THE EAF-NANSEN PROGRAMME (2017–2021)

The EAF-Nansen Programme “Supporting the Application of the Ecosystem Approach to Fisheries Management considering Climate and Pollution Impacts” supports partner countries and regional organizations in Africa and the Bay of Bengal improving their capacity for the sustainable management of their fisheries and other uses of marine and coastal resources through the implementation of the Ecosystem Approach to Fisheries (EAF), taking into consideration the impacts of the climate and pollution.

The Programme is executed by the Food and Agriculture Organization of the United Nations (FAO) in close collaboration with the Institute of Marine Research (IMR) of Bergen, Norway, and funded by the Norwegian Agency for Development Cooperation (Norad). This Programme is the current phase (2017–2021) of the Nansen Programme which started in 1975.

The aim of the Programme is that sustainable fisheries improve food and nutrition security for people in partner countries. It builds on three pillars, Science, Fisheries Management, and Capacity Development, and supports partner countries to produce relevant and timely evidence-based advice for management, to manage fisheries according to the EAF principles and to further develop their human and organizational capacity to manage fisheries sustainably. In line with the EAF principles, the Programme adopts a broad scope, taking into consideration a wide range of impacts of human activities and natural processes on marine resources and ecosystems including fisheries, pollution, climate variability and change.

A new state of the art research vessel, the *Dr Fridtjof Nansen*, is an integral part of the Programme. A comprehensive science plan, covering a broad selection of research areas, and directed at producing knowledge for informing policy and management decisions, guides the Programme’s scientific work.

The Programme works in partnership with countries, regional organizations, other UN agencies as well as other partner projects and institutions.

LE PROGRAMME EAF-NANSEN (2017-2021)

Le programme EAF-Nansen « Soutenir l'application de l'approche écosystémique pour la gestion des pêches compte tenu des impacts du climat et de la pollution » appui les pays partenaires et les organisations régionales en Afrique et dans le golfe du Bengale pour améliorer leur capacité de gestion durable de leurs pêcheries et d'autres usages de la mer ainsi que les ressources côtières, grâce à la mise en œuvre de l'Approche écosystémique des pêches (AEP), en tenant compte des impacts du climat et de la pollution.

Le programme est exécuté par l'Organisation des Nations Unies pour l'alimentation et l'agriculture (FAO) en étroite collaboration avec l'Institut de recherche marine (IMR) de Bergen, en Norvège, et financé par l'Agence norvégienne de coopération au développement (Norad). Ce programme est la phase actuelle (2017-2021) du programme Nansen qui a débuté en 1975.

L'objectif du programme est que la pêche durable améliore la sécurité alimentaire et nutritionnelle des populations des pays partenaires. Il s'appuie sur trois piliers, la science, la gestion des pêches et le développement des capacités, et aide les pays partenaires à produire des avis pertinents et opportuns fondés sur des données factuelles pour la gestion, à gérer les pêcheries conformément aux principes de l'AEP et à développer davantage leur capacité humaine et organisationnelle à gérer durablement les pêches. Conformément aux principes de l'AEP, le programme adopte une large vision, prenant en considération un large éventail d'impacts des activités humaines et des processus naturels sur les ressources et les écosystèmes marins, y compris la pêche, la pollution, la variabilité et le changement climatique.

Un nouveau navire de recherche de pointe, le *Dr Fridtjof Nansen*, fait partie intégrante du programme. Un plan scientifique complet, couvrant un large éventail de domaines de recherche et visant à produire des connaissances pour éclairer les décisions de politique et de gestion, guide les travaux scientifiques du programme.

Le programme travaille en partenariat avec des pays, des organisations régionales, d'autres agences des Nations Unies ainsi que d'autres projets et institutions partenaires.

EXECUTIVE SUMMARY

The area surveyed in 2019 by the research vessel (R/V) *Dr Fridtjof Nansen* includes the continental shelf and upper slope of West Africa from South Africa to Morocco. Legs 2.2 and 2.4 covered the continental shelf and upper slope in Namibia between the 30 m and 600 m isobaths, from the border with South Africa to the border of Angola. The design of the survey was based on the hake swept-area surveys developed during the 1990s and 2000s by the R/V *Dr Fridtjof Nansen* and subsequently adapted by MFMR during annual surveys by the FV *Blue Sea* and other commercial vessels and more recently the R/V *Mirabilis*.

Hydrographic variables (depth, temperature, salinity and oxygen) were measured with a CTD at almost every bottom trawl station and along every degree of latitude an ecosystem transect was carried out with plankton, egg and larvae, micro-plastics and water for chemical analyses sampled at predefined bathymetric depths.

This report summarises the key data on the hake stocks, and several of the important bycatch species, for Leg 2.4, which covered the region from the Walvis Bay to the Cunene River. Results for other data collected, i.e. oceanographic, plankton, top predator, jellyfish, benthic invertebrate and hake biological data will be analysed in the context of research projects as part of the EAF-Nansen Science Plan.

During a post-survey meeting held in November 2019 the data from the surveys of southern and northern Namibia were combined and are presented in Chapters 4 and 5. A further section, Chapter 6, briefly investigates the transboundary distribution of the key demersal stocks between South Africa, Namibia and Angola.

This survey was conducted in April and May; all previous surveys since 1996 have been conducted in January-February. Hence the comparability of the results from this survey with previous surveys has to take into account this factor. The methodologies used by the 2018 survey were replicated as faithfully as possible during the 2019 survey, the main differences being, in addition to being conducted at different times of year, that the vessels were different. It should be noted however that the gear used on the R/V *Dr Fridtjof Nansen* and the R/V *Mirabilis* are the same, which strengthens comparability.

The estimate for Cape hake for the entire Namibian area is slightly higher than the recent estimates of the R/V *Mirabilis*, while for the deep-water hake the biomass appears somewhat lower. When compared to the longer time-series both estimates are broadly similar and suggest no overall trend in abundance.

Cape hake largely consisted of a single length-group from about 25 cm to 35 cm, showing that this species consists almost entirely of a non-fishable component. On the other hand, the biomass of deepwater hake was dominated by the fishable sized fish, although by number these represented just 12.6% of the total. For both species, very few fish greater than 75 cm were observed; these large fish are more accessible by long liners. Further, a cohort at around 17 cm (about one year old) was observed for both species.

During this survey, areas of high densities for *M. capensis* ($>20 \text{ t/NM}^2$) were found primarily inshore along 200 m isobath between 22°S and 25°S and between 17°S and 19°S. For *M. paradoxus* high-density stations ($>8 \text{ t/NM}^2$) were scattered along the entire coast.

Density distributions (t/NM^2) for hake: *M. capensis* (left) and *M. paradoxus* (right). Different scales are used to represent the two density distributions.

Recruits to the *M. capensis* stock are estimated from the numerical abundance of the cohort of fish with a modal length of about 22 cm (between 17 and 27 cm). These recruits are assumed to be about 1.5-2 years old. The recruitment of *M. capensis* at around 4.5 billion fish detected during the survey (the 2017-year class) was slightly higher than the long-term average. These fish are expected to fully recruit to the fishery by the second half of 2020, although some may currently be available to the bottom trawl gear. The strength of the *M. paradoxus* cohort cannot be estimated from the Namibian survey data, as the species does not appear to spawn in the Namibian waters.

Estimated number of recruits (1.5-2 years old) of *M. capensis* from the hake surveys off Namibia

CHAPTER 1. INTRODUCTION

The research activities under the EAF-Nansen Programme are guided by the EAF-Nansen Science Plan. The science plan is intended to ensure good scientific use of the wealth of data generated by the R/V *Dr Fridtjof Nansen* and other related data, addressing key research questions in support of tactical and strategic fisheries management.

The science plan covers 11 research themes, presented in Figure 1.

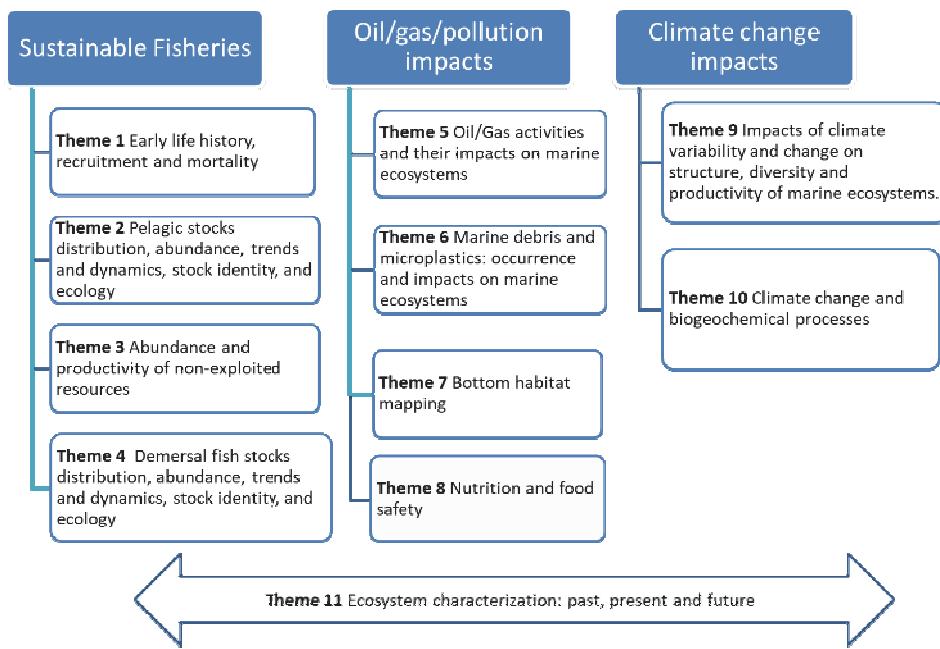

Figure 1. Research themes of the EAF-Nansen Science Plan

Leg 2.2 covered the continental shelf and upper slope of Namibia between the 30 m and 600 m isobaths, from the border with South Africa to Walvis Bay. The survey design followed that first developed by the Nansen Programme in the 1990s for hake biomass assessment (Sætersdal *et al.*, 1999) and used most recently by the Namibian research vessel *Mirabilis* (Paulus *et al.*, 2018).

1.1 Survey objectives

1.1.1 Hydrography

- To map the hydrographic and environmental conditions (temperature, salinity, dissolved oxygen, chlorophyll- α , nutrients and pH) and to obtain information on the dissolved oxygen concentrations, ocean acidification state and aragonite saturation state relevant for calcifying organisms.
- To identify oceanographic links of the Orange Bank with adjacent regions north and south.

- To collect data for the oceanographic model of the Orange Bank.
- Collect hydrographic data along standard MFMR Monthly Oceanographic Monitoring (MOM) lines as part of the Ministry's oceanographic time-series.

1.1.2 Zooplankton, ichthyoplankton and jellyfish

- To describe the abundance and biomass patterns of the mesozooplankton community, as well as its species composition.
- To provide information on the abundance patterns of the ichthyoplankton community (fish eggs and larvae), at the lowest possible taxonomic level.
- To collect samples of jellyfish for:
 - morphological identification and taxonomic studies,
 - genetic studies for the purposes of confirming identity, determining population structure and establishing regional and global connectivity,
 - histological examination of reproductive maturity to determine reproductive synchronicity and semelparity within populations and individuals, and
 - stable isotope analysis to determine trophic position and role.

1.1.3 Demersal resources

As the Namibian R/V *Mirabilis* was unable to conduct an adult hake biomass survey in 2019 and collect biological data on the hake stocks, the key objectives of Leg 2.2 and Leg 2.4 were therefore to assess the demersal resources of Namibia. Leg 2.2 covered the area from the border between Namibia and South Africa northwards to Walvis Bay. In this way legs 2.1, 2.2 and 2.4 provide a synoptic coverage of the demersal resources off Namibia and South Africa.

The survey was a standard swept-area bottom trawl survey replicating, as closely as possible, surveys conducted by the R/V *Mirabilis* in 2016, 2017 and 2018 and, previous to that, commercial vessels and the R/V *Dr Fridtjof Nansen*, and also the survey design used by the R/V *Dr Fridtjof Nansen* in South Africa in Leg 2.1. The key objective of Leg 2.2 was therefore to provide information on the biomass, distribution and stock structure of both species of hake, the species composition (catch composition) and also to provide data on the following:

- To collect standard biological data (length frequency, length-weight, sex and maturity) for both species of hake, also length and length-weight for monkfish and kingklip, as well as any other commercial species that may be abundant in the trawls.

- To collect environmental data using CTD casts at most trawl stations to enable subsequent studies investigating the distribution of the key demersal stocks and the environment.
- To monitor the acoustic data to ascertain if the target species (primarily hakes) occur above the trawl headline and hence are not available to the gear, and also for subsequent studies that are relevant to the distribution patterns of the above-mentioned species.
- To collect genetic samples to enable studies of the stock structure of hakes and key by-catch species: monkfish, kingklip, horse mackerel and Spanish mackerel.
- To collect samples of hakes, monkfish and kingklip to enable the study of parasite assemblages as biotags, and morphometric studies, supporting data already collected, and also allowing comparisons with South African samples.
- To collect gonad samples for fecundity studies of the spawning patterns of both species of hake.
- To opportunistically collect data on the distribution and species identification of juvenile hake for comparative studies of the distribution and size structure of catches of juvenile hake by the two vessels (R/V *Africana* and R/V *Dr Fridtjof Nansen*).
- To collect samples of juveniles of both species of hake as part of an investigation into identification using vertebrae counts.
- To collect benthic invertebrates from both trawls and sediment samples for species identification and species composition studies.

1.1.4 Pelagic resources

- To opportunistically collect samples of Cape horse mackerel (*T. capensis*) and *Scomber colias* for genetic analysis and morphometric studies.

1.1.5 Microplastics and neuston communities

- To map the occurrence and abundance of microplastics and the associated neustonic communities.

1.1.6 Marine mammals and seabirds

- To establish the distribution (including migratory) and relative abundance of whales, dolphins and seabirds off the coast of southern Namibia.

1.1.7 Mesopelagic fish, cephalopods and crustaceans

Mesopelagic fish, cephalopods and crustaceans have been sampled around the coast of Africa for a number of years by the Nansen Programme for the University of Western Cape in South

Africa. The samples collected are being used to determine the species' population structures, their trophic positions and ecological roles in the ecosystem, as well as establishing their regional and global connectivity. A recent loss of a large collection of frozen samples has jeopardized this programme and therefore extra effort was made during Leg 2.2 to collect a wide range of samples of these groups.

1.2 Survey area

The area surveyed in 2019 by the R/V *Dr Fridtjof Nansen* includes the continental shelf and upper slope of West Africa from South Africa to Morocco. Furthermore, a dedicated survey to the Discovery sea mounts in collaboration with SEAFO was carried out and mesopelagic transects were repeated off Walvis Bay and Morocco following the sampling strategy used in 2017. Figure 2 shows the overall survey programme for 2019 in southwest Africa.

Figure 2. The *Dr Fridtjof Nansen* survey plan for Leg 2

1.3 Participation

A total of 23 scientists and technicians from Namibia, South Africa and Norway participated in the survey. The full list of the participants and their affiliations is given in Table 1.

Table 1. List of participants, their role and affiliation during the survey off southern Namibia

Name	Role	Affiliation
Dave Boyer	Cruise leader	IMR
Sarah Paulus	Co-cruise leader, fish team	MFMR
Fredik Madsen	Acoustic engineer	IMR

1.4 Narrative

The vessel left Walvis Bay in the morning of 5 April 2019, 18 hours later than planned due to visa problems with one of the joining scientists, and steamed southwards towards the Orange Bank near the border with South Africa. Owing to strong south-westerly winds and a subsequent large swell, this region was only reached at sunrise on 7 April 2019. Intensive

CDT sampling was conducted along several transects across the Orange Bank during the next 24 hours. Trawling started at sunrise on 8 April 2019 and was the primary focus for the remainder of the survey.

The survey coverage off the southern part of the Namibian coast was completed on 23 April 2019 in the evening. The vessel came in to port at Walvis Bay at 08:00 local time on 24 April 2019 (Table 2).

1.5 Survey effort

The design of the survey was based on the hake swept-area surveys developed during the 1990s and 2000s for the R/V *Dr Fridtjof Nansen* (see Strømme *et al.*, 2015; also Anon, 2000; Anon, 2006; Axelsen & Johnsen, 2015) and subsequently adapted by MFMR during annual surveys by the *FV Blue Sea* and other commercial vessels and more recently the R/V *Mirabilis* (Paulus *et al.*, 2018).

A swept-area survey of this type usually takes 18-20 days to complete, from the first trawl off the Orange River until the final trawl on the 23°S transect off Walvis Bay. Only 16 days were available to complete this part of the survey as the original vessel schedule was to focus on the study of the ecology of juvenile hakes during Leg 2.2. In addition to the standard trawling, an array of plankton stations (known as super-stations) were also planned (Table 2).

Demersal trawling was carried out on predetermined positions within predetermined depth strata (as summarized in Table 3).

Hydrographic variables (depth, temperature, salinity and oxygen) were measured with a CTD at almost every bottom trawl station; several were dropped when time was particularly short and when there were two trawls within a couple of NM of each other – those in the 400 m and 500 m strata.

Along every degree of latitude (every 60 NM) an ecosystem transect (colloquially known as a “super-transect”) was carried out with CTD and zooplankton sampling stations at predefined bathymetric depths (Annex I). At each super-station, in addition to the CTD sampling, plankton, egg and larvae, micro-plastics and water for chemical analyses were all sampled. Some extra CTD data were collected at stations on the NatMIRC Monthly Oceanographic Monitoring lines, namely along the 28°, 26° and 23°S degree lines, and at several prescribed near-shore stations.

Acoustic echograms were continually recorded throughout the survey; the data was used to confirm, or otherwise, whether hake occurred more than about 5 m from the bottom, i.e. above the headrope, and were therefore not available to the trawl gear.

Table 2 summarises the overall survey effort, while Table 3 shows the area covered and effort per strata as used in the swept-area analyses. The cruise tracks with bottom-trawls, trawls, plankton and hydrographic stations can be found in Figure 3 to 5.

Table 2. Survey effort - number of CTD, multinet, Manta and bottom trawl stations

CHAPTER 2. METHODS

2.1 Underway hydrographic sampling

2.1.1 Meteorological data recording

Meteorological data were logged continuously from the AANDERAA Smartguard meteorological station and included wind direction and speed, air pressure, relative humidity, air temperature and solar radiation. All data were logged to the Nansis tracklog system averaged every 60 sec.

2.1.2 Thermosalinograph

A SBE 21 SeaCAT Thermosalinograph ran continuously during the survey, obtaining samples at 4 meters depth to measure salinity and temperature every 10 seconds. A Sea-Bird WETStar Fluorometer was also attached in-line to measure sub-surface fluorescence levels. There is a secondary temperature sensor close to the intake was used to report surface temperature.

Visual inspection of the salinity record showed periods with large ($\pm 0.1\%$) high frequency variations. These high frequency variations were probably caused by variable flow rates through the sensor. A few sudden jumps in salinity were also seen in the record, the largest was 0.17% . Comparison with salinity measured by the CTD showed that the thermosalinograph salinity was typically $0.10\text{--}0.20\%$ low, and variable. The surface salinity in the survey area is typically between 34.9% and 35.1% , thus the signal to noise ratio was considered too small for the salinity measurements from the thermosalinograph to be reliable.

High frequency variations were also seen in the temperature records, but the amplitude was only of a few hundredths of a degree and as the surface temperature varied between 12°C and 19°C , thus the signal to noise ratio was good. To remove the high frequency variations, the temperature data were filtered with a 31-point median filter (5 minutes long).

2.1.3 Current speed and direction measurements (ADCP)

The ship is equipped with two vessel-mounted Acoustic Doppler Current Profilers (VMADCP) from Teledyne RD Instruments mounted in the drop-keel and the frequency of the VMADCPs are 75 and 150 kHz. The data were collected by VmDas (Teledyne RDI) and processed on board using CODAS software from University of Hawaii (<http://currents.soest.hawaii.edu>). Data will be taken to IMR for horizontal distribution descriptions of ocean current velocity.

It was intended to run the 75 kHz ADCP in narrowband mode with 16 m vertical bins to a maximum 800 m depth and the 150 kHz ADCP in broadband mode with 4 m vertical bins to a maximum 250 m depth. The 75 kHz ADCP failed completely 3 days into the cruise, and we collected only about 36 hours of good data. The 150 kHz ADCP was run according to plan the first three days of the cruise, but for the remainder of the cruise it was run in narrowband

mode with 8 m vertical bins to a maximum 500 m depth. The heading data to convert the current recorded in the ship-referenced coordinates to the absolute zonal and meridional components were obtained from the vessel's differential GPS system, Seapath.

Most of the cruise was conducted in waters shallower than the maximum depth observable with the 150 kHz ADCP. Thus, the failure of the 75 kHz ADCP did not impact the ADCP data seriously. It was only at the deepest offshore end of the transects that we did not have coverage down to the bottom and the vertical resolution close to the surface was somewhat reduced.

2.1.4 Bottom mapping echo sounder

The EM 710 and EM 302 multibeam echo sounders are both high to very high-resolution seabed mapping systems. The EM 302 is hull-mounted whereas the EM 710 is mounted on the drop keel. The operational depths of the EM 710 are 3 to 2 000 m and of the EM 302 are 10 to 7 000 m. Across track coverage (swath width) is up to 5.5 times water depth and may be limited by the operator either in angle or in swath width without reducing the number of beams. The operating frequencies are between 70 to 100 kHz. There are 128 beams with dynamic focusing employed in the near field. The transmitting fan is divided into three sectors to maximize range capability and to suppress interference from multiples of strong bottom echoes. The sectors are transmitted sequentially within each ping and use distinct frequencies or waveforms. The along-track beam width is 1 degree. Ping rate is set according to depth. The receiving beam width is 2 degrees. Sound profiles were set manually in the system according to the area of operation. The EM 710 was not operational for most of the survey. Data from the EM 302 was logged to the on-board Olex plotting system and to raw data files.

