduces two potential sources of bias:

Conversion of echo abundance to number of fish depends on the average of squared lengths and this will change between years. This is a source of bias in the estimation of numbers of fish. Different length distributions may produce the same average squared length, but the corresponding biomass will be different.

Due to these bias issues overinterpretation of time series of pelagic 2 biomass estimates should be avoided.

5.4 Summary

A summary of main findings are presented in Table 6. The reported biomass levels should be viewed with considerable caution. The estimates are relative indices rather than absolute estimates of abundance, and the cyclic variation pattern for sardinellas and horse mackerels may be accentuated by changes in distributional behaviour related to the environmental conditions. This variation is particularly evident in the Benguela Current frontal zone in the Southern region, where the cold Benguela meets the warm, subtropical Angola current.

Observed variation in biomass may also be caused by favourable conditions increasing the availability to fishing gear. Increased availability does not necessarily mean increased abundance, sometimes availability may even increase with decreasing abundance. Continuing to fish on the basis of high availability therefore involves risk. It is particularly evident for Cunene horse mackerel confined to the Southern region and with the biomass in this region is comprised by juveniles (TL < 18 cm).

Other biological references also clearly indicate that the Cunene horse mackerel stock is still under considerable pressure. From the reference year 1996, the length distributions have been shifting towards smaller fish, indicating high fishing pressure on the adult stock (Figure 43).

In this situation, increasing fishing pressure could involve a high risk for failure of the long-term recovery of the Cunene horse mackerel stock.

Table 6. Estimated abundance of pelagic fish (tonnes), Angolan coast Congo River-Cunene.

Species	North	Central	South	Total

ANNEX II. Length frequencies of pelagic 2

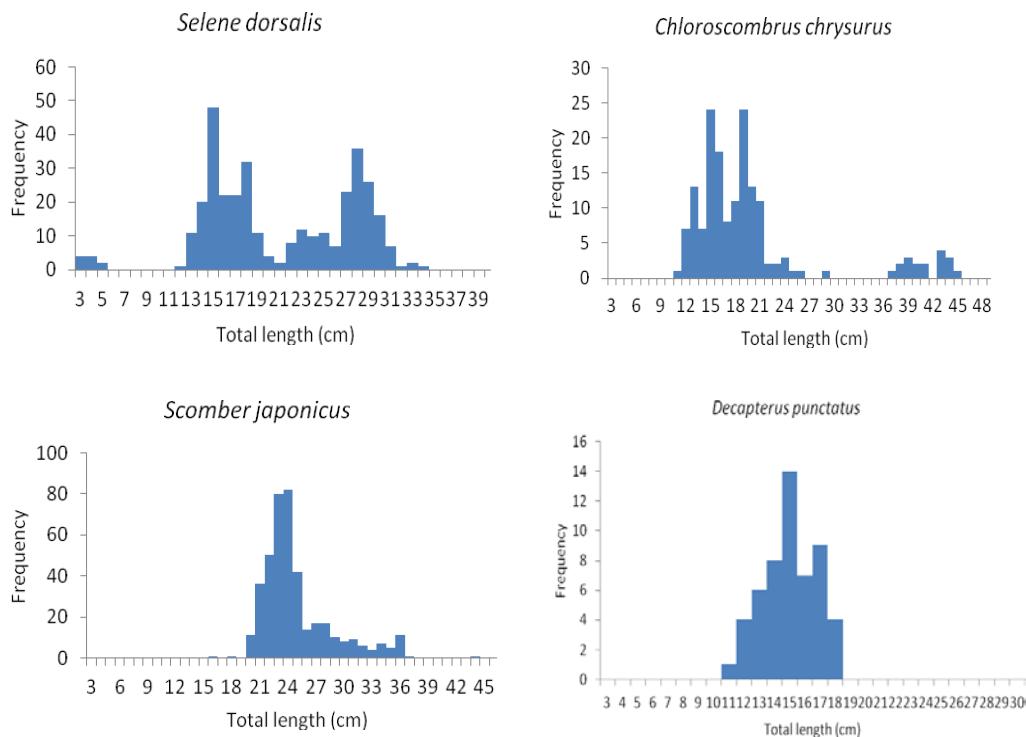

Figure 44 - Length frequencies of pelagic 2 species.

ANNEX III. Maturity stages for horse mackerel and sardinella

Table 7. Maturity stages for horse mackerel and sardinella

Stage	Maturity stage	Description
I	Immature	Small gonads, do not occupy more than 1/3 of abdominal cavity length. Ovary pinkish; testis whitish. Ovary not visible to naked eye
II	Maturing virgin and recovering spent	The gonads begin to develop, increasing substantially in size; about ½ length of the abdominal cavity. Gonads more opaque, small points visible to the naked eye (oocytes at the beginning of vitelogenese). The gonads in rest/recovery more flaccid with some more conspicuous blood than the gonads in development.
III	Mature. Before pre-spawning	At the beginning, oocytes more conspicuous giving the gonad a granular aspect. Ovary yellow-orange, testis creamy. Visible sperm in testis if open. Gonads quite swollen in the beginning of the reproduction period. Gonads that have spawned once lose consistency, but opaque oocytes present, and sperm in testis if cut. At the end of the stage is possible to find some translucent oocytes. Gonads occupy about 2/3 of abdominal cavity.
IV	Mature Pre-spawning	The gonads occupy about 2/3 of abdominal cavity. Ovaries orange in colour with visible blood vessels. Most oocytes translucent, testis creamy, flat and brilliant texture. The gonads stop flowing oocytes and sperm flows at low pressure.
V	Mature. In spawning	The gonads occupy about 2/3 or less of abdominal cavity. Ovaries orange in colour with the conspicuous blood vessels, blood stained mainly in one end. Most oocytes translucent; testis creamy, flat and brilliant texture. The gonads stop flowing oocytes and sperm flows at low pressure. Pink stains at the end of gonad.
VI	Post-spawning	The gonads decrease in size and occupy about ½ or less, of abdominal cavity. Gonads flaccid and bloody. Ovary can contain remaining oocytes that were not emitted. Testis may have sperm remaining in the seminal duct. Pinkish areas in the whole extension of the gonad.