During the survey, swath coverage and depth range settings were adjusted regularly to optimize the mapping. The measured sound speed profile was also input in the system when CTD measurements were carried out. Tide correction was not done.

The recorded data were viewed on Olex, the onboard navigation planning system.

2.2 Fixed station hydrographic sampling

A series of biological and oceanographic transects were sampled along every 3rd trawl transect on each degree of latitude, noting that the trawl transects in the southern part of the area were not east-west (they were perpendicular to the coast) and so the 28° transect was not along a trawl transect. These stations were referred to as “super-stations”. The standard Nansen sampling protocol is for super-stations to be at the 30 m, 100 m, and 500 m depths. In Namibia the continental shelf is particularly wide such that the 30 m and 100 m isobaths are often within a few NMs of each other, while the 500 m isobath is 50 NM or more away. Hence samples were collected at water depths of 30 m and 500 m, with an additional station approximately mid-way between these two stations, usually between the 100 m and 200 m isobaths. In addition, the distance between the 100 m and 200 m station was more than

50 NM on the 28° line and so an extra station was added at around the 250 m isobath. The 29° line was not sampled as much of this line fell within South African waters.

One test station was sampled at the beginning of the cruise. Four transects with three sampling stations on each, plus one transect with four stations, were completed on the cruise, thus 19 “super-stations” were sampled during the cruise. An overview of the number of samples collected is given in Annex IX

The samples collected on these transects are shown in Figure 6.

In addition to the transects stations where water samples were taken, additional CTD stations without water samples were sampled between the “super-stations”. Most of these were at trawl stations, but some were added to obtain reasonable horizontal resolution of the hydrographic parameters measured by the CTD. A summary of all the CTD stations sampled is shown in Annex II.

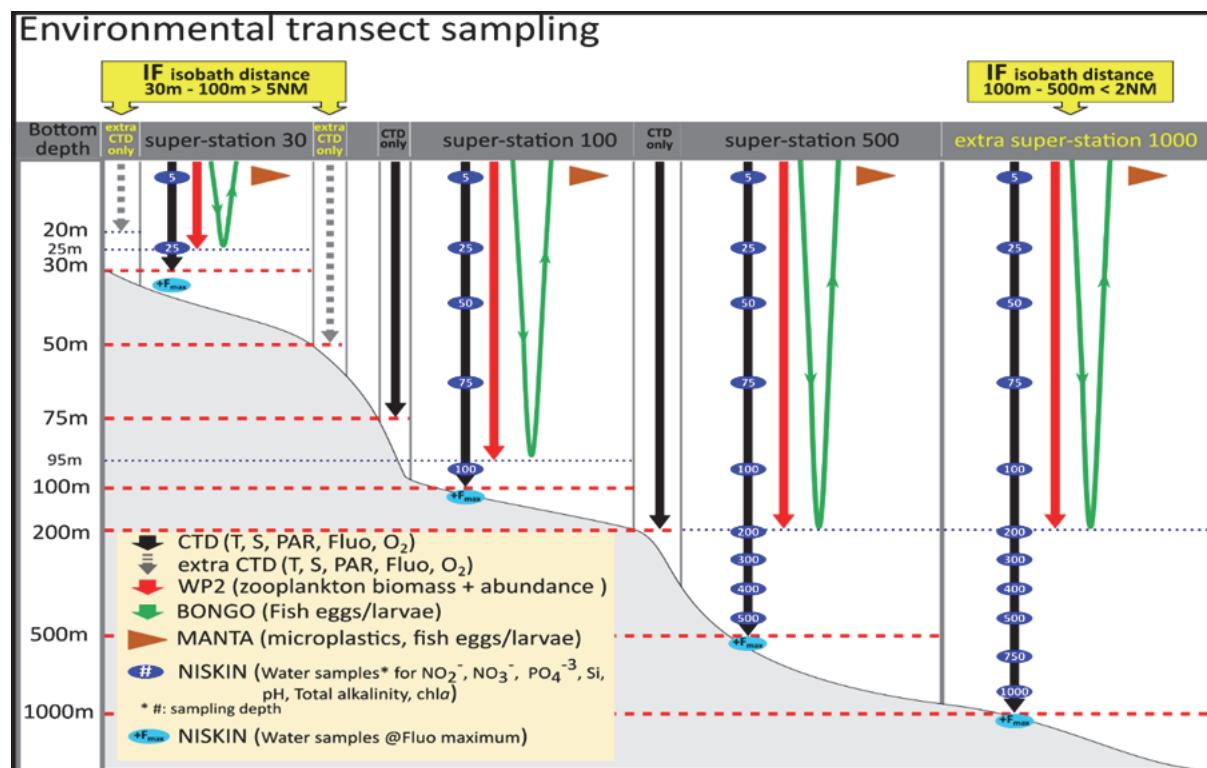

Figure 6. Sampling diagram showing the depth and the equipment used at the super stations transects, from the inshore (left side) towards the deep 500 m stations (right side).

At each super-station deployment, the 12-bottle rosette collected water at predefined depths during the up cast to obtain vertical profiles of pH, total alkalinity, nutrients, and chlorophyll- α . The CTD stopped at each predefined depth for at least 20 seconds to allow the bottles to rinse with the surrounding water as it reached equilibrium to best represent the water composition at that depth. In addition, further CTD stations were sampled at nearly all bottom trawl stations.

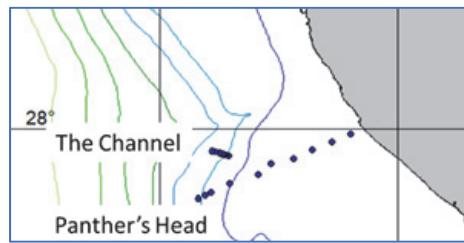

A Sea-Bird 911plus CTD containing two SBE 3plus temperature sensors, two SBE 4C conductivity sensors, a Digiquarts pressure sensor, a SBE 43 dissolved oxygen sensor, a

WET Labs ECO-AFL fluorometer and a Satlantic Photosynthetically Active Radiation LOG ICSW sensor were mounted to a 12-bottle rosette for every CTD deployment. All sensor logging and profiling was performed using Seabird's Seasave software.

Water was collected from low-gradient depths of 300 m and below to perform onboard validations of the conductivity sensor derived salinity values and the dissolved oxygen sensor values. The dissolved oxygen sensor measurements were validated using a Metrohm 916 Ti-Touch potentiometric titrator performing Winkler (Grasshoff *et al.*, 1983) and Karl Fischer titrations. The thermistor circuitry of Guildline Portasal Salinometer 8410A was not working (one of two thermistors were out of service), thus no water samples were analysed to validate the sensor salinity values.

Results of sensor calibrations of the hydrography sensors for water chemistry quality assurance are shown in Annex III.

Two high resolution hydrographic transects, will be used in a study aimed at identifying oceanographic links of Orange Bank with adjacent regions to the north and south and specifically to observe an anomaly noted in this area previously of a plume of cold waters that were being funnelled in against the coast from upwelling and the Benguela Current. Firstly, the Panther Head transect starting at 28°S and crossing the shelf in a west-south-westerly direction to the 650 m isobath at shelf slope was sampled. A second short high resolution transect was sampled at the shelf just north of the Panther Head transect, known as the Channel. These data will be analysed at a later date and be used as input to the oceanographic model of Orange Bank.

2.2.1 Ocean acidification parameters (pH and total alkalinity)

Water samples for pH and total alkalinity analyses were collected in the same 250 ml borosilicate glass bottle using silicone tubing. Since no preservative was used, it was necessary to keep the samples in the dark while waiting to stabilise at 25°C (with a water bath) for analysis. pH was determined using an Agilent Cary 8454 UV-Vis Diode Array spectrophotometer and a 2-mM m-cresol purple indicator dye solution. The indicator dye was measured every 24 hours to determine the correction factor appropriate for sample measurements (Clayton and Byrne, 1993; Chierici *et al.*, 1999). All pH spectrophotometric measurements were performed in duplicates on board. Total alkalinity was measured via an open-cell potentiometric titration using a 0.05M HCl solution with a sodium chloride background as the titrant (Dickson *et al.*, 2007). A Metrohm 888 Titrando equipped with an Aquatrode plus pH electrode with Pt1000 temperature sensor was used in combination with the Metrohm tiamo software to measure the change in pH and perform the total alkalinity titrations. Certified Reference Material of known total alkalinity from Scripps Institution of Oceanography was measured every 24 hours to determine the correction factor appropriate for sample measurements. All total alkalinity titrations were performed in triplicates on board.

2.2.2 Nutrient samples

Seawater samples for nutrient analyses (nitrite, nitrate, silicate and phosphate) were collected at standard depths (two samples at each depth) at each super-station in 20 ml polyethylene vials. Samples were preserved with 0.2 ml chloroform and kept refrigerated and dark (Hagebø and Rey, 1984) until being sent to the Institute of Marine Research for analysis. Analyses will be performed using a Skalar San++ Continuous Flow Analyser while following standard procedures (Grasshoff *et al.*, 1999). Storage and transport may introduce loss of accuracy of the results.

Once analyses are complete, phosphate and silicate concentrations combined with the on-board measurements of pH and total alkalinity will be used to calculate the area's inorganic carbon components along with the aragonite saturation state to update the ocean acidification status of the region.

2.2.3 Phytoplankton sampling

Water for chlorophyll- α samples were collected in 1 000 ml polyethylene bottles and subsequently divided into two 260 ml bottles for duplicate analyses. These water samples were collected from 200 m to the surface and filtered using a 0.7 μm glass-fibre filter (Munktell glass-fibre filters Grade: MGF, vacuum 200 mm Hg). The filters were stored in a freezer until they were transferred to centrifuge tubes with 10 ml of 90% acetone for 15 hours of extraction at 4°C. Samples were then centrifuged and transferred to cuvettes for measurement on a Turner Designs 10AU Fluorometer, according to Welshmeyer (1994) and Jeffrey and Humphrey (1975). First measured without acid for chlorophyll- α determination and then a second time with two drops of 5% HCl for phaeopigment determination. The 10AU is calibrated approximately every three months with standards created from a chlorophyll- α solid (from spinach).

Qualitative phytoplankton samples were not collected during the survey.

2.2.4 Plankton sampling

As described above, the environmental sampling grid consisted of 19 super-stations. Due to adverse weather conditions the deployment of all sampling devices was not possible at every station. The total number of stations sampled with each sampling device are summarized in Table 4.

Table 4. Overview of the plankton stations sampled

Sampling device	Number of stations sampled	Stations not sampled
Manta trawl (335 μm)	14	5
Multinet midi (405 μm)	18	1

Zooplankton samples were collected with vertical tows of a WP2 net (180 μm). The net was towed within 5-10 m of the bottom to the surface, or from 200 m depth to the surface at deep stations. Each sample was halved with a Motoda splitter. One half was size fractionated

through 2 000, 1 000 and 180 µm mesh sizes, and dried in the oven (60°C) in pre-weighed aluminium trays. The second half was preserved in 4% borax buffered formaldehyde solution.

Samples from the Manta trawl were sorted on board for microplastics and ichthyoplankton and sent to Bergen (IMR) and Cape Town (UWC), respectively for further analysis.

Ichthyoplankton was collected with double oblique tows of a Multinet midi net (405 µm). Samples were collected at most of the super-stations using double oblique tows within 5-10 m from the bottom to the surface, or a maximum depth of 200 m to the surface at deep stations. The double oblique hauls were performed differently on this leg opposed to the previous cruise due to different routines between the operators. The details can be found in the Multinet metafiles or scanned sampling sheets.

As stated in the sailing orders, once the Multinet was on board the sample was divided into two parts by use of a Motoda plankton splitter. Each part was treated as follows:

- a) One half of the sample was sieved on a 180 µm sieve and transferred to a 100 ml bottle (or bigger) and preserved immediately in 4% borax buffered formaldehyde (especially made for ichthyoplankton). These samples were labelled as “Not sorted” with a few exceptions.
- b) The other half was examined under the microscope and ichthyoplankton was sorted. Sorting was made at all of the Multinet stations. The sorted larvae were photographed and preserved in 96% ethanol in small labelled scintillation vials indicating clearly the part of the sample used (e.g. 50%), the preservative, station etc. When sorting was finished, the bulk sample was preserved in 4% borax buffered formaldehyde (especially made for ichthyoplankton) in bottles labelled as “Sorted”.

A few exceptions to this procedure were made since samples and fish larvae were relatively few. Samples containing fish larvae, juvenile fish or myctophids visual to the naked eye were picked from the sample before splitting and transferred to vials. These are therefore from the whole sample.

An overview of the sampling procedures followed in the plankton lab is given in Annex IV.

2.3 Top predator observations

Observations were carried out when weather permitted from the observation platform of the vessel, situated 21.5 m above sea level, during daylight hours between 07h30 to 17h30 (with breaks). Marine mammal observations were the main objective with seabird observations of secondary importance.

Primary observations were carried out in “passing mode”, meaning that the ship did not deviate from its track while sailing between oceanographic and fisheries sampling stations. The search effort changed from primary to secondary during such stations. Both marine mammal and seabird observations covered a forward angle of 180° from port to starboard.

The findings from this cruise will contribute to and improve the understanding of the recovery and distribution patterns of these threatened species in the region. These data sets will be submitted to the International Whaling Commission and Birdlife International, contributing to the decision making and conservation strategies with respect to these two groups of marine fauna.

2.3.1 Cetaceans

Scanning for animals to an approximate distance of 2.5 km from the vessel was performed by using either the naked eye or handheld Pentax (7 x 35, 9.3°) and Lynx reticular binoculars to locate and identify different species as well as to determine group sizes. In cases where a slightly spread out group of cetaceans was observed, the observation time, ship's position and the distance between the ship and first animal were recorded as if for the entire group. Sighting positions were obtained from a Garmin etrex 30 GPS. Species identification was carried out through the careful observation and photography (Canon EOS 80D camera with 100-400 mm telephoto lens) of specific features such as shape and height of the blow, body shape and size, colour patterns and animal behaviour. Two cetacean field and identification guides were consulted for more challenging identifications (Folkens, 2017 and Jefferson *et al.*, 2015).

All relevant sightings data were recorded on the standard International Whaling Commission's Cetacean Data Record Sighting form. Additional data such as ship's time (GMT+2), position of the ship, orientation (bearing) and distance of the animal(s) relative to the ship were also noted. Since adverse weather conditions negatively affects sight and visibility, parameters such as cloud cover, wind speed and direction, swell size, rainfall, water and air temperature and sea state were recorded hourly. Primary observations only ceased during oceanographic and fisheries sampling stations, dense fog, rain or wind speeds in excess of 20 knots in strength.

2.3.2 Seabirds

Seabird observations were conducted in similar fashion during daylight hours but at 10-minute increments, meaning that a GPS-position was recorded every 10 minutes and all seabirds observed during that period recorded. Observation area covered the forward angle of 180° from the port to starboard side and within a 300 m distance from the vessel. Observations were not carried out during oceanographic and fisheries sampling stations or during unfavourable weather conditions. Birds were recorded as in-flight or sitting on the water at the time of the sighting. Sightings were only recorded while the vessel was in transit between research stations. Observations started at least 30 mins after a trawl had been completed to give the vessel time to move away from the birds that gathered for the trawl pickings. Birds following the vessel between stations were not recorded. Searches for seabirds were performed either by naked eye or with handheld Pentax (7 x 35, 9.3°) and Lynx reticular binoculars. A Garmin etrex 30 GPS was used to obtain accurate ships positions. Seabirds were identified using their body shape and size, colour patterns and characteristics of flight. A Nikon D7000 camera with 80-200 m telephoto lens were used to further assist

with confirmation of species identification. A seabird field guide (Ryan, 2017) was also used to assist with species identification of unknown seabird species.

2.4 Bottom trawl fish sampling

2.4.1 Trawling strategy

A stratified semi-random design was used with depth and area as stratification factors. Trawl stations were located along a systematic survey track with approximately parallel transect lines perpendicular to the coastline, from 100 m to 600 m depth, equally spaced approximately 20 nautical miles apart. Along each transect trawls were placed at approximately 15 NM intervals, ensuring that each 100 m depth zone contained at least one trawl (as recommended at BENEFIT/BCLME survey design workshops, Anon 2000 & Anon 2006). These trawl positions were originally (in the early 1990s) randomly placed along the transects within each depth zone, but in recent surveys the same positions have been used in all years, thus these “random” positions have become fixed positions.

Trawls where the bottom depth was less than 400 m were carried out during daylight hours (07h00 to 19h00), as during the night hake and many other organisms lift off the bottom, a behaviour known as diurnal vertical migration (DVM), and are therefore not available to the trawl gear. This behaviour is believed to be less marked in waters deeper than 400 m (Kainge *et al.*, 2015). As most trawl positions were less than 400 m depth (66%) this presented special challenges in designing the course track, especially given the limited time available. It was not possible to conduct the survey on a transect-by-transect basis, but a certain amount skipping stations and then back-tracking at a later time was required.

Some trawl positions have in previous surveys proven to be on grounds where gear damage, and even loss, has occurred; these were usually, but not always, the deep trawls on the shelf-break or the shallow inshore stations on anoxic muddy bottoms to the south of Walvis Bay (Paulus *et al.*, 2018; Paulus *et al.*, 2016). Trawls were not attempted at these positions, but occasionally, when time allowed, alternative positions a few miles away, but within the same depth strata, were sampled.

Some trawls were hauled early as the door spread was declining and the net opening increasing, clear indications that the meshes of the codend were clogged with either jellyfish or sediments and benthic sea urchins and shell-fish. Trawls that had less than 10 minutes bottom contact were not used for density estimation (see below).

Following the Namibian protocol (Paulus *et al.*, 2018), all trawls that lasted longer than 10 minutes on the bottom were considered valid for biomass estimation regardless of the efficiency of the trawl. Trawls that were unstable with poor bottom contact or distorted gear configuration were included, as were trawls that dragged up large amounts of mud and boulders. Also, trawls where the catching efficiency was compromised by large amounts of jellyfish or small fish (myctophids or gobies) clogging the meshes were also used.

A detailed description of instruments and fishing gear is given Annex V. The complete records of fishing stations and catches are shown in Annex X.

2.4.2 Biological sampling

Biological sampling of fish was carried out from all bottom trawls.

All catches were sampled for composition by weight and numbers of each species caught. Species identification followed *FAO Species Identification Sheets for Fisheries Purposes*, and *Smith's Sea Fishes* (Smith *et al.*, 1988) in addition to several online databases especially the *Eschmeyer database* (Fricke *et al.*, 2019), WoRMS database (WoRMS Ed. Board, 2018) and *FishBase* (Froese and Pauly, 2018). Invertebrates were identified using the *Field Guide to Offshore Marine Invertebrates of South Africa* (Atkinson and Sink, 2018).

Biological data of both hake species was recorded from 20 specimens per species per trawl, selected randomly. Parameters recorded were length, weight, sex and gonad maturity stage, while otoliths were removed for later analysis (see Annex VII). Length (total length to the nearest cm) and weight (to the nearest 0.5 g) were recorded using the onboard electronic fish meters and scales. Length and weight were measured for up to 100 fish and were used to estimate the length-weight relationship and together with length frequency distributions, were applied in the biomass calculations.

Juvenile hakes (i.e. those measuring less than 15 cm) were frozen whole for subsequent vertebrate counts to differentiate between the two species. These data will also be used to compare with the vertebrae count of *M. polli* due to be collected during Leg 2.4 in northern Namibia and southern Angola.

Length frequencies and length-weight parameters were recorded for all other priority species, up to a maximum of 10 fish per degree latitude. The species sampled were:

- *Lophius vomerinus*
- *Genypterus capensis*
- *Helicolenus dactylopterus*
- *Chelidonichthys capensis*

Relatively few of the following priority species were caught and although sampled, the results are not presented in this report:

- *Beryx splendens*
- *Austroglossus microlepis*

In addition, samples for genetic analysis at IMR, including parasite biotags, were collected for NatMIRC, and gonad samples were taken for Lungelwa Nomxego at DAFF in Cape Town (Table 5).

Table 5. Main target species sampled and preserved for future genetic and gonadal studies

Species	Specific sampling
<i>M. paradoxus</i> and <i>M. capensis</i>	Genetics 5 small fish (<40 cm TL) and 5 large fish (>40 cm TL) per degree The distal 5 mm of the left pectoral fin was removed (fin-clipped) and preserved in 95% ethanol The remainder of the fish was frozen whole Gonads: The ovaries of 30 females per degree (with a maximum of 10 fish per trawl) were removed from fish >45 cm and stored in 4% formalin. Note that trawls often contained insufficient large fish for both genetic and gonad samples; the genetic sampling was prioritised
<i>L. vomerinus</i> and <i>G. capensis</i>	Genetics 10 fish per degree The distal 5 mm of the left pectoral fin was removed (fin-clipped) and preserved in 97% ethanol The remainder of the fish was frozen
<i>Trachurus capensis</i> and <i>Scomber colias</i> (<i>S. japonicus</i>)	Genetics 10 fish per degree The distal 5 mm of the left pectoral fin was removed (fin-clipped) and preserved in 97% ethanol The remainder of the fish was frozen

Mesopelagic fishes, cephalopods and crustaceans caught as part of a trawl haul were identified to the lowest taxonomic level where possible. Ten individuals (if available) of each taxa present were rinsed with fresh water, dried using paper towel and stored in zip-lock bags at -20°C.

A flow diagram of the sampling procedures used in the fish lab is shown in Annex VIII.

A summary of the samples collected, including the purpose of collection and the receiving laboratories is shown in Annex IX.

2.4.3 Demersal invertebrate sampling

Two stainless steel cylinders (approx. 2 litres in volume) were mounted on the footrope of the trawl to collect bottom sediment samples at every trawl station. A few stations were not sampled as the cylinders created an injury risk for the deck-crew in very rough weather. The samples were collected from the cylinder when the trawl was on deck and all macro-invertebrates removed and fixed in 97% ethanol for later analysis at UNAM. All invertebrates in the trawl, or the sampled part of the catch if large, were also identified, if possible, and

counted. All unidentified specimens were photographed and fixed in 97% ethanol, also for later analysis at UNAM.

2.4.4 Swept-area biomass calculations

Stock biomasses were estimated by the swept-area method with catch per haul as the index of abundance (see Strømme, 1992).

The general formula to estimate biomass B, using this method is:

$$B = \frac{A}{a} \cdot \frac{\bar{X}}{q}$$

where A is the total area surveyed, a is the swept-area of the net per haul, \bar{X} is the average catch per haul (the index of abundance) and q (trawl catchability) is the proportion of fish in the path of the net that are actually caught. The density of the resource is estimated as biomass per unit area. In a stratified survey of k non-overlapping strata, if the mean catch per haul in stratum i and its variance are denoted by \bar{X}_i and s_i^2 respectively, then an unbiased estimate of the population mean \bar{X} is the stratified mean \bar{X}_{st} , which is given by:

$$\bar{X}_{st} = \frac{1}{N} \sum_{i=1}^k N_i \bar{X}_i = \sum_{i=1}^k W_i \bar{X}_i$$

where $W_i = \frac{N_i}{N} = \frac{A_i}{A}$ is the statistical weighting factor expressed as relative size of the i^{th} stratum with A_i the area of the i^{th} stratum and A is the total area surveyed. The variance of the stratified mean is given by

$$\text{var}(\bar{X}_{st}) = \sum_{i=1}^k W_i^2 \text{var} \bar{X}_i = \sum_{i=1}^k W_i^2 \frac{s_i^2}{n_i}$$

where n_i is number of hauls in the i^{th} stratum and n is the total number of hauls in the survey.

For conversion of catch rates (kg/h) to fish densities (t/NM²), the effective fishing area was considered as the product of the wing spread and the haul length, or distance over the bottom, as measured by means of the SCANMAR® equipment based on GPS readings. The area swept for each haul was thus 18.5 m (traditionally applied wing spread for the “Nansen” bottom trawl) times the distance trawled, raised to NM²/hour. In most hauls the trawling time (with the gear at the bottom) was around 30 min, which with a towing speed of 3.0 knots and an average horizontal trawl opening of 18.5 m efficient net width gives an area swept by the trawl net of typically around 0.015 NM². Diagrams of the bottom trawl used are shown in Annex V.

The catchability coefficient (q), i.e. the fraction of the fish encountered by the 18.5 m horizontal opening of the trawl that was actually caught, was assumed equal to 1, which leads to an estimation of the biomass which allows for comparison with previous surveys. Catchability may vary depending on the type of gear used and the type of species (e.g. gears with bobbins are less efficient for species such as flat fishes and octopus, as compared to gears without bobbins and with footrope touching the bottom). For this reason, biomass estimates are to be considered indices of abundance and not absolute values.

Mean fish densities by species and strata were calculated by the traditional method used in previous surveys (Excel spreadsheets). The newly developed StoX software was not used as the area maps for Namibia in the format required by StoX were not available. The biomass estimates per strata were also calculated using the Namibian spreadsheets (which had originally been developed by the Nansen Programme); the same answers were obtained using both methods.

Table 6 shows the areas used in the swept-area method to estimate biomass for the different regions. Estimated total biomass by species/group was obtained by summing estimates for each depth stratum.

Table 6. Depth strata in NM² by latitude for southern Namibia (the area covered during Leg 2.2). Based on echosoundings from Nansen surveys 1996-2003. Depths from surface to bottom (Strømme *et al.*, 2010)

	100-200	200-300	300-400	400-500	500-600	Total all strata
23°-24°	2 006	1 074	670	238	153	4 141
24°-25°	1 343	822	753	238	149	3 305
25°-26°	1 580	1 102	529	227	166	3 604
26°-27°	894	986	1 408	744	140	4 172
27°-28°	1 269	527	858	480	205	3 339
28°-29°	4 207	391	153	123	164	5 038
29°-30°	1 042	533	327	276	162	2 340
Total area 23°-30°	12 341	5 435	4 698	2 326	1 139	25 939
All Namibia	20 091	9 842	8 848	3 543	2 200	44 524

NB. The total area for all of Namibia as reported by Strømme *et al.*, 2010, is 0.7% greater than that used in the Namibian hake surveys conducted by the R/V *Mirabilis*. It is not clear why this difference exists.

2.4.5 Calculation of swept-area fish density estimates and conversion to biomass

For target species, where length-based estimates are more useful, a slightly different procedure was followed. The total biomass in the two methods are the same.

Swept-area fish density estimation by species and length are used to calculate density and biomass of target species from the bottom trawl catches (Jacobsen, 1997).

The calculations are carried out as follows.

$$p_{s,l} = \frac{f_{s,l}}{a_{s,l}}$$

Where:

$p_{s,l}$ = number of fish of length l per NM² observed on trawl station s

$f_{s,l}$ = estimated frequency of length l

$a_{s,l}$ = swept-area:

$$a_{s,l} = \frac{d_s * EW_l}{1852}$$

Where:

d_s = towed distance

EW_l = length dependent effective fishing width.

The length dependent effective fishing width incorporates the q catchability coefficient described in the previous section and is kept constant at 18.5 m during the R/V *Dr Fridtjof Nansen* surveys. The parameter corresponds with the width of the Gisund super bottom trawl used during swept-area surveys.

Stratified abundance indices for each length group and strata can then be calculated from:

$$L_{p,l} = \frac{A_p}{S_p} * \sum P_{s,l}$$

Where:

$L_{p,l}$ is the index (total number of fish estimated) for stratum p, length group l

A_p is the area (NM²) of stratum p

S_p is the number of stations in stratum p

The length frequencies used for estimating numbers at length, and illustrated in this report, were calculated from the length frequencies of individual trawls raised to the density of fish at that station (i.e. raised by the sample size compared to the total catch and the length of the trawl).

The abundance per length group is then converted to density by applying a calculated weight at length ratio using regression analyses on the measured (l) and weighted (w) fish in the trawl catches.

$$w = a * l^b$$

2.5 Jellyfish collection

Jellyfish were sampled from the trawl hauls. When the total catch was considered too big, the catch (fish, jellyfish, etc.) was sub-sampled. Thereafter, all jellyfish specimens caught, or representative random samples thereof, were identified to the lowest possible taxon.

Chrysaora fulgida and *C. hysocella* specimens were measured and weighed. Two small sections of the oral arm tissue were removed and preserved in both 96% ethanol (EtOH) and FDL Storage Buffer and stored at -20°C. This will be used to compare effectiveness of the storage methods of DNA material as well as for genetic analysis. After 24 hours, the 96% EtOH was drained from each sample and replaced with fresh 96% EtOH and the sample was stored at -20°C until analysis. The gonads were removed from each individual and stored in 7% seawater formalin. A few whole specimens were also stored in 8% sea water formalin.

Pelagia noctiluca specimens were measured and preserved whole in 96% EtOH and stored at -20°C. After 24 hours, the 96% EtOH was drained from each sample and replaced with fresh 96% EtOH and the sample was stored at -20°C until analysis. This species is relatively small and preserves well in EtOH which allows both morphometrics and genetic analysis back on land.

Aequoria forskalea, *Chiropodus gorilla* and *Discomedusa lobata* specimens were measured and preserved whole in 10% seawater formalin.

2.6 Acoustic sampling

2.6.1 Sonar data

No sonars were used during the survey.

2.6.2 Echo sounder

Acoustic data were recorded using a Simrad EK80 Scientific Split Beam Echo Sounder equipped with keel-mounted transducers at nominal operating frequencies of 18, 38, 70, 120, 200 and 333 kHz. A calibration conducted in Walvis Bay on 28 and 29 March 2019 gave spurious results and hence the echosounder gains were retained from the previous calibration, conducted in Bergen on the 23 January 2017. Annex V gives the details of the acoustic settings used during the survey.

2.6.3 Allocation of acoustic energy to species group

Acoustic data were logged and post-processed on board using the latest acoustic data post-processing software, the Large-Scale Survey System (LSSS) Version 2.5.0.

Scatters were displayed at 38 kHz. The mean 5 NM area backscattering coefficient s_A (m^2/NM^2) was allocated to a predefined set of species groups on the basis of established echogram features and stored as mean values per 1 NM. The species groups and respective species are listed in Table 7.

The acoustic data were only used as supporting information to the trawl data; no acoustic biomass estimation was attempted. The echograms were scrutinised during the survey primarily to indicate if large amounts of hake occurred above the trawl headrope and therefore were potentially not available to the trawl sampling gear. Such trawls have been flagged in the data (see Annex X), but all valid trawls were used in calculating the biomasses.

The acoustic data are available for subsequent analysis although it must be noted that the scrutinisation carried out on board was done without any targeted midwater trawls to identify the targets; the identifications recorded in the LSSS system were the best assessments of the scrutinisers, based on many years of accumulated experience of similar surveys in Namibia, and guided by the catches of the bottom trawls in that area, but these identifications must be used with caution.

Table 7. Allocation of acoustic densities to species groups

Group	TAXON	Key species
Hake	Merluccidae	<i>Merluccius capensis</i> <i>M. paradoxus</i>
Horse mackerel	Carangidae	<i>Trachurus capensis</i>
Mackerel	Scombridae	<i>Scomber colias</i> <i>S. japonicus</i>
Pelagic 1	Clupeiformes	<i>Etrumeus whiteheadii</i>
Pelagic 2	Gempylidae	<i>Thyrsites atun</i> <i>Lepidopus caudatus</i>
Other demersal and semi-pelagic species		<i>Chelidonichthys capensis</i> <i>C. queketti</i> <i>Brama brama</i> <i>Helicolenus dactylopterus</i> <i>Zeus capensis</i> <i>Emmelichthys nitidus nitidus</i> and other species
Mesopelagic species (most abundant species recorded)	Gobies Myctophidae	<i>Sufflogobius bibarbatus</i> <i>Symbolophorus boops</i> <i>Lampanyctodes hectoris</i> <i>Phosichthys argenteus</i> <i>Diaphus hudsonii</i>
Plankton	Various	
Jellyfish	Various	<i>Aequorea forskalae</i> <i>Pelagia noctiluca</i>

CHAPTER 3. RESULTS

3.1 Oceanography

3.1.1 Wind speed and directions

Wind data presented in Figure 7 and Figure 8 show that the wind was predominantly from the south and generally strong, with two extended periods of winds averaging more than 20 knots.

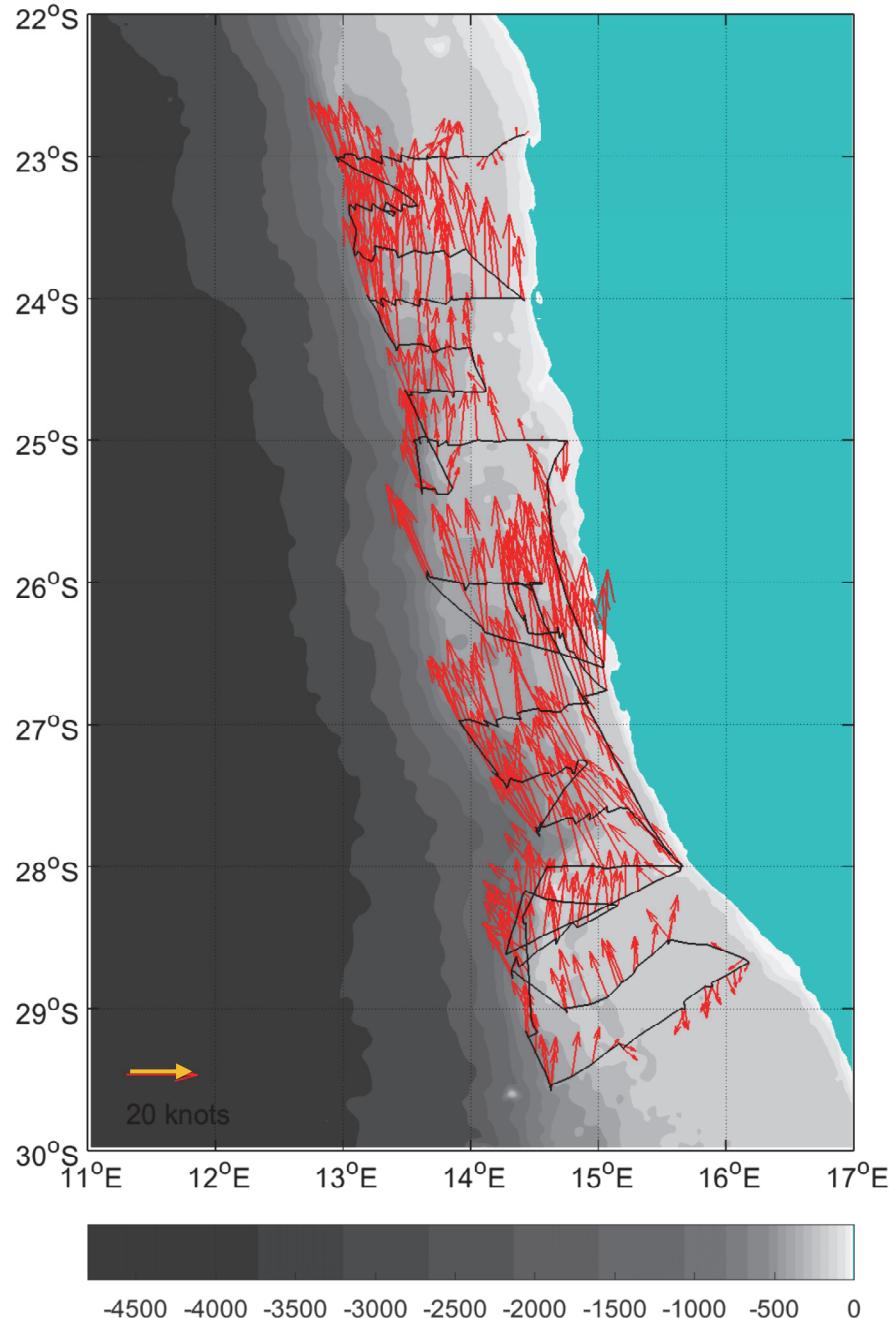

Figure 7. Wind vectors (10 minute averages, an arrow every 3 hours)

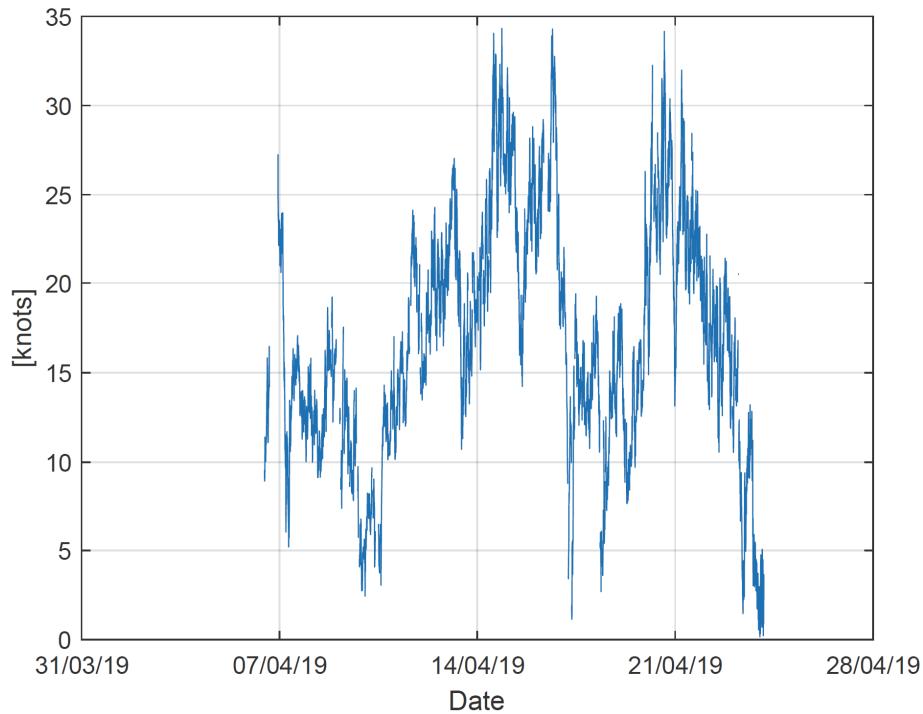

Figure 8. Wind speed (10 minute averages) as function of time

3.1.2 Horizontal distribution of oceanographic parameters

Six hydrographic super-transects were occupied where water was collected for chemical analyses in addition to 129 normal CTD sensor measurements. Summarised data of the oceanographic parameters are presented in Figures 9 to 15.

Lowest sea surface temperatures were recorded at the coast, increasing offshore. The highest surface temperatures were observed south of 26° S, with temperatures above 18 °C in the south-western corner of the survey area. In contrast, the highest bottom temperatures were inshore and to the north of the area.

A large area of hypoxic waters occurred north of 26°S from inshore to beyond the 300 m isobath. This water was essentially anoxic at depth.

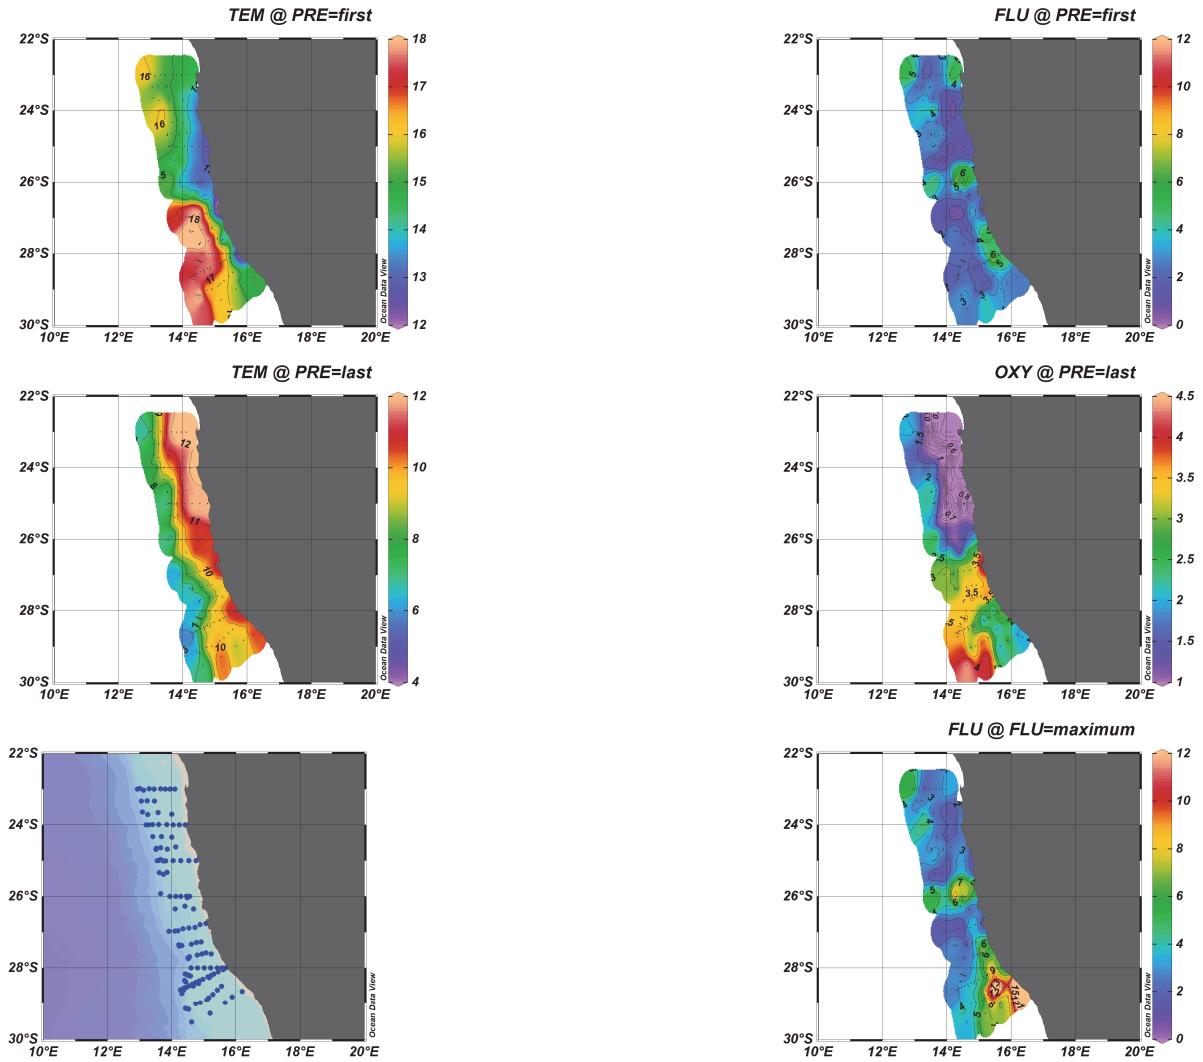

Figure 9. Horizontal distribution of oceanographic parameters. Temperature and fluorescence at shallowest CTD observation depth (~5 m, top panels). Temperature and dissolved oxygen station at bottom depths (mid panels). Fluorescence maximum in the water column (bottom right). Note different temperature scales for surface and bottom temperatures. Position of CTD stations shown at bottom left