ANNEX IV. Allocation of acoustic densities to species groups.

Note that for the groups such as sardinella, horse mackerel, big-eye grunt and pilchard all encountered species are listed, while only examples are listed for the remaining groups.

Table 8. Species groups used for the acoustic scrutinizing.

Group	Taxon	Species
Sardinella	Sardinella sp.	<i>S. aurita</i> <i>S. maderensis</i>
Horse mackerel	Trachurus sp.	<i>T. trecae</i> <i>T. trachurus capensis</i>
Pilchard	Sardinops	<i>S. ocellatus</i>
Big-eye grunt		<i>Brachydeuterus auritus</i>
Pelagic species 1	Clupeiformes ¹	<i>Ilisha africana</i> <i>Etrumeus whiteheadi</i> <i>Engraulis encrasiculus</i>
Pelagic species 2	Carangidae ²	<i>Selene dorsalis</i> <i>Chloroscombrus chrysurus</i> <i>Decapterus rhonchus</i> <i>Seriola carpenteri</i> Scombridae <i>Auxis thazard</i> <i>Sarda sarda</i> <i>Scomber japonicus</i> Sphyraenidae <i>Sphyraena guachancho</i> Others <i>Trichiurus lepturus</i> <i>Lepidopus caudatus</i>
Other demersal species	Sparidae ³	<i>Dentex angolensis</i> <i>D. macrophthalmus</i> <i>D. congoensis</i> <i>D. canariensis</i> <i>D. barnardi</i> <i>Pagellus bellottii</i> <i>Sparus caeruleostictus</i> <i>S. pagrus africanus</i> Other taxii <i>Saurida brasiliensis</i> <i>Arioma bondi</i> <i>Pomadasys incisus</i> <i>Galeoides decadactylus</i>
Mesopelagic species	Myctophidae ₃ Other mesopelagic fish	<i>Diaphus dumerili</i> <i>Trachinocephalus myops</i>
Plankton	Calanoidae Euphausiidae Other plankton	<i>Calanus sp.</i> <i>Meganyctiphanes sp.</i>

other than *Sardinops* sp.; ² other than *Trachurus* sp.; ³ main taxon in group.

ANNEX VI. Instruments and fishing gear used

The Simrad ER-60/18, 38, and 120 kHz scientific sounder was run during the survey for fish observation and bottom conditions. The 200 kHz was out of order at the start of the survey.

Standard sphere calibrations were carried out in Baía dos Elefantes 06.07.2013 using 64 and 60 mm diameter copper spheres and 38.1 mm tungsten carbide sphere for 18, 38 and 120 kHz, respectively. The details of the settings of the 38 kHz echo sounder where as follows:

Transceiver-2 menu (38 kHz)	
Transducer depth	5.50 m
Absorption coefficient (variable with conditions)	8.7 dB/km
Pulse length	medium (1,024ms)
Bandwidth	2.43 kHz
Max power	2000 Watt
2-way beam angle	-20.6dB
Gain	25.13 dB
SA correction	-0.55 dB
Angle sensitivity	21.9
3 dB beam width	7.01° along ship
6.98° athwart ship	
Along ship offset	0.12°
Athwart ship offset	0.02°
Bottom detection menu	
Minimum level	-45 dB

Fishing gear

The vessel has two different sized "Åkrahamn" pelagic trawls and one "Gisund super bottom trawl". Trawls were used for identification of acoustic targets only.

The bottom trawl has a headline of 31 m, footrope 47 m and 20 mm mesh size in the cod end with an inner net of 10 mm mesh size. The trawl height was about 4.5 m and distance between wings during towing about 21 m. The sweeps are 40 m long. The trawl is equipped with a 12" rubber bobbins gear. New doors are 'Thyborøn' combi type, 7.41 m², 1720 kg. These have been in use onboard since 19.02.08.

The SCANMAR system was used on all trawl hauls. This equipment consists of sensors, a hydrophone, a receiver, a display unit and a battery charger. Communication between sensors and ship is based on acoustic transmission. The doors are fitted with sensors to provide information on their distance, and the trawl was equipped with a trawl eye that provides information about the trawl opening. A catch sensor on the cod-end indicated the size of the catch.

ANNEX VII. Monitoring lines

ANGOLA MONITORING LINES, ANGOLA, updated winter 2013

Main Monitoring lines of highest priority (red): Multinet, bottles and CDT

Local monitoring lines (green) of next highest priority: Multinet, bottles and CDT

Standard Transect (yellow): CDT only

Table 11. Table showing the positions, type of sampling, sampling depths, and other details of Angolan monitoring lines.