3.1.3 Vertical distribution of oceanographic parameters

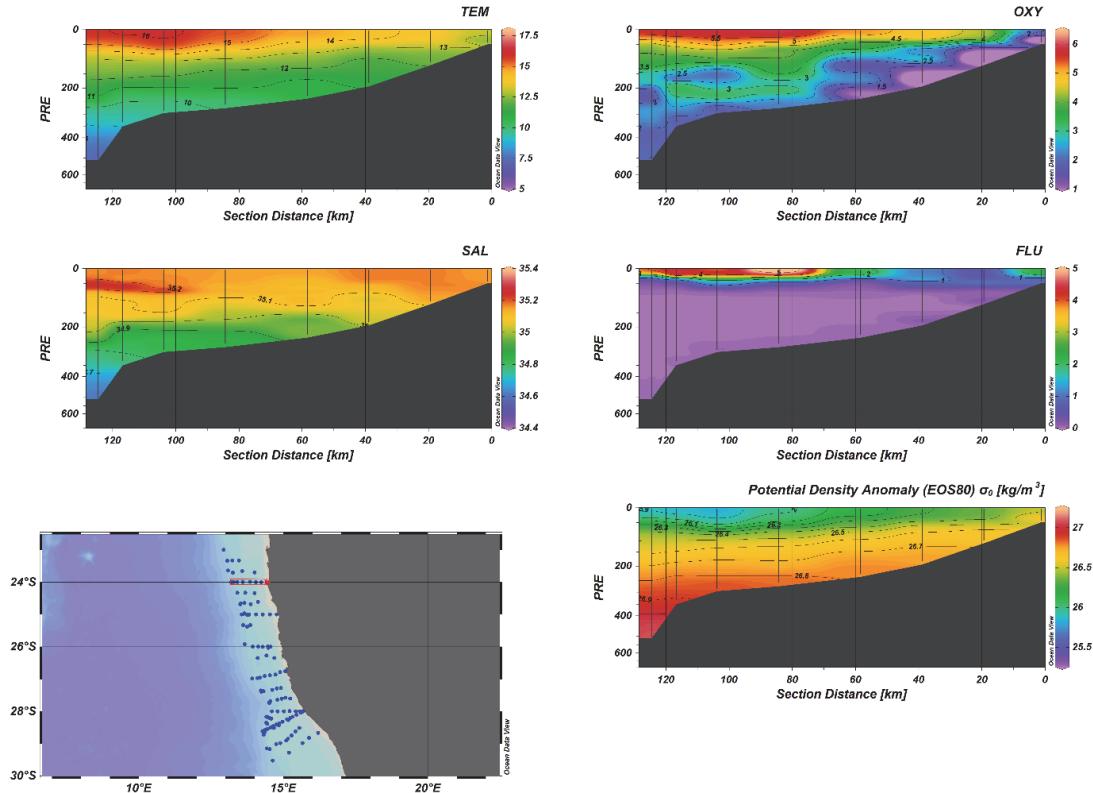

Figure 14. Temperature, salinity, dissolved oxygen, fluorescence and potential density of cross shelf sections at 24°S from the coast in westerly direction

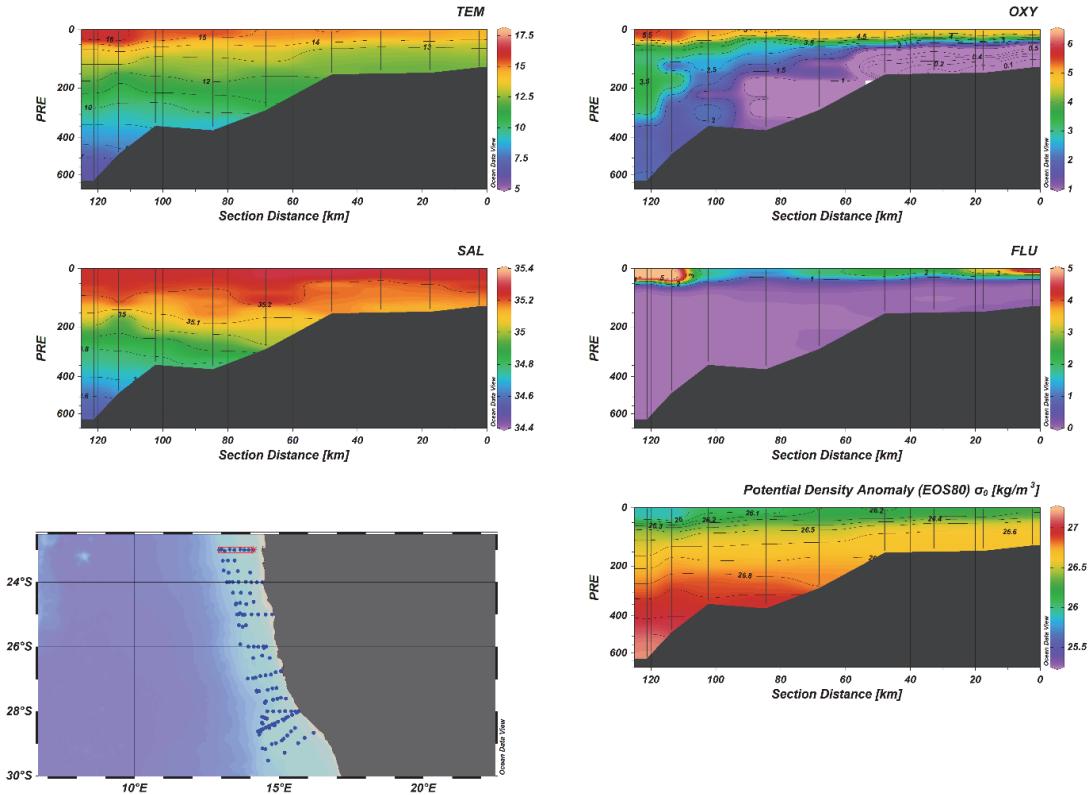

Figure 15. Temperature, salinity, dissolved oxygen, fluorescence and potential density of cross shelf sections at 23°S in westerly direction, starting from the 125 m isobaths

3.2 Plankton and microplastic sampling

3.2.1 Zooplankton

A total of 58 aluminium trays for zooplankton dry weight estimation were produced during the survey and transferred to IMR for zooplankton biomass estimation. A total of 19 WP2 samples (4% borax buffered formaldehyde) was transferred to NatMIRC in Namibia for future zooplankton taxonomic identification.

3.2.2 Ichthyoplankton

A total of 18 unsorted bulk Multinet samples preserved in ethanol were transferred to NatMIRC for future ichthyoplankton sorting and identification.

A total of 19 jars with bulk plankton and 10 scintillations vials with fish larvae and eggs (all preserved in 4% formaldehyde solution) were transferred to NatMIRC for rechecking ichthyoplankton presence and taxonomic identification of the ichthyoplankton, respectively.

Fish eggs and fish larvae abundances collected with a Manta trawl and Multinet sampler during the survey period, are given in Table 8. Some examples of the eggs and larvae, and juvenile fish and myctophids captured, are shown in Figures 16 to 18.

Table 8. Numbers of ichthyoplankton collected in the Manta trawl and Multinet sampler

Station	Manta		Multinet

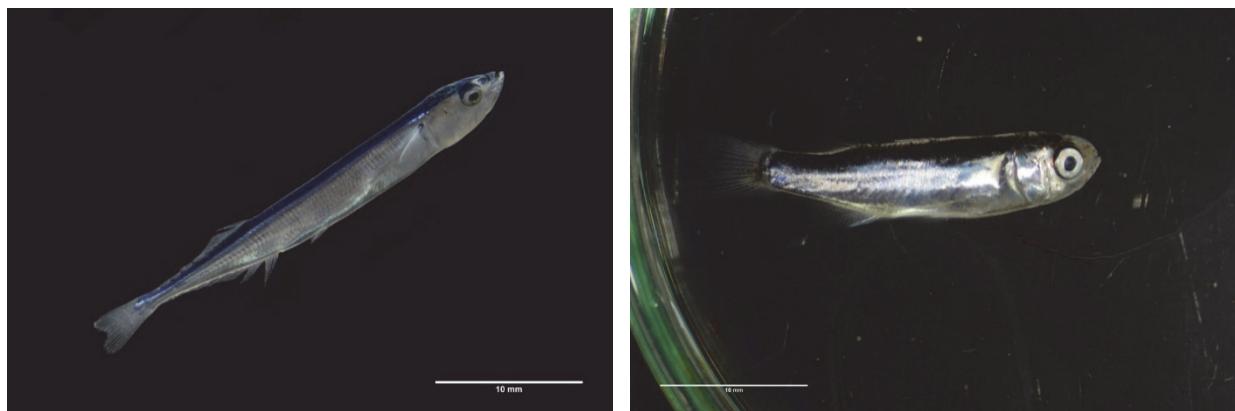

Figure 17. Examples of fish larvae collected in the Manta net

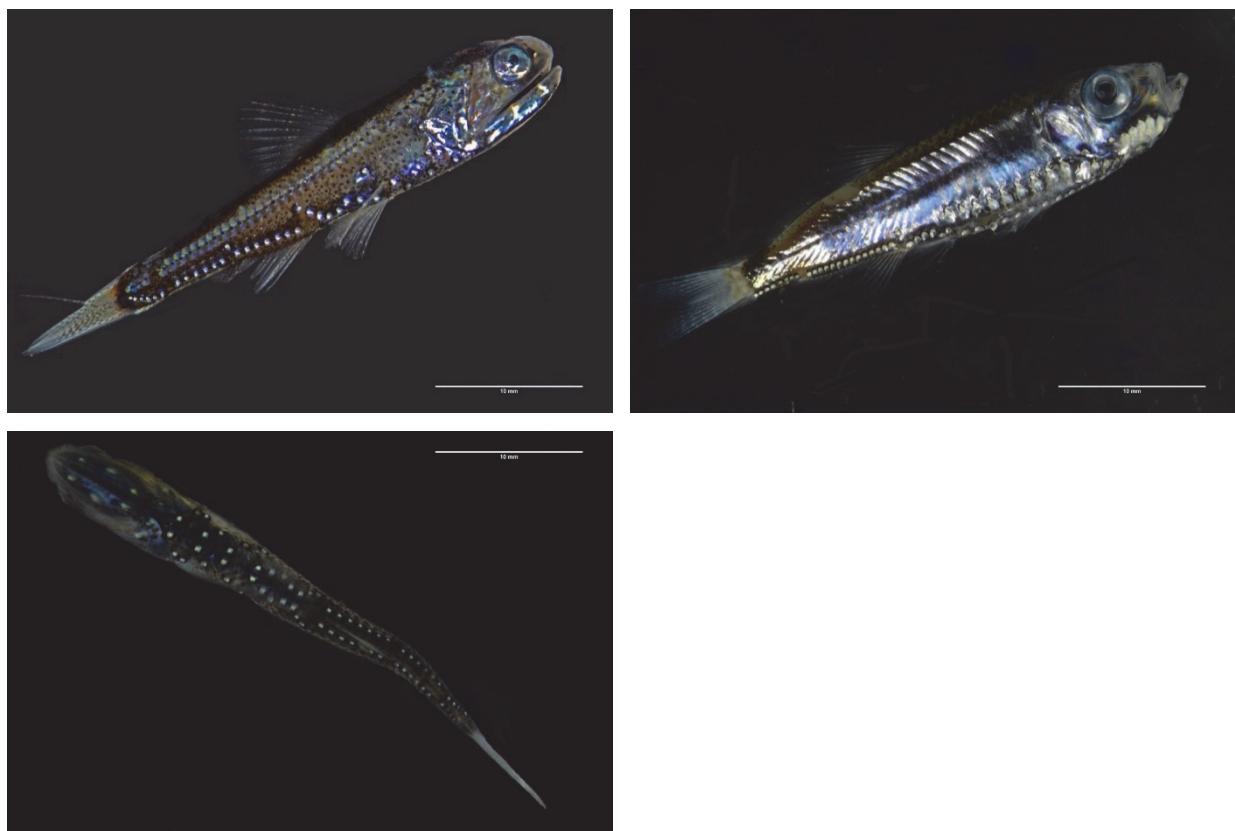

Figure 18. Examples of myctophids collected in the Manta net

3.2.3 Microplastics and Debris

From the Manta trawl hauls a total of 15 aluminium trays with microplastics were transferred to IMR for further processing. A total of 10 scintillation vials, and one 100 ml bottle with sorted larvae and eggs preserved in 96% ethanol and one 100 ml bottle with sorted larvae and eggs preserved in 4% formaldehyde were transferred to IMR for taxonomic identification and genetic analysis. A total of 15 bulk Manta trawl samples (14 x 100 ml and 1 x 500 ml bottles) preserved in 96% ethanol were transferred to the University of Western Cape, South Africa, for future analysis.

Little plastic debris was collected during the survey. The foreign objects that were found were photographed under the microscope and packed on aluminium trays. Most of these objects were paint from the ship, a few were identified as plastic, mostly micro-fibres also from the ship. Some examples are shown in Figure 19.

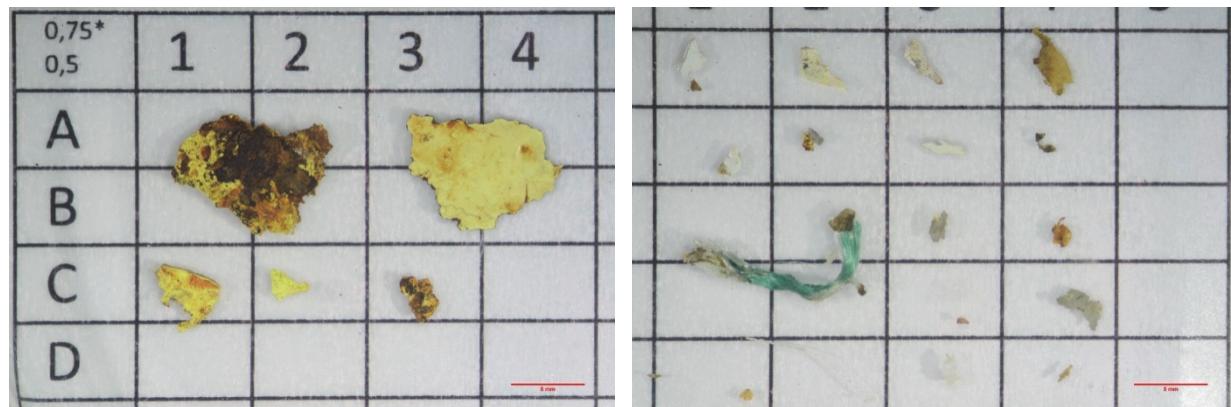

Figure 19. Examples of microplastics found in the Manta net

3.3 Top predator observations

3.3.1 Cetaceans

The area of observation, both for primary (when the vessel was steaming) and secondary (when the vessel was fishing or on stationary) observations for both cetaceans and birds is displayed in Figure 20. Fifty-three hours and 25 minutes were spent on primary observations, averaging 2.80 hours per day over the duration of the cruise. Unfavourable weather conditions such as strong winds, mist and rain were all factors that contributed negatively to the low hours on watch (Annex XII). A total of 16 sightings of 273 individual whales and dolphins belonging to 8 different species were made (Figure 21). Figure 22 illustrates the position of the sightings. Dusky dolphins *Lagenorhynchus obscurus*, were seen on six occasions, sometimes in large groups. The rarely seen Southern Right Whale dolphin *Lissodelphis peronii*, was briefly seen on two occasions and a Cuvier's Beaked Whale *Ziphius cavirostris*, was seen on one occasion. Minke Whale *Balaenoptera acutorostrata*, Sperm Whale *Physeter macrocephalus*, and Sei Whale *Balaenoptera borealis* were also identified. Three species that were seen and could not be positively identified were recorded as "Like" Minke Whale *Balaenoptera acutorostrata*, Fin Whale *Balaenoptera physalus* and Bottlenose dolphin *Tursiops truncates*.

The low number of sightings can largely be attributed to the majority of the region's whales being in the southern oceans this time of the year during the whales' annual summer feeding migration.

Figure 20. Top predator observations area during the survey

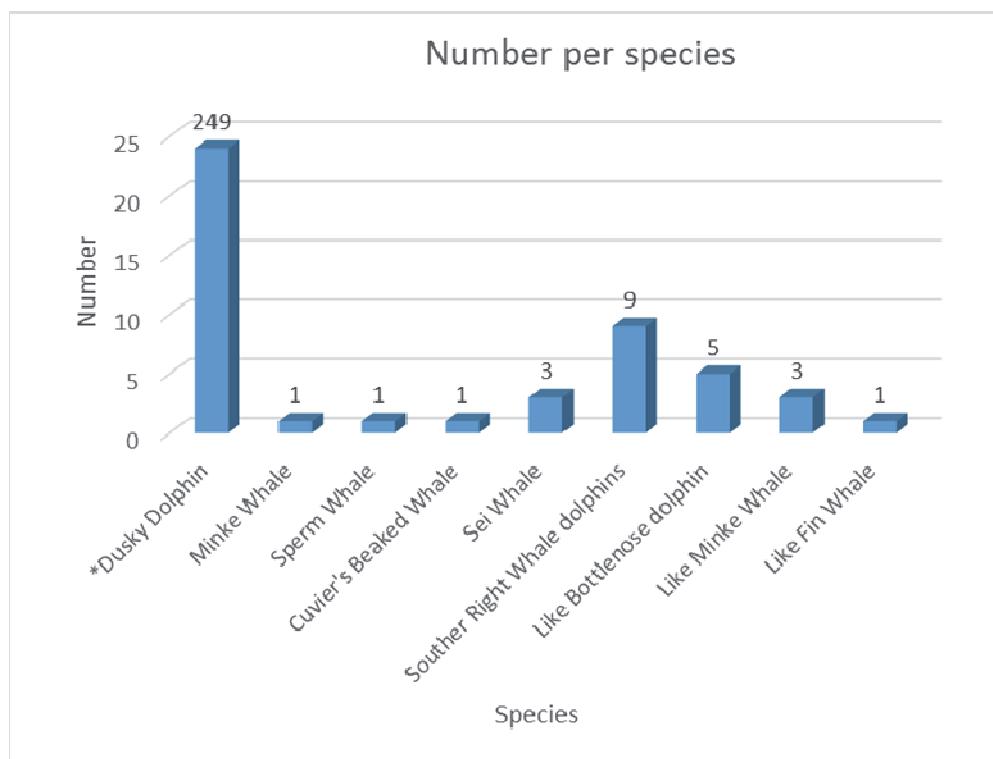

Figure 21. Number of cetaceans observed per species

(*The count for Dusky dolphin has been deliberately reduced 249 to 24 in order to improve the appearance of the graph)

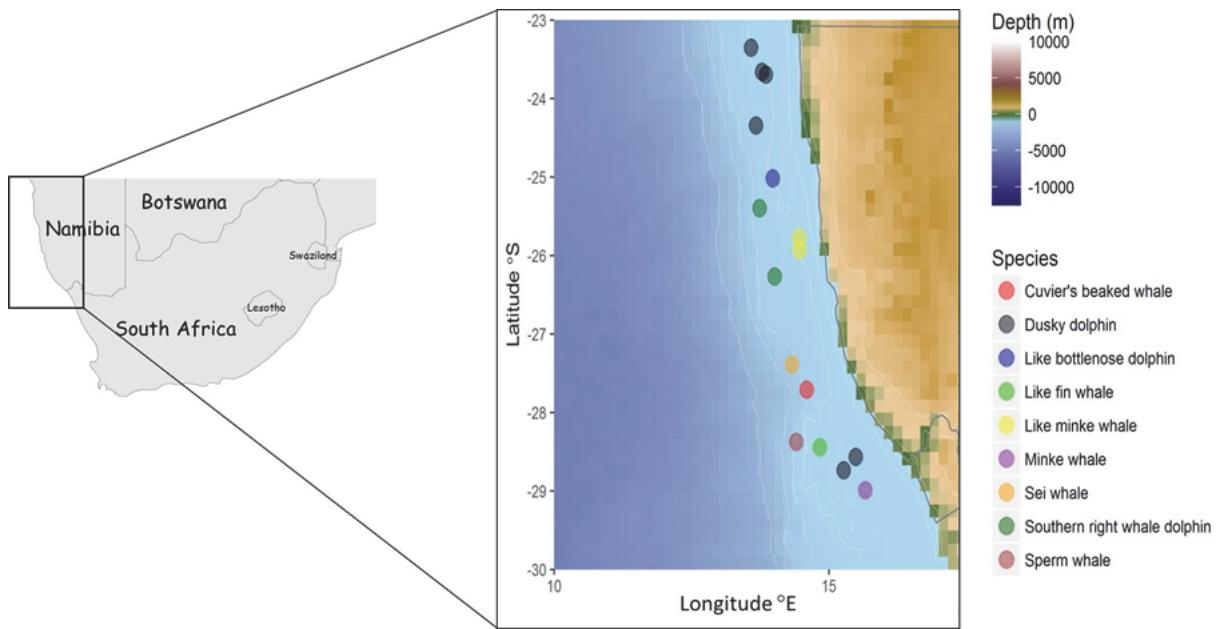

Figure 22. Distribution of marine mammals sighted along the southern Namibian coast

3.3.2 Seabirds

A total of 330 birds from 19 different seabird species were identified and counted in 99 (10 min) transects during the 16 hours 43 minutes of primary observations for seabirds carried out during this cruise (Table 9). White-chinned Petrels (*Procellaria aequinoctialis*) were the most abundant species encountered with 377 individuals recorded. Although not rare, several species that are not often seen in southern African waters were recorded; Salvin's Albatross (*Thalassarche salvini*) and Spectacled Petrel (*Procellaria conspicillata*) were seen each on two occasions while not on effort. Spectacled Petrel was seen on 11 April 2019 at 28°23'S and 014°26'E and 28°00'S and 014°36'E. On 12 April 2019 at 27°39'S and 14°48'E an Antarctic Tern (*Sterna vittata*) was seen around the vessel. On 17 April 2019 at 25°04'E and 14°01'E and on 18 April 2019 at 25°20'S and 13°37'E a Salvin's Albatross was seen.

Table 9. Seabird species and numbers observed during primary observations

Species	No.
African Penguin (<i>Spheniscus demersus</i>)	2
Artic Tern (<i>Sterna paradisaea</i>)	26
Common Tern (<i>Sterna hirundo</i>)	23
Swift Tern (<i>Thalasseus bergii</i>)	1
Unidentified terns	40

Black-browed Albatross (<i>Thalassarche melanophrys</i>)	125
Shy Albatross (<i>Thalassarche cauta</i>)	87
Unidentified albatrosses	6
Total	1 105

3.4 Fish sampling

3.4.1 Swept-area abundance and distribution

Figure 23 shows densities of Cape hake along the southern coast of Namibia. The mean density for all valid trawl stations was 12.75 tonnes/NM².

Cape hake, *Merluccius capensis*, occurred almost entirely in depths less than 400 m with the highest densities between the 200 m and 300 m isobaths. The densest concentrations were found between Lüderitz and Walvis Bay.

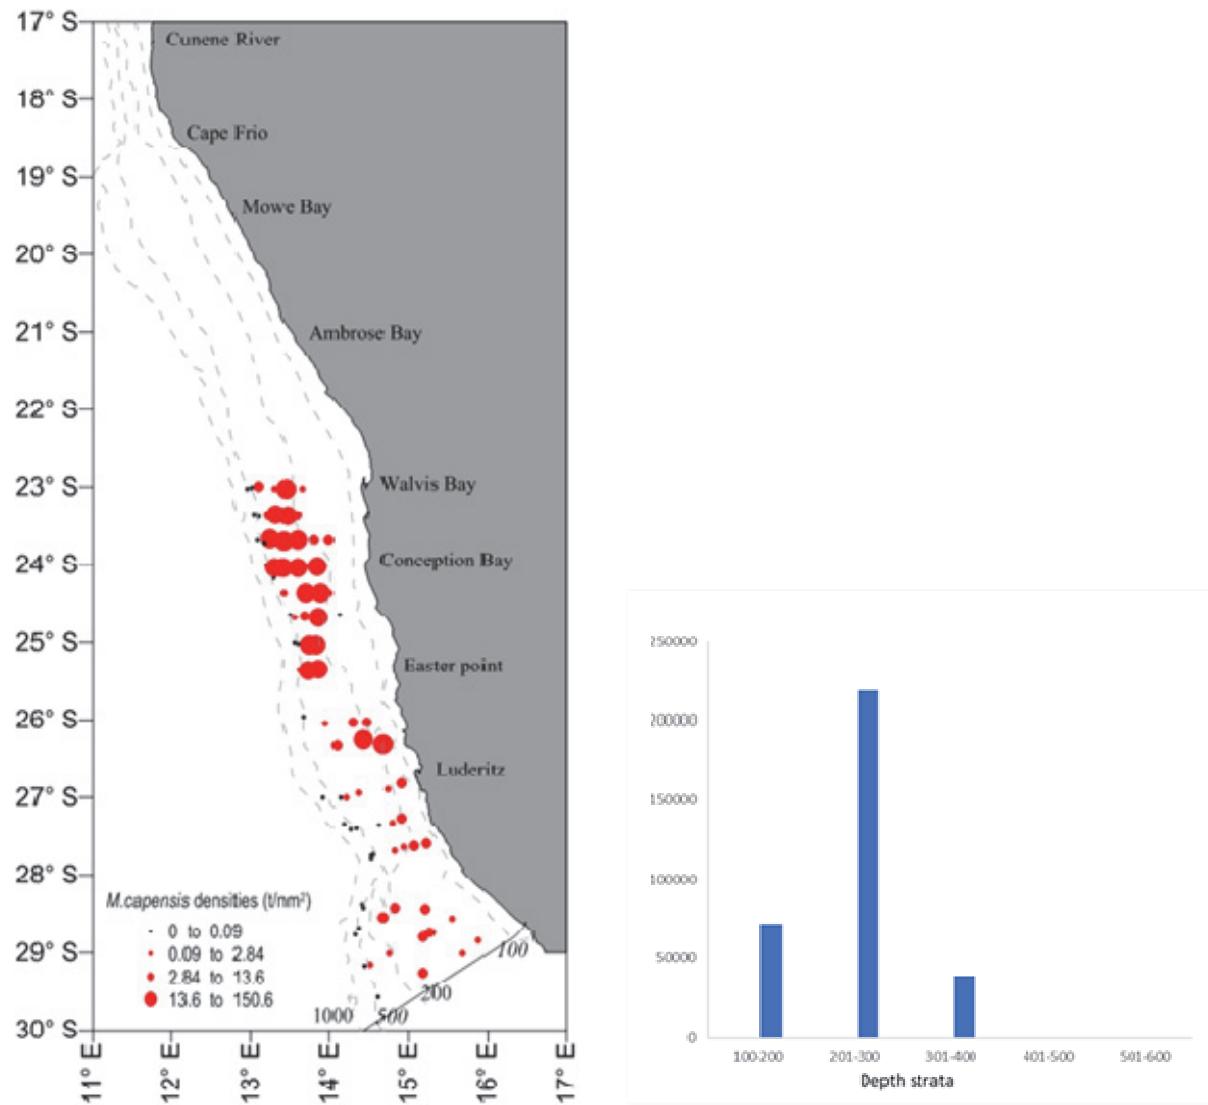

Figure 23. Spatial and depth distribution (density, tonnes/NM²) of Cape hake (*M. capensis*) off southern Namibia

The mean density for deep-water hake, *Merluccius paradoxus*, was 4.19 tonnes/NM². This species occurred at all depths to the south of Lüderitz but farther north was largely confined to waters deeper than 300 m, especially between the 300 m and 400 m isobaths (Figure 24).

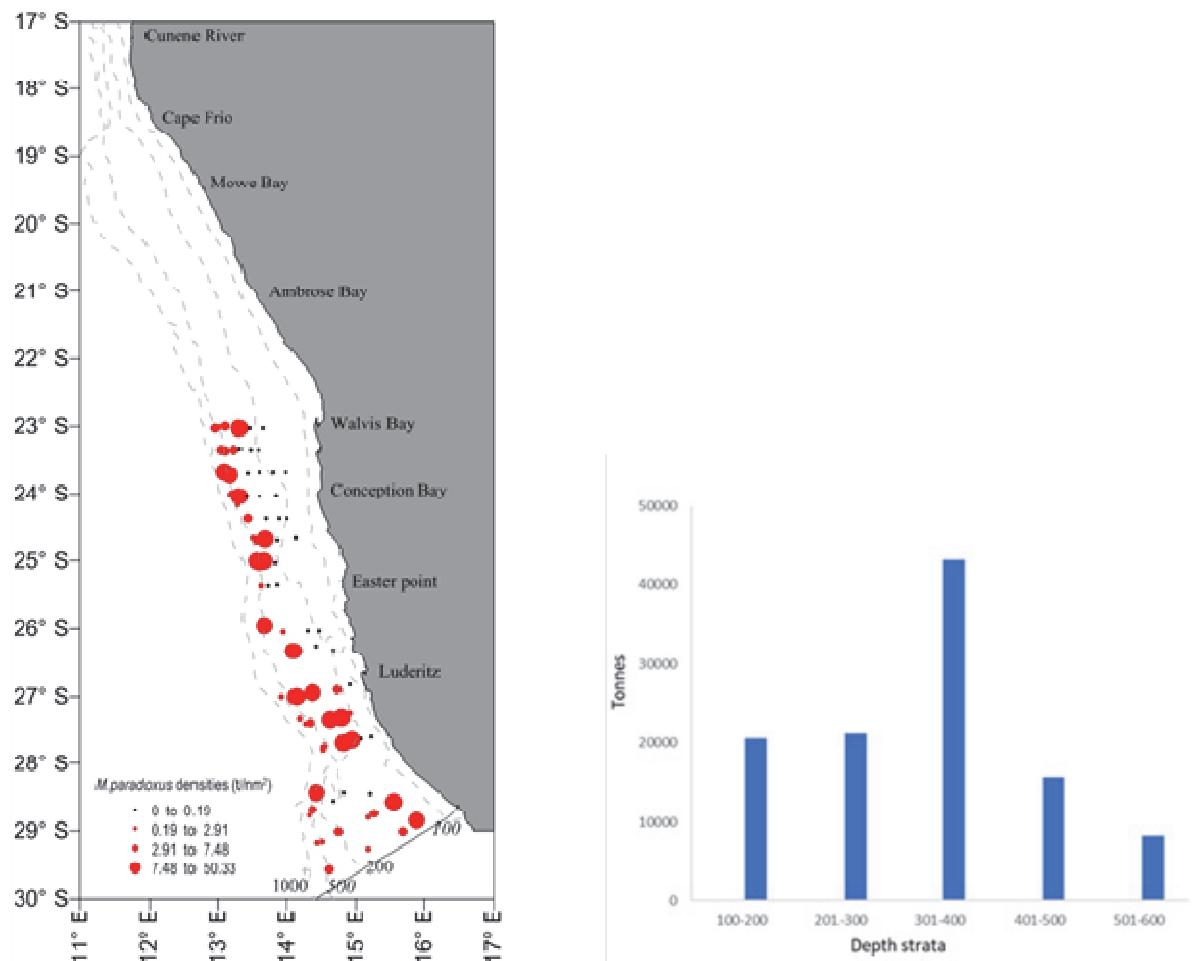

Figure 24. Spatial and depth distribution (density, tonnes/NM²) of deep-water hake (*M. paradoxus*) off southern Namibia

Significant amounts of several other targeted or potentially commercially important species were also caught at a number of stations, namely monkfish (*Lophius vomerinus*), jacopever (*Helicolenus dactylopterus*), kingklip (*Genypterurus capensis*) and Cape gurnard (*Chelidonichthys capensis*). Data on these species are presented within this report. Other commercially important species, such west coast sole (*AustroGLOSSUS microlepis*), west coast rock lobster (*Jasus lalandii*), snoek (*Thyrsites atun*) and deep-sea red crab (*Chaceon maritae*) occur in the area and within the depth zones sampled but few were caught. This was primarily because the gear is not designed to catch these species and so the few incidental specimens captured are not expected to reflect the underlying population. The data are available in the Nansis database, but they are not reported herein. Maps showing trawling locations with associated densities and the size distributions of monkfish, jacopever, kingklip and Cape gurnard are shown in Figure 25 to Figure 28.

Monkfish was sampled in small densities on the slope throughout the surveyed area, with the highest catch rates between 300 and 400 m depth (Figure 25).

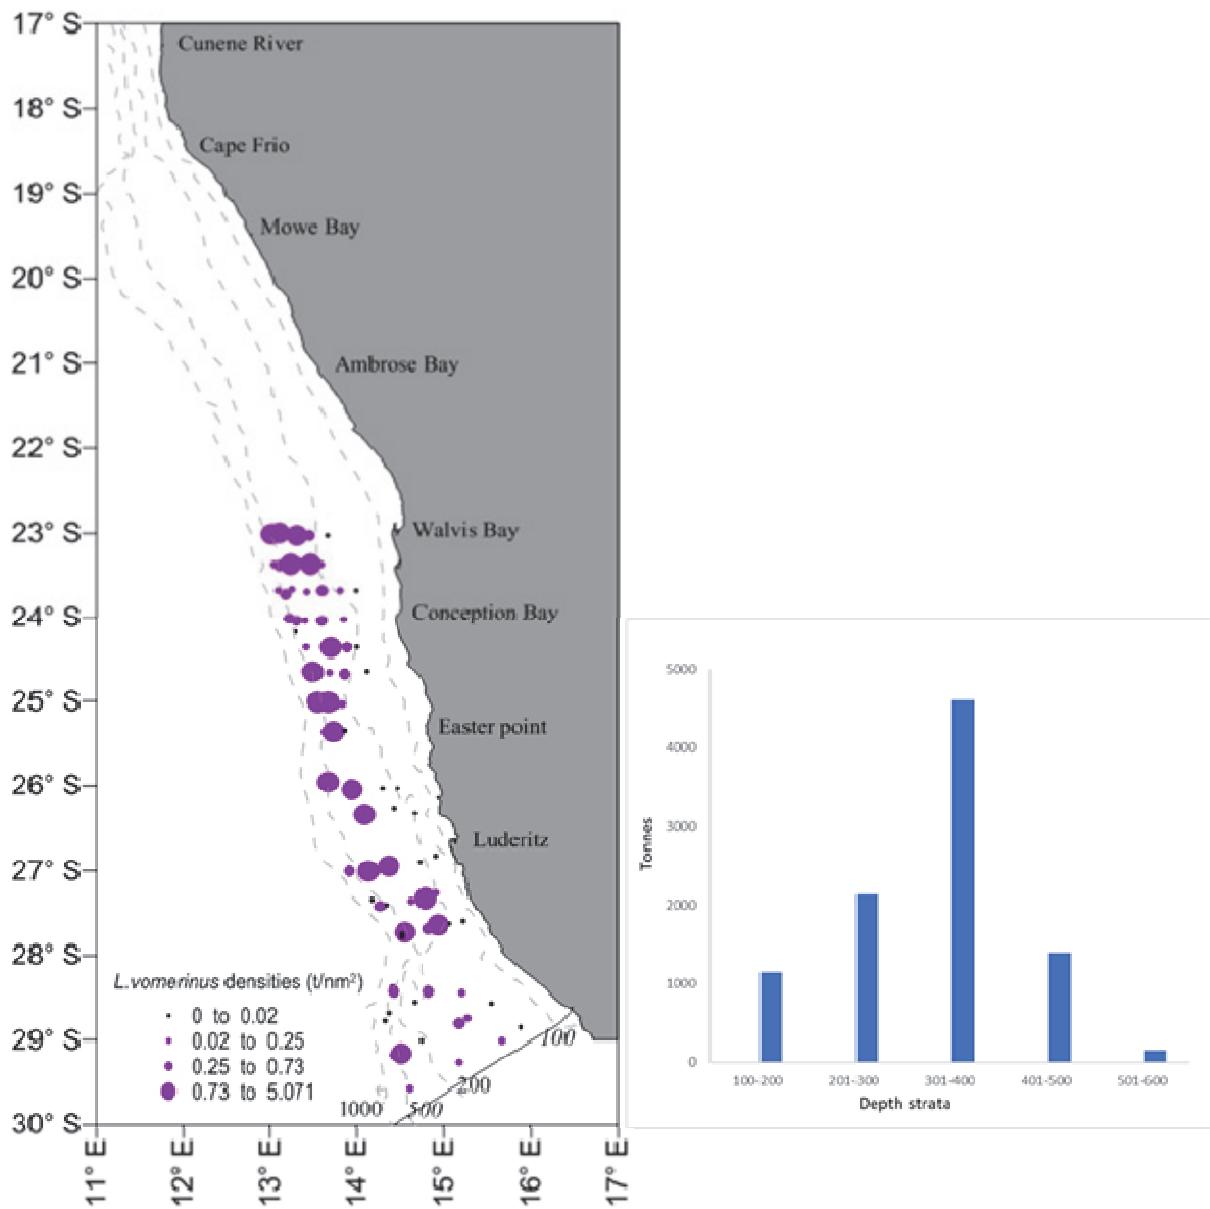

Figure 25. Spatial and depth distribution (density, tonnes/NM²) of monkfish (*Lophius vomerinus*) off southern Namibia

Kingklip were sampled offshore mostly between the 300 m and 500 m isobaths (Figure 26).

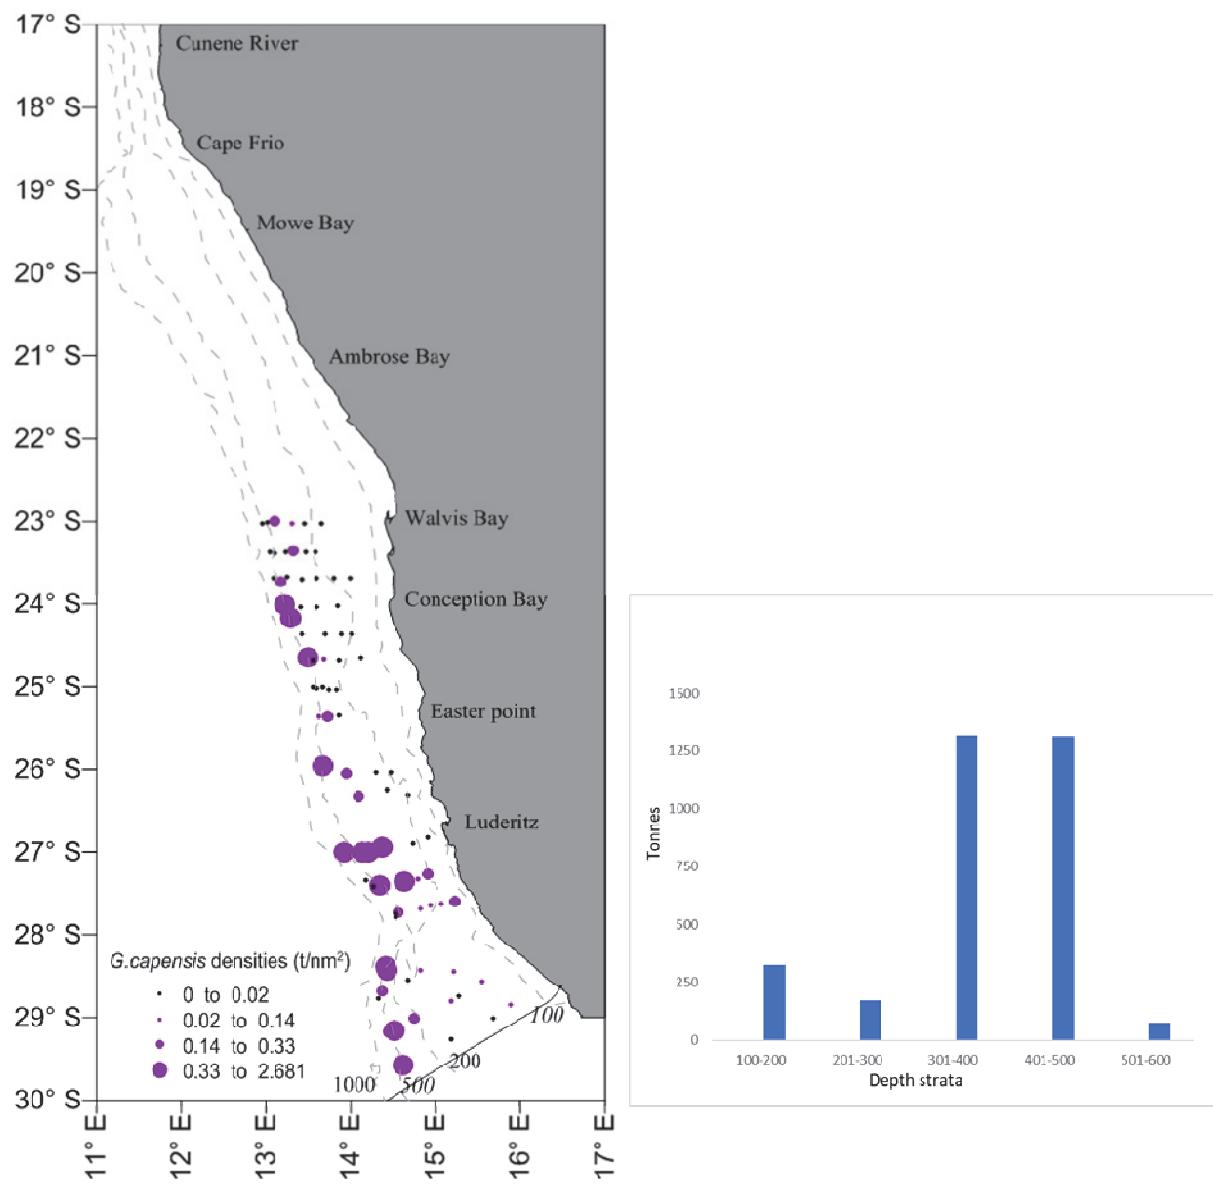

Figure 26. Spatial and depth distribution (density, tonnes/NM²) of kingklip (*Genypterus capensis*) off southern Namibia

Jacopever were sampled primarily between the 200 m and 400 m isobaths and to the north of Lüderitz (Figure 27).

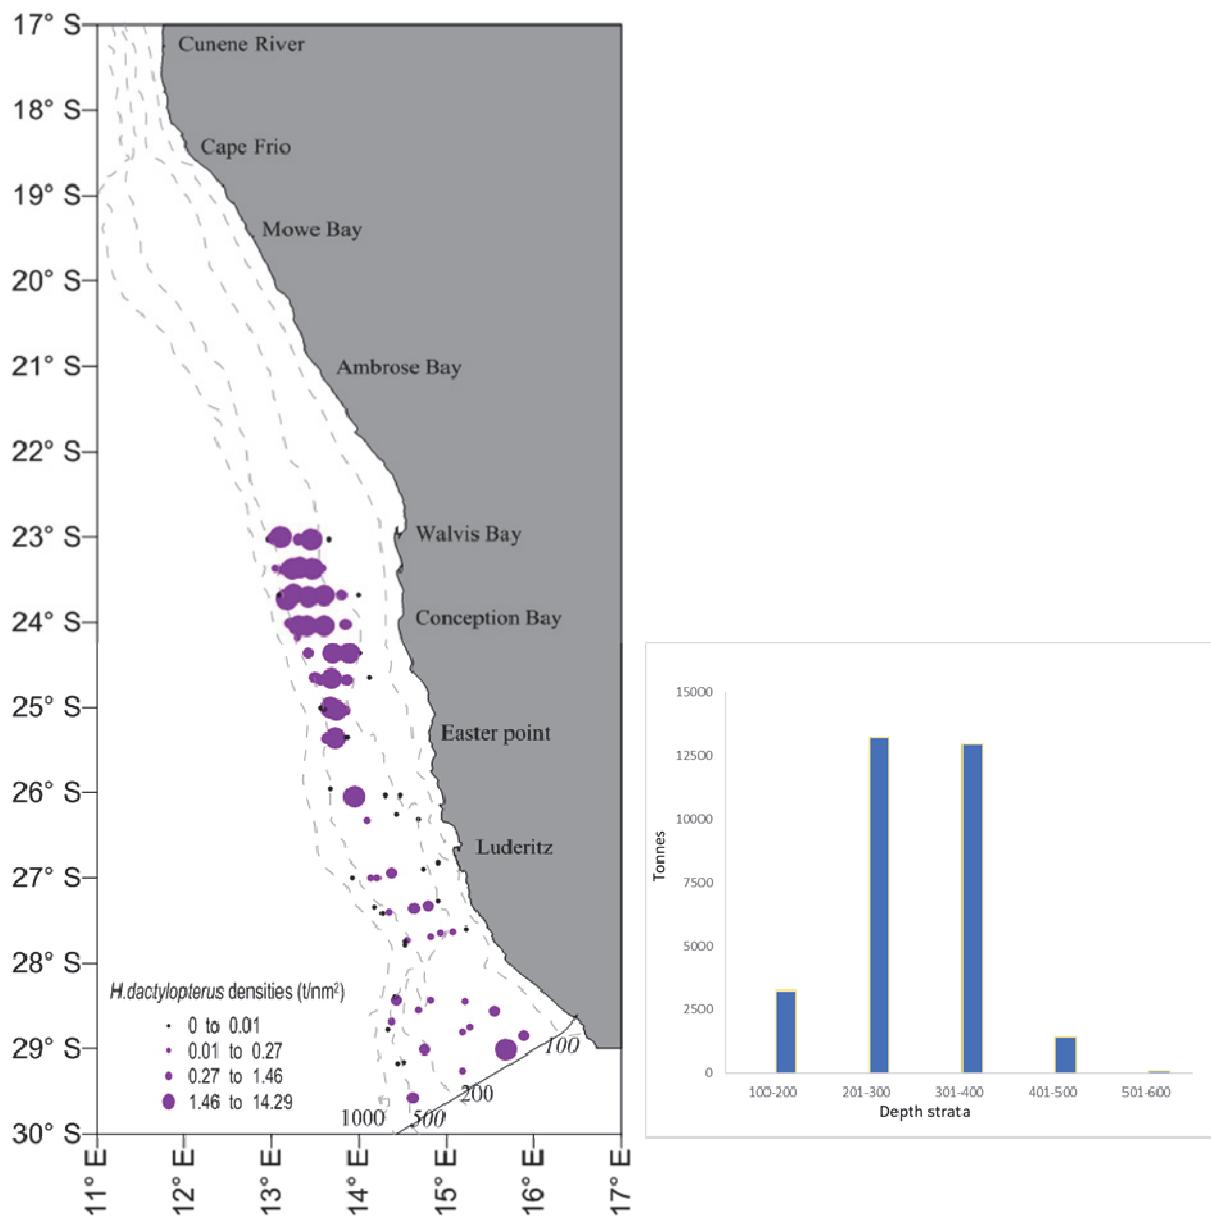

Figure 27. Spatial and depth distribution (density, tonnes/NM²) of jacopever (*Helicolenus dactylopterus*) off southern Namibia

Cape gurnard occurred primarily in the southern part of the area surveyed, and almost entirely in waters less than 200 m deep (Figure 28).

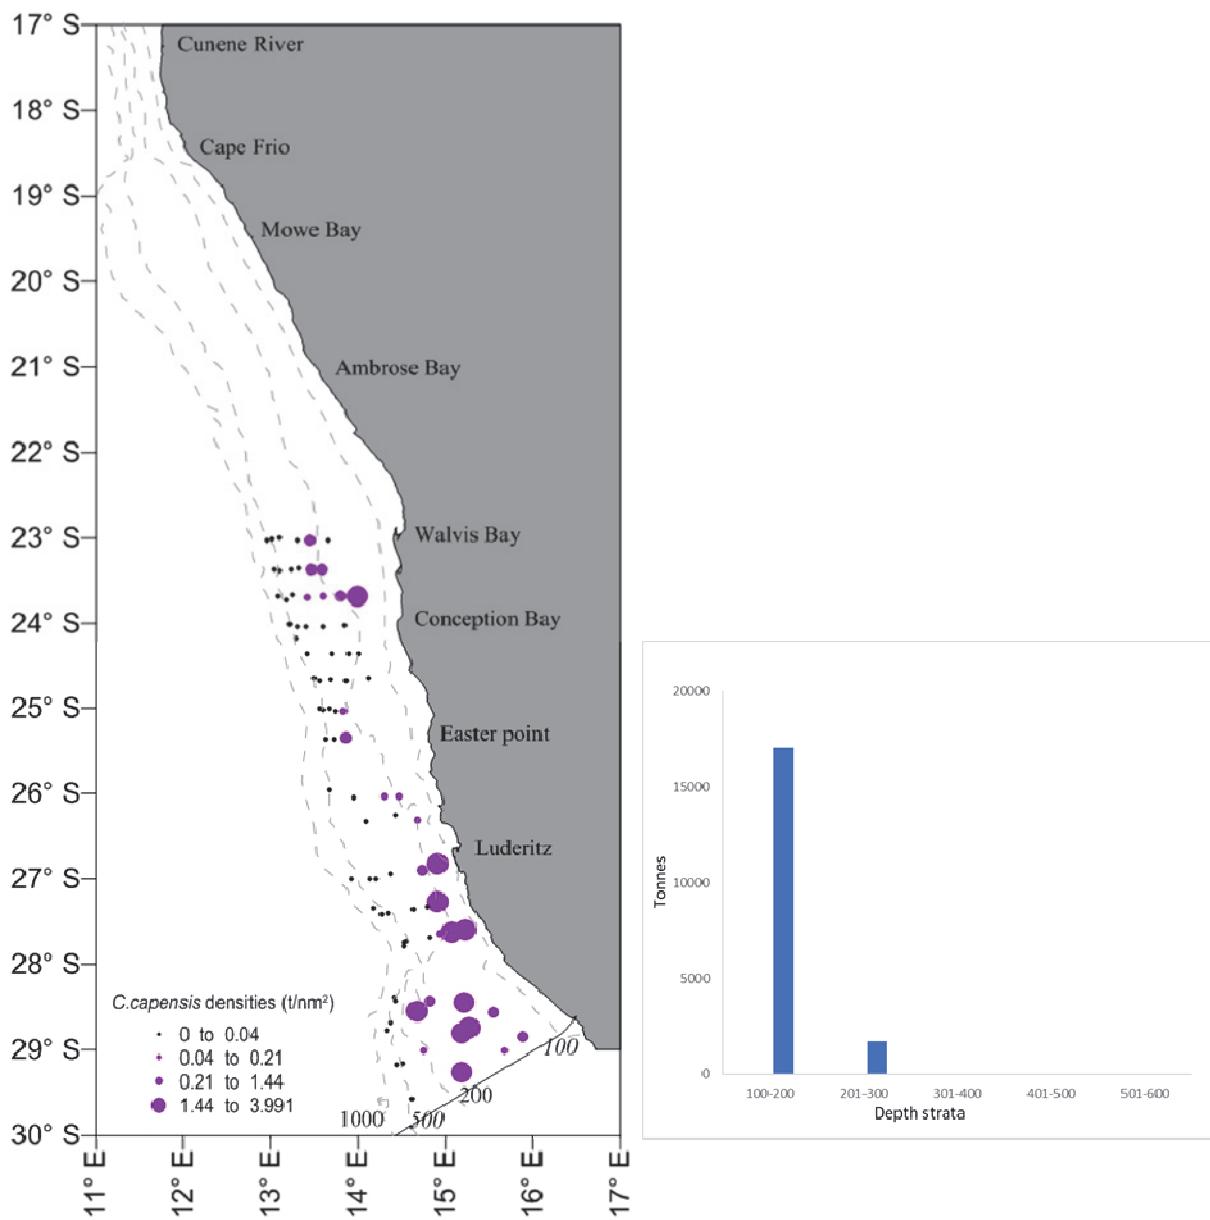

Figure 28. Spatial and depth distribution (density, tonnes/NM²) of Cape gurnard (*Chelidonichthys capensis*) off southern Namibia

Few pelagic fish species were recorded, either in the trawls or acoustically. Round herring, *Etrumeus whiteheadii*, were sampled in inshore stations to the south of Lüderitz, while a single sardine, *Sardinops sagax*, was caught at 27°35'S in 130 m water depth, with several very small sardine-like acoustic marks also seen in this area. Adult horse mackerel, *Trachurus capensis*, were sampled throughout the region (Figure 29), and acoustic registrations were often seen in the vicinity of these trawl stations. No biomass estimates of these species are provided as the survey methodology is not suitable for assessing meso- or epi-pelagic species.

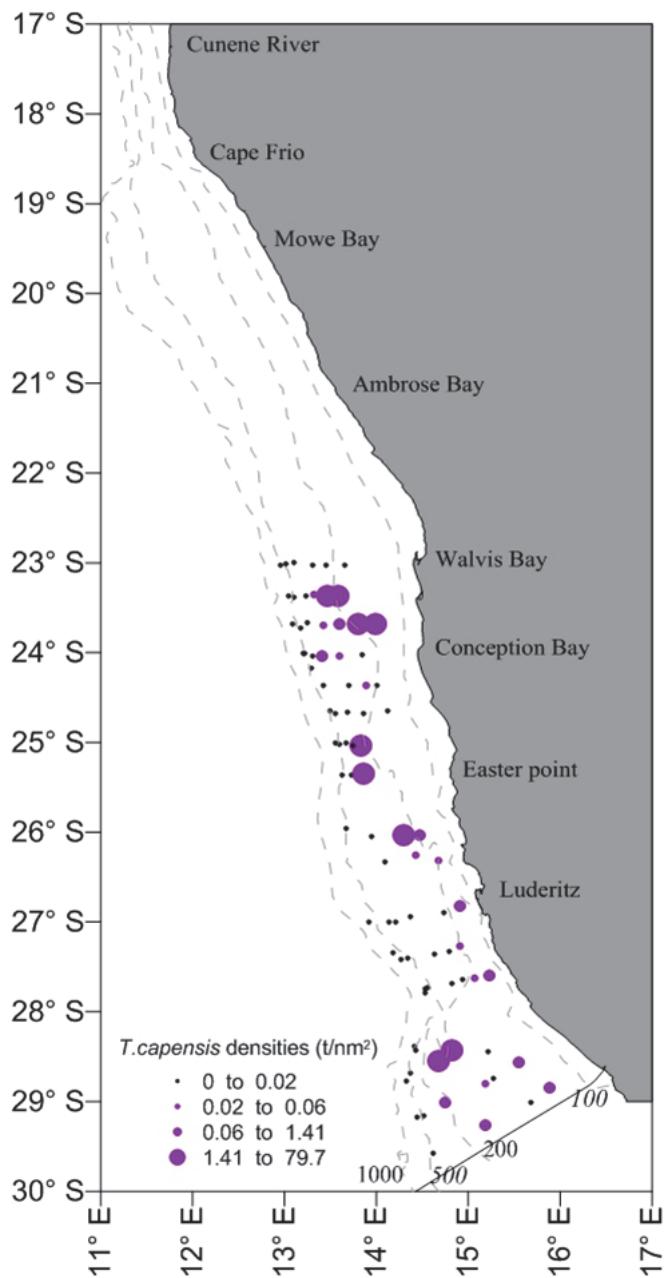

Figure 29. Spatial distribution (density, tonnes/NM²) of Cape horse mackerel (*Trachurus capensis*) off southern Namibia

3.4.2 Biomass

Biomass was calculated for the key species for each depth strata throughout the area covered by the survey. These “key” species were the two hakes and the four most common other commercially important, or potentially important, demersal species that were caught by the gear; *Lophius vomerinus*, *Genypterus capensis*, *Helicolenus dactylopterus* and *Chelidonichthys capensis*.

As noted in the Methodology section, the acoustic signal from the water column above the headrope was carefully scrutinised for each trawl. A small number of trawls indicated that a few hake (or other large swim-bladdered fish) occurred above the headrope, although it is not believed that these fish would have had added substantially to the overall estimate.

Table 10 describes the length-weight relationships of these species, as measured during the survey, and used in the calculation of biomass per length-class.

Table 10. Length-weight relationships, where length = a x weight^b, r = fit, n = sample size

Species	a	b	r	N
M. capensis	0,0062	3,0341	0,9605	3 199
M. paradoxus	0,0083	2,9606	0,9637	3 954
Lophius vomerinus	0,0188	2,9294	0,9592	357
Genypterus capensis	0,0110	3,3242	0,9495	143
Helicolenus dactylopterus	0,0177	2,9249	0,9534	987
Chelidonichthys capensis	0,0050	3,1747	0,8201	241

Table 11 presents the calculated numbers and biomass of the two hake species. The estimated biomass of *M. capensis* was 330 000 tonnes, while the biomass estimate of *M. paradoxus* was 109 000 tonnes. Figure 30 and Figure 31 show the size distributions, while Annex XI shows the total number and biomass per length-class.

Table 11. Total biomass of *M. capensis* and *M. paradoxus* in southern Namibia

Species	Numbers (millions)	Biomass (tonnes)	CV
Merluccius capensis	2 346 820	330 687	0,16
Merluccius paradoxus	928 674	108 645	0,20

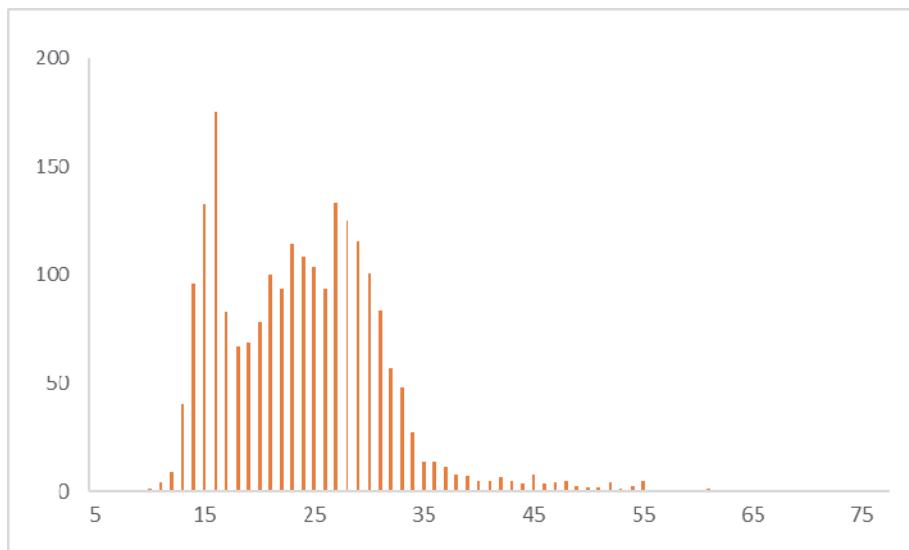

Figure 30. Size distribution of *Merluccius capensis* in the survey area (numbers in millions, raised to the total population, sample size = 3 351, from 56 trawls)

Cape hake largely consisted of a single length-group from about 20 cm to 30 cm, which are assumed to be several cohorts that have now fully recruited to the demersal component of the stock (although not necessarily to the mature breeding stock, which is considered to be fish greater than 35 cm). A further cohort, 13 cm to 18 cm, is clearly recruiting to the stock. These are presumably from the mid-year (winter) 2018 spawning. Whether this cohort is fully recruited to the demersal zone, or this represents just part of the cohort, is not known.

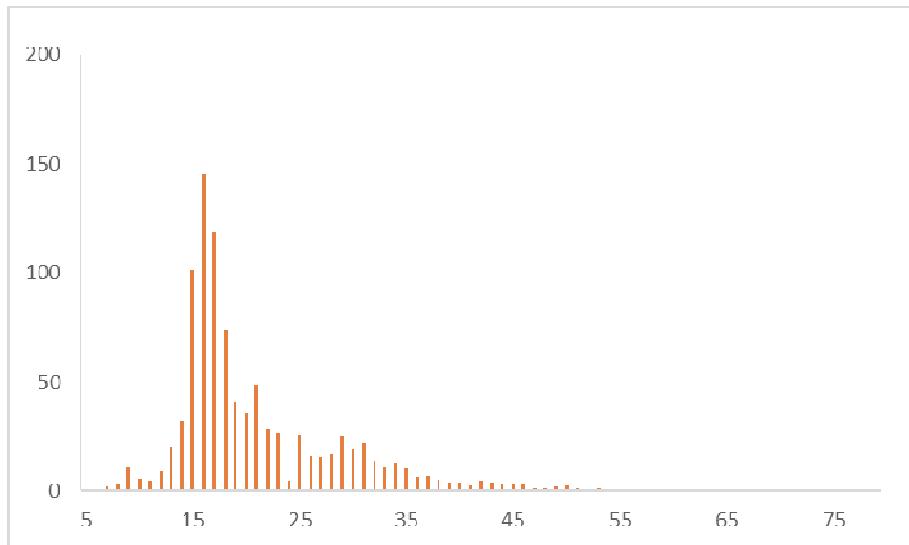

Figure 31. Size distribution of *Merluccius paradoxus* in the survey area (numbers in millions, raised to the total population, sample size = 3 724, from 45 trawls)

The deep-water hake assessed during this survey were dominated by smaller fish; between about 15 cm and 19 cm. It is assumed that these represent the newly arrived young cohort from South Africa (see Discussion).

After previous surveys, the hake data have been divided in fishable (>35 cm) and non-fishable ≤35 cm) portions in Namibia; the fish < 35 cm are considered to be recruits and should therefore not be part of the fishable stock.

While around a third by weight of both species have recruited to the fishable stock, this represents just 6% of the number of fish assessed during this survey (Table 12).

Table 12. Fishable and non-fishable components for hakes in southern Namibia

	<i>M. capensis</i>		<i>M. paradoxus</i>	
	Number (millions)	Biomass (tonnes)	Number (millions)	Biomass (tonnes)
Non-fishable ≤35	2 208 270	236 211	863 452	67
Fishable>35	138 550	94 476	65 222	41
Proportion >35 cm	6%	28%	7%	38%
Total	2 346 820	330 687	984 776	109

3.4.3 Bycatch species

Four species of the demersal “bycatch” species were recorded in sufficient quantities to warrant estimation of their abundance. Of these, Jacopever, *Helicolenus dactylopterus*, and Cape gurnard, *Chelidonichthys capensis*, had by far the largest biomasses (Table 13). These species have never been subject to a targeted fishery in Namibia. Monkfish, *Lophius vomerinus*, and kingklip, *Genypterus capensis*, have both previously been targeted but their biomasses are somewhat lower. The size distributions of these four species are shown in Figure 32 and Figure 35 (note all numbers are raised to the total estimated biomass).

Table 13. Estimated biomass of other commercially important demersal species

Species	Biomass (tonnes)	CV
<i>Lophius vomerinus</i>	9 331	0,16
<i>Genypterus capensis</i>	3 202	0,20
<i>Helicolenus dactylopterus</i>	30 914	0,21
<i>Chelidonichthys capensis</i>	18 750	0,21

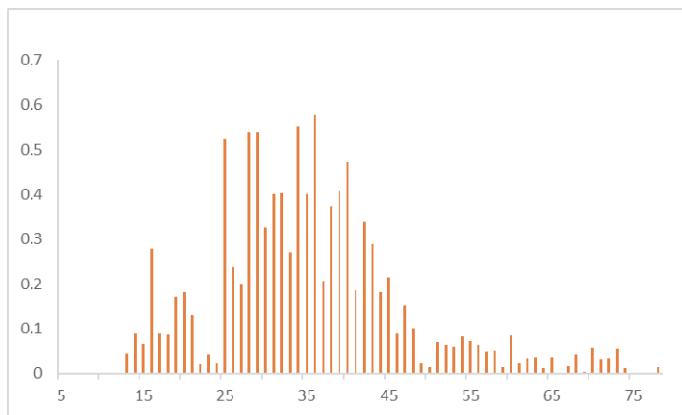

Figure 32. Size distribution of *Lophius vomerinus* in the survey area (numbers in millions)
(sample size = 357, from 54 trawls)

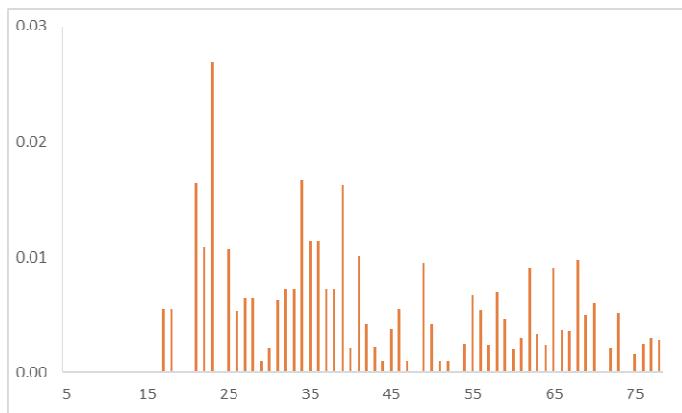

Figure 33. Size distribution of *Genypterus capensis* in the survey area (numbers in millions)
(sample size = 143, from 34 trawls)

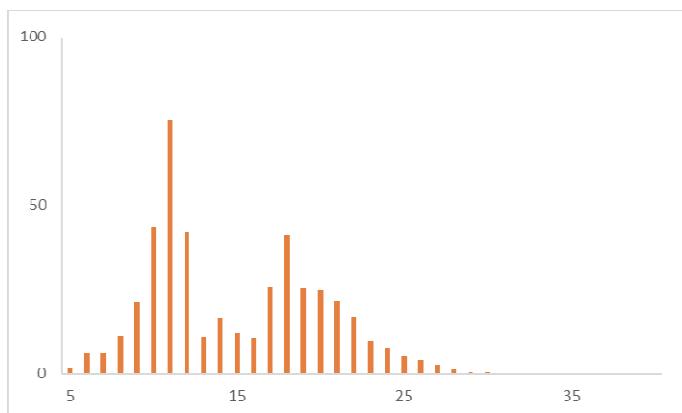

Figure 34. Size distribution of *Helicolenus dactylopterus* in the survey area (numbers in millions)
(sample size = 240, sampled from 35 trawls)

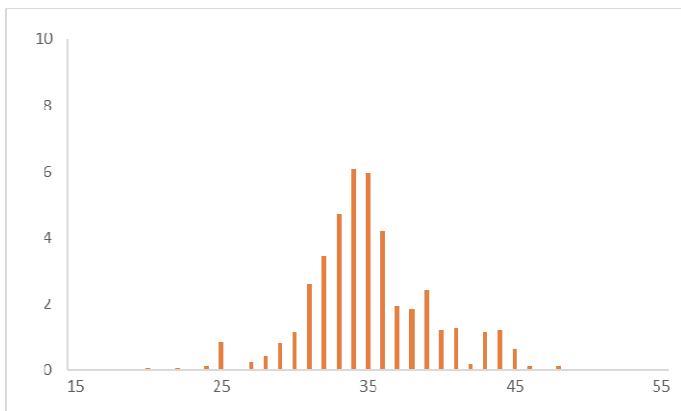

Figure 35. Size distribution of *Chelidonichthys capensis* in the survey area (numbers in millions) (sample size = 241, from 21 trawls)

3.4.4 Taxonomy

During the survey identification of fish and invertebrate species was made to the lowest taxonomic level possible by experienced taxonomists as described in the methods section. The fish species off the coast of Namibia are relatively well known and hence, not unsurprisingly, no new species were found as part of the survey.

3.4.5 Cephalopods, crustaceans and mesopelagic fish

Cephalopods, crustaceans and mesopelagic fish were collected and will be processed at the University of the Western Cape. Specimens were identified to the lowest taxonomic level when possible. Sampling only commenced at station 38 when a request to collect these species was received. Two unidentified species of Euphausiids were collected and one unidentified species of squid. *Todarodes sagittatus* were collected at 16 different stations (106 individuals in total). A total of 10 species of mesopelagic fish (Table 14) were collected, one of which was also unidentified. Species identification will take place at the University of the Western Cape.

Table 14. Mesopelagic fish species collected (from station 38 onwards), including the total number of individuals of each species collected

Species	No. of stations	Total individuals
<i>Diaphus meadi</i>	1	1
<i>Lampanyctodes australis</i>	6	45
<i>Lampanyctodes hectoris</i>	23	230
<i>Maurolicus muelleri</i>	13	124
<i>Photichthys argenteus</i>	7	37
<i>Stomias boa boa</i>	7	38
<i>Sufflogobius bibarbatus</i>	9	83
<i>Symbolophorus boops</i>	12	94
<i>Yarella blackfordi</i>	4	40
Unidentified sp.	4	34

3.4.6 Sediment samples

Benthic invertebrates were collected from sediment samples from almost all demersal trawls. For a few trawls during very rough weather it was deemed unsafe for the crew on deck to be handling the stainless-steel tubes, while the tubes were mounted incorrectly on a couple of other trawls. The benthic invertebrates were removed by filtration and provisionally identified (Figure 36 and Figure 37). 27 samples were frozen and a further 85 preserved in ethanol. All samples will be analysed at SANUMARC (University of Namibia) in Henties Bay and reported separately.

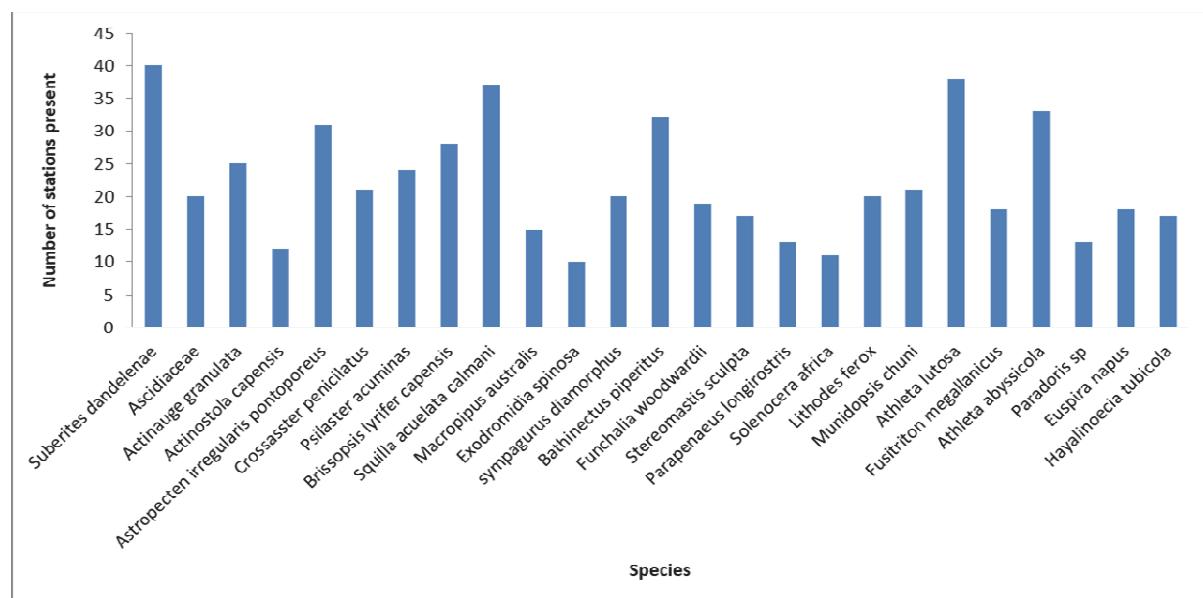

Figure 36. Frequency of occurrence of benthic organisms collected from sediment samples that occurred in more than 10 trawls

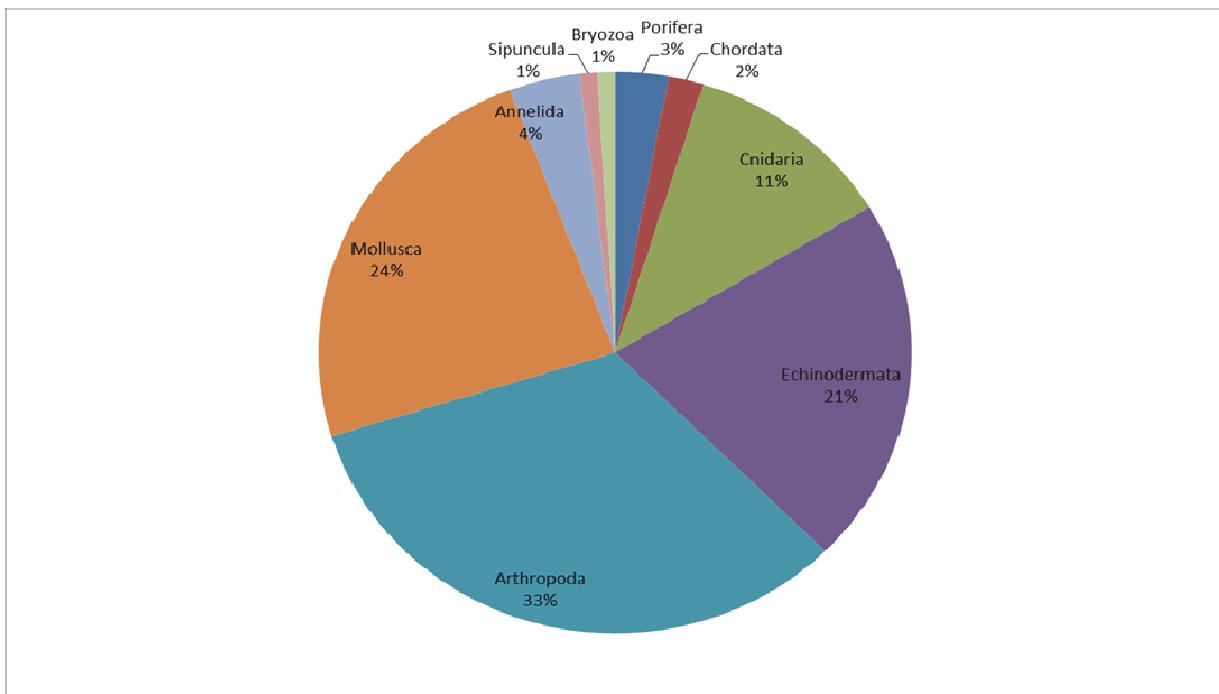

Figure 37. Species occurrence (%) per phylum of benthic invertebrates from sediment samples of all stations combined

3.5 Jellyfish

The jellyfish caught in trawls were generally much damaged. Samples of five species of scyphomedusae were collected during this cruise (Table 15). Large numbers of *Aequorea forskalea* (Figure 38 (left)) were caught but only intact individuals were collected and measured. *Chrysaora fulgida* (Figure 38 (right)) were very abundant and often made up the highest biomass in the codend. *Pelagia noctiluca* (Figure 39 (left)) were also very abundant but were only present south of 27°S. Two rarer species: *Chiropodus gorilla* and *Discomedusa lobata* (Figure 39 (right) and Figure 40) were also collected but in very low numbers (Table 15).

Table 15. Jellyfish species collected

Species	No. of stations	Total individuals
<i>Aequoria forskalea</i>	2	4
<i>Chiropodus gorilla</i>	2	2
<i>Chrysaora fulgida</i>	13	66
<i>Discomedusa lobata</i>	1	3
<i>Pelagia noctiluca</i>	8	26

Figure 40. *Discomedusa lobata*

CHAPTER 4. NATIONAL PERSPECTIVE

This chapter combines the results of both legs of the survey along the Namibian coast, Legs 2.2 and 2.4, providing a summary that is comparable to the standard Namibian hake survey reports.

The methodology used by the two surveys was essentially identical, the relevant chapters of each survey report should be consulted for the details. Any differences that are of importance are noted here.

The total survey effort is summarised in Tables 16 and 17. Nine trawls were conducted in waters deeper than 600 m;

Table 16. Survey effort - number of CTD, multinet, Manta and bottom trawl stations

Dates	4–24 April & 12–26 May
Distance (NM)	4 263
Transects	36
Bottom trawls (including “invalid” trawls)	180
CTD	228
Super stations	37
where the following samples were taken:	
Multinet	35
WP2	37
Manta	32

Several trawls were omitted from the analyses as the bottom contact time was less than 10 minutes or were deemed invalid as large amounts of rocks, mud or benthic debris were hauled up and, together with evidence from the Scanmar trawl geometry data, it was decided that the fishing efficiency of the trawl had been compromised.

Table 17. Survey effort - number of valid trawl hauls for swept-area analysis by depth strata

Effort	Depth strata (m)					Total
	100-200	200-300	300-400	400-500	500-600	
N trawl hauls	30	42	34	33	27	166
Sampling intensity (NM ² /trawl)	670	234	260	107	81	268
Area (NM ²)	20 091*	9 842	8 848	3 543	2 200	44 524

* Note that all but one trawl in the south and six trawls in the north were deeper than 150 m. Hence the inshore part of this area was not representatively sampled

4.1 Biomass estimates

Tables 18 and 19 show the number and biomass of both species of hake for the two surveys, and then the total number and biomass combined. In terms of both number and biomass, *M. capensis* provided by far the largest amount. For the whole of Namibia, a little less than one third (29 %) of the biomass of *M. capensis* was “fishable” (larger than 35 cm), but this only equated to 1% of the total population. For *M. paradoxus* the same numbers are 50% and 11%, respectively (representing fishable biomass and numbers in stock, respectively).

4.2 Species distribution

The two species of hake occur on the shelf and upper slope in the Namibian waters (Figure 41 and Figure 42). A depth-related size distribution, with the smaller fish of both species occurring shallower than the larger fish, has been recorded in both hake species. *M. capensis* typically occurs at depths from about 100 m to 350 m and overlaps with the

shallow end of the distribution range of *M. paradoxus*, which occurs mainly at depths of 300 m to 600 m. In past surveys, low catches of *M. paradoxus* have also been recorded at depths exceeding 600 m.

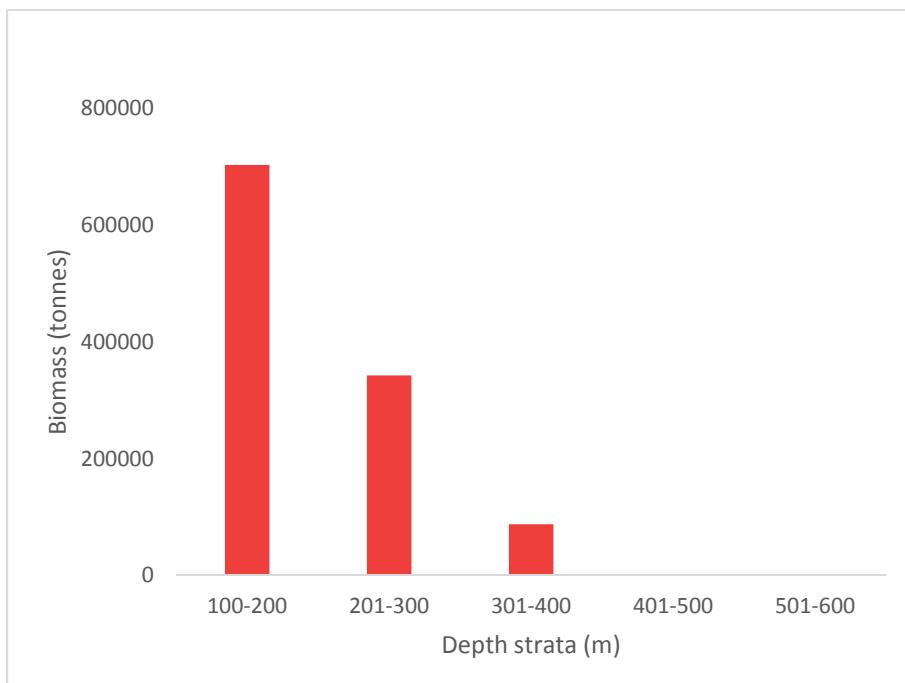

Figure 41. Biomass per depth strata for *M. capensis*

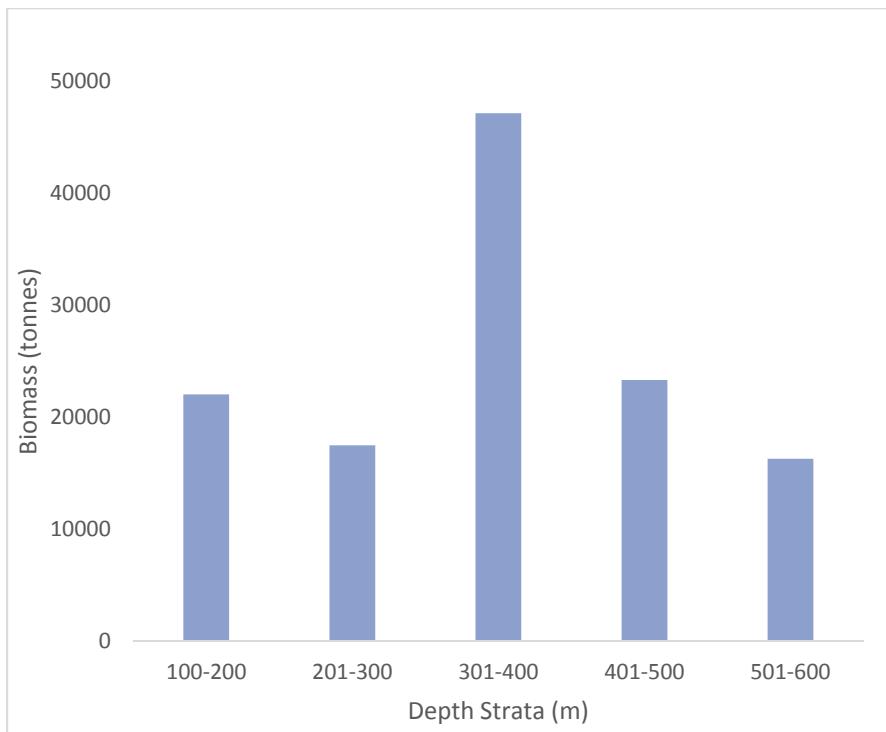

Figure 42. Biomass per depth strata for *M. paradoxus*

The catches of this survey matched previous surveys, namely that *M. capensis* was most abundant in the shallowest depth strata, all but disappearing from 400 m and deeper (Figure 43). *M. paradoxus* on the other hand occurred in all depth strata with the biomass being highest at 300-400 m depths.

During this survey, areas of high-densities for *M. capensis* ($>20 \text{ t/nm}^2$) were found primarily inshore along 200 m isobath between 22°S and 25°S and between 17°S and 19°S . For *M. paradoxus* high-density stations ($>8 \text{ t/nm}^2$) were scattered along the entire coast.

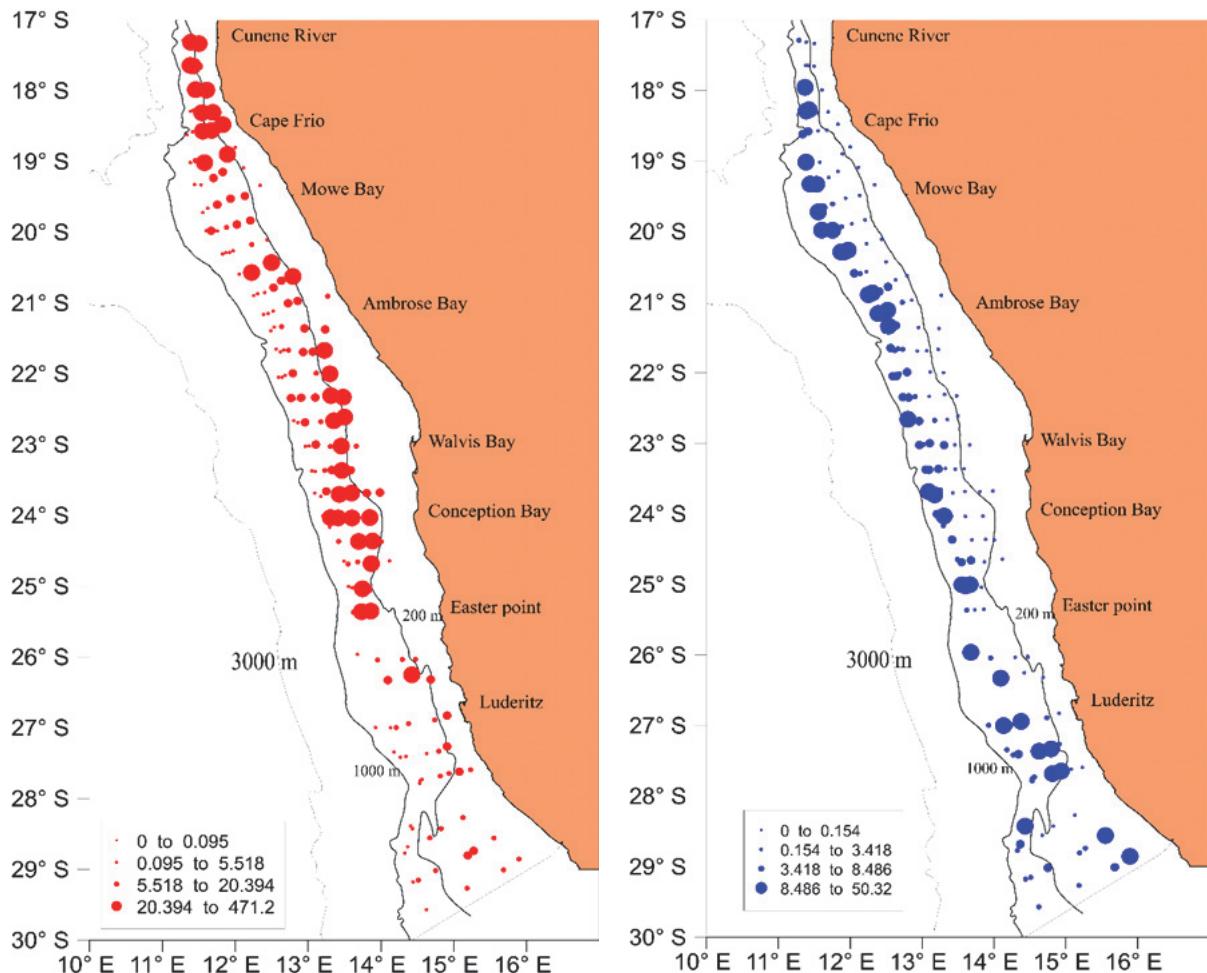

Figure 43. Density distributions (t/NM^2) for the two species of hake: *M. capensis* (left) and *M. paradoxus* (right)

4.3 Size composition

Cape hake largely consisted of a single length-group from about 25 cm to 35 cm, showing that this species consists almost entirely of a non-fishable component (Figure 44 and Figure 45). On the other hand, the biomass of deepwater hake dominated by the fishable sized fish, although by number these represented just 12.6% of the fish found in Namibian waters (Figure 46 and Figure 47). For both species, very few fish greater than 75 cm were observed; these large fish are more accessible by long liners. Further, a cohort at around 17 cm is seen in both species and these fish should be close to one year old.

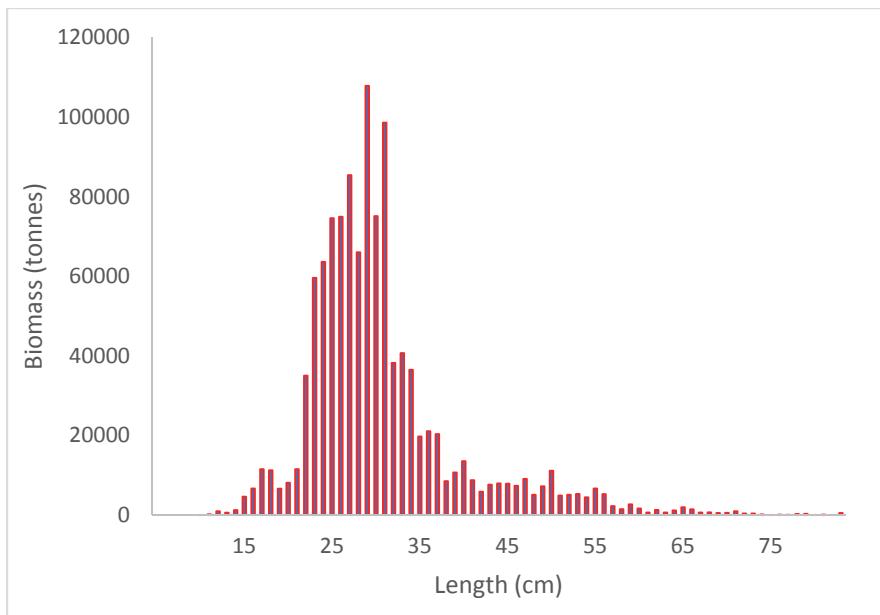

Figure 44. Size distribution in tonnes per cm of *M. capensis* for the entire Namibian region

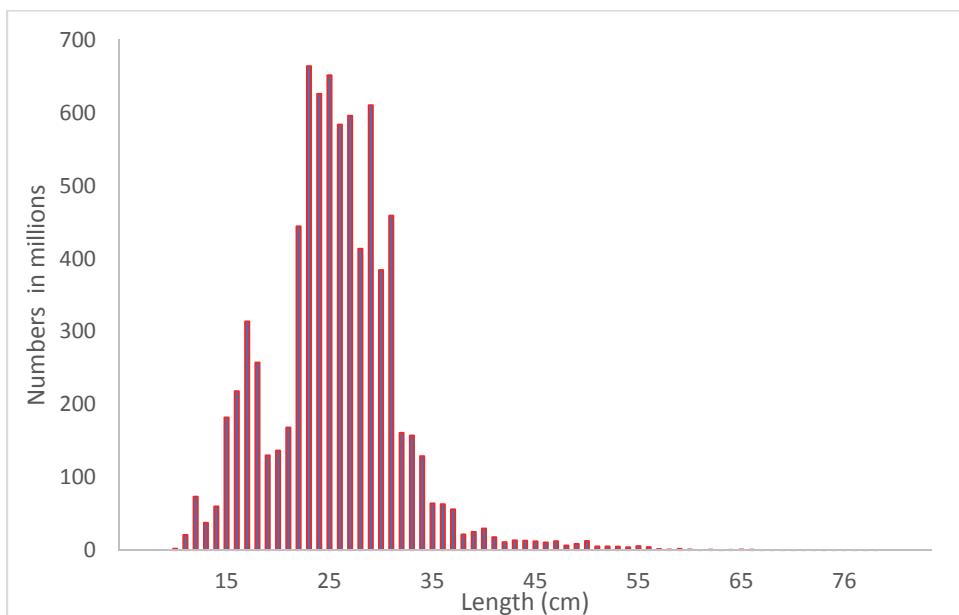

Figure 45. Size distribution in numbers per cm of *M. capensis* for the entire Namibian region

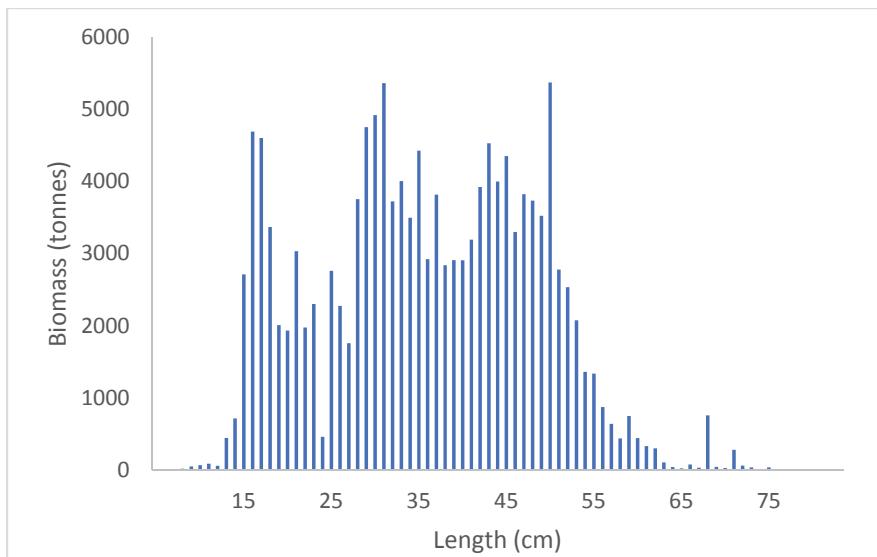

Figure 46. Size distribution in tonnes per cm of *M. paradoxus* for the entire Namibian region

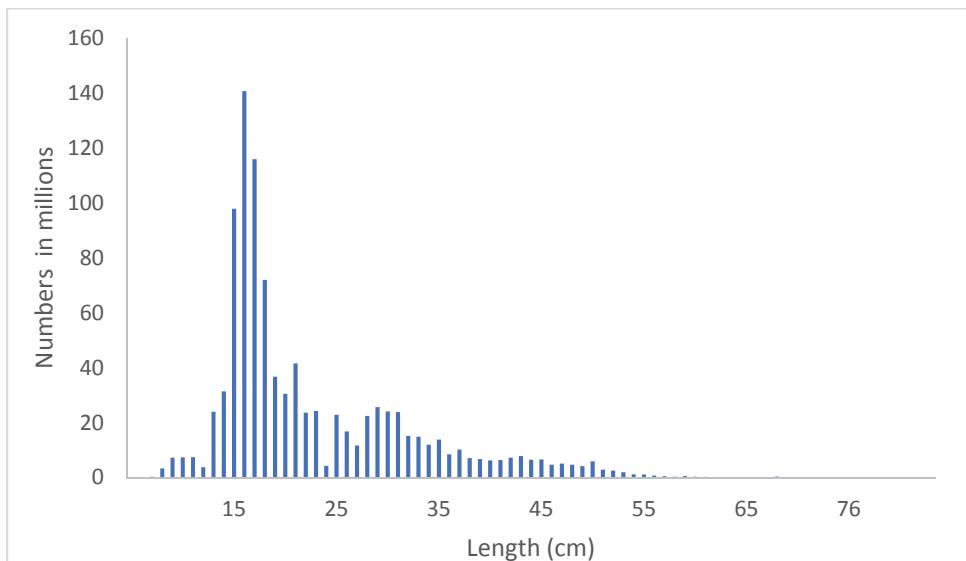

Figure 47. Size distribution in numbers per cm of *M. paradoxus* for the entire Namibian region

4.4 Recruitment estimates

Recruits to the *M. capensis* stock are estimated from the numerical abundance of the cohort of fish with a modal length of about 22 cm (between 17 cm and 27 cm, Figure 48). These recruits are assumed to be about 1.5-2 years old when caught by the survey gear. The recruitment of *M. capensis* at around 4.5 billion fish detected during the survey (the 2017-year class) was slightly higher than the long-term average. These fish are expected to fully recruit to the fishery by the second half of 2020, although some may currently be available to the bottom trawl gear. The strength of the *M. paradoxus* cohort cannot be estimated from the Namibian survey data, as the species does not appear to spawn in the Namibian waters.

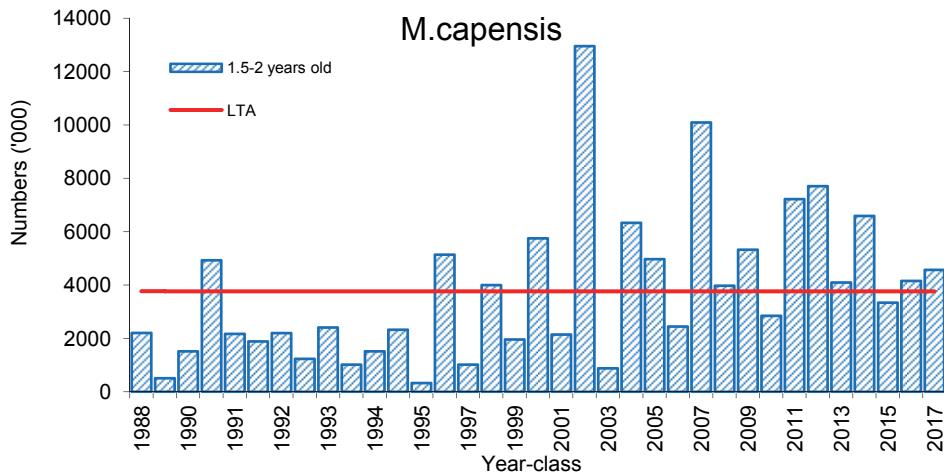

Figure 48. Estimated number of recruits (1.5-2 years old) for *M. capensis* from the hake surveys off Namibia

4.5 Survey trends of some bycatch species

Figure 49 shows the density distributions for three important hake bycatch species. The monk was well distributed along the entire Namibian coast with high densities especially in the central area and far north. Kingklip occurred primarily in the south while jacopever was found mostly from 25°S northwards.

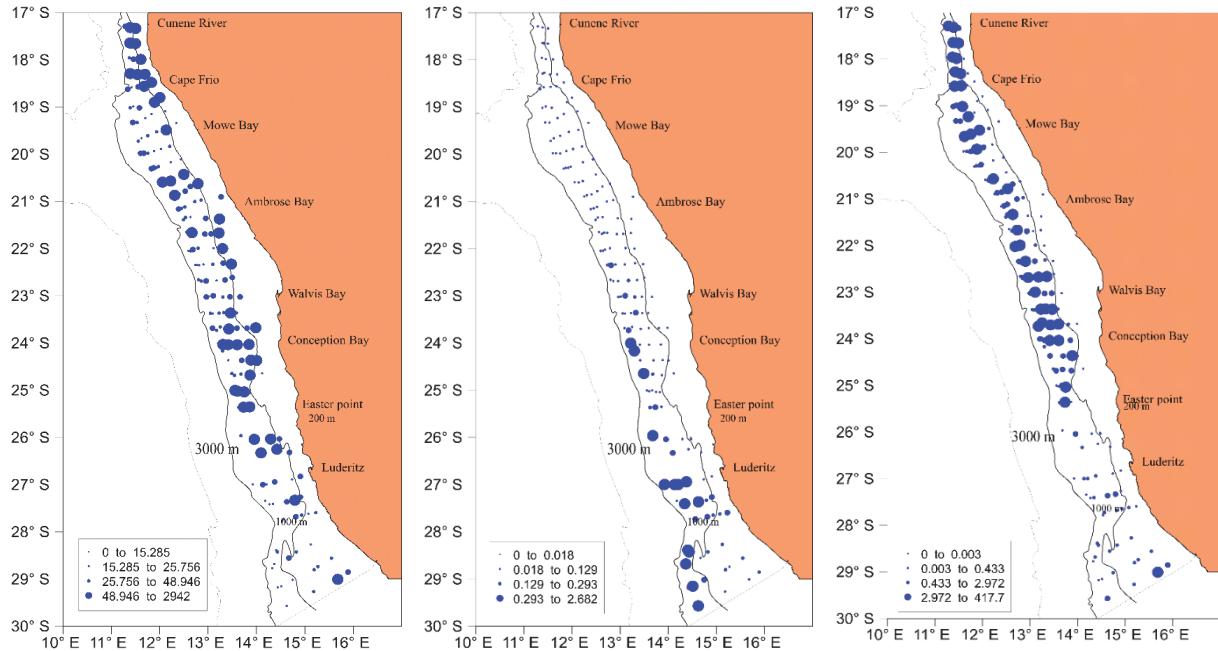

Figure 49. Density distributions (t/NM²) for monk (left), kingklip (middle) and jacopever

CHAPTER 5. DISCUSSION

This report details the methods and data collected during the first part of the 2019 hake swept-area survey of the entire Namibian coast, Leg 2.2, which covered the region from the Orange River to Walvis Bay. Much of the data collected are presented with little analysis or comment, i.e. the oceanographic, plankton, top predator, jellyfish, benthic invertebrate and hake biological data; these data will be further analysed in the context of the EAF-Nansen Science Plan.

The hake biomass data, as the primary focus of the survey, have been briefly analysed, but it is difficult to make comparisons with the long-term time-series of Namibian hake biomass estimates as the reports from previous surveys cover the entire coastline, from the Orange River to the Cunene River.

5.1 Are the hake biomass estimates comparable to previous surveys?

This survey was conducted in April; all previous surveys of the southern part of Namibia since 1996 have been conducted in January-early February. Hence this aspect has to be taken into consideration when comparing the results with previous surveys. It should also be noted that this survey was planned to provide a synoptic coverage of hake stocks in the Benguela and useful comparisons can be made at the regional level, also to unveil possible migration patterns.

In order to enhance comparability with the survey carried out in January 2018 by the R/V *Mirabilis*, the biomass data from the southern part of Namibia from the 2018 survey were re-analysed, as previously the data had only been presented for the entire Namibian area (Paulus *et al.*, 2018). The methodologies used by the 2018 survey were replicated as faithfully as possible during the 2019 survey, the main differences being that the surveys were conducted at different times of year; January compared to April, and with a different vessel.

Tables 20 and 21 show the biomass estimates from these two surveys. Clearly the estimates for both hake species for the current survey by the R/V *Dr Fridtjof Nansen* are considerably lower than those estimated by the January 2018 survey; 19% and 45% lower for *M. capensis* and *M. paradoxus* respectively.

Table 20. *M. capensis* – comparison between the January 2018 and April 2019 surveys of biomass per depth stratum in southern Namibia

Depth strata (m)	2018	2019
100-200	303 234	72 084
201-300	79 777	219 171
301-400	21 062	39 018
401-500	0	413
501-600	0	0
Total	406 091	330 687

Table 21. *M. paradoxus* - comparison between the January 2018 and April 2019 surveys of biomass per depth stratum in southern Namibia

Depth strata (m)	2018	2019
100-200	7 378	20 525
201-300	21 030	21 148
301-400	130 399	43 119
401-500	33 327	15 553
501-600	5 572	8 300
Total	199 724	108 645

These differences may of course represent real changes in the abundance of the two stocks. Equally, it is entirely possible that a portion of the fish has moved away from the southern region or was unavailable to the survey gear. For example, it is possible that the fish have moved northwards. As the current survey was conducted several months after peak water temperatures in late summer, it seems entirely plausible that the hakes have a small-scale local migration following the cooler waters southwards in summer and northwards in winter. Once the survey of northern Namibia has been completed this may become clearer. A comparison with commercial CPUE data may also be useful.

The survey covered the region from around the 150 m isobath to the shelf edge at 600 m. Fish were found at both the shallow and deep ends of the surveyed area, indicating that the zero-density line had not been reached. It is possible that significant amounts of fish were therefore outside of the surveyed region. Unfortunately, there was insufficient time to extend the survey beyond the core area of 150 m to 600 m and therefore this possibility could not be investigated.

The length frequencies of both species of hake seem to be rather different to the length frequencies of recent years (see Paulus *et al.*, 2018), although as noted previously, comparing the results from the southern part of Namibia with those from earlier surveys of the entire coastline may be misleading.

In brief, the current survey sampled a young cohort of *M. capensis* with a mean length of around 15 cm total length. It can be assumed that this cohort has not yet recruited fully to the demersal zone and so has only been partially sampled. The remainder of the fish were between 20 and 30 cm and presumably represented a series of cohorts. The majority of the fish sampled during the 2017 survey were between about 25 cm and 35 cm, while in 2018 they measured from 20 cm to 28 cm. This suggests that some of the larger *M. capensis* (>30 cm) were missing from both the 2018 and the current surveys.

With *M. paradoxus* each survey seems to sample one or more cohorts of less than about 23 cm total length, with the current survey sampling a large number of fish between 20 cm and 23 cm. The remainder of the *M. paradoxus* stock seems to be made up of a series of cohorts, with large fish greater than 40 cm being common in the 2017 and 2018 surveys (Paulus *et al.*, 2018), but rare in the current survey.

The *M. paradoxus* in Namibian waters are believed to be part of a single stock shared with South Africa, with spawning occurring off the west coast of South Africa and then juveniles migrating to Namibia, before returning to South Africa several years later to form part of the spawning stock (e.g. Strømme *et al.*, 2016; Burmeister, 2005; Iilende *et al.*, 2001; and Kainge *et al.*, 2007). The estimated biomass of *M. paradoxus* was considerably less than previous recent surveys. As the timing and extent of migration between South African waters and Namibian waters is poorly understood this reduced biomass may be a reflection of the timing of when newly arriving juveniles join the Namibian stock, and/or that a large portion of the adult stock, which might have been surveyed in January, had left on their return migration to South Africa. A comparison of the results of the survey conducted in South Africa during March 2019, Leg 2.1, with the results of this survey might help to resolve these issues.

5.2 Some brief comments on the methodology

One of the “rules” of hake surveys in Namibia is for all trawls inside the 400 m isobath to be completed during day-time as in these shallower waters Cape hake lift off the bottom during night-time and hence are unavailable to the trawl gear. It is believed that this diurnal vertical migration (DVM) is less marked in deeper waters and so deep stations can be trawled at any time of day or night (Kainge *et al.*, 2015). The Namibian surveys with R/V *Mirabilis* entail the vessel drifting or steaming for some hours mostly at night, often from around midnight to sunrise. In January “day-time” is defined as 06h00 to 20h00 (actual sunrise and sunset were 06h30 and 19h50 respectively at Walvis Bay on 15 January 2019). During this survey 07h00 to 19h00 was used (actual sunset was 07h15 to 18h47 respectively on 15 April 2019). Darkness occurs at least an hour before and after these times at depth and hence it is not surprising that the acoustic data clearly showed that the DVM started at around 17h00 each evening with fish and plankton returning to the demersal zone after 09h00 the next morning. Is it possible that the DVM changes seasonally and started farther from sunset and sunrise during the current survey than in summer? If so, during the current survey less fish would have been available to the trawl gear of stations conducted during the early mornings and late afternoons than during the summer surveys.

A final comment on the weather conditions during the survey, which were often rough, with large swells and gale-force winds making trawling difficult. Such conditions negatively impact the performance of bottom trawl gear and could potentially have affected catch rates. As these conditions are much less frequently encountered during summer months, this could be another factor partly accounting for the reduced biomass estimates.

The current methodology has been used for more than 25 years, and as such provides an invaluable time-series of biomass estimates and biological information about the Namibian hake stocks, and associated demersal community. However, these surveys are expensive in terms of both manpower and vessel costs and their use has to be maximised.

CHAPTER 6. REGIONAL SYNTHESIS

6.1 *Merluccius capensis*

Cape hake occurred from Cape Town to northern Namibia. The trawl data, with all size classes aggregated, indicate three possible separate stocks; off central Namibia, the Orange River basin and southwards and off Cape Point (Figure 50).

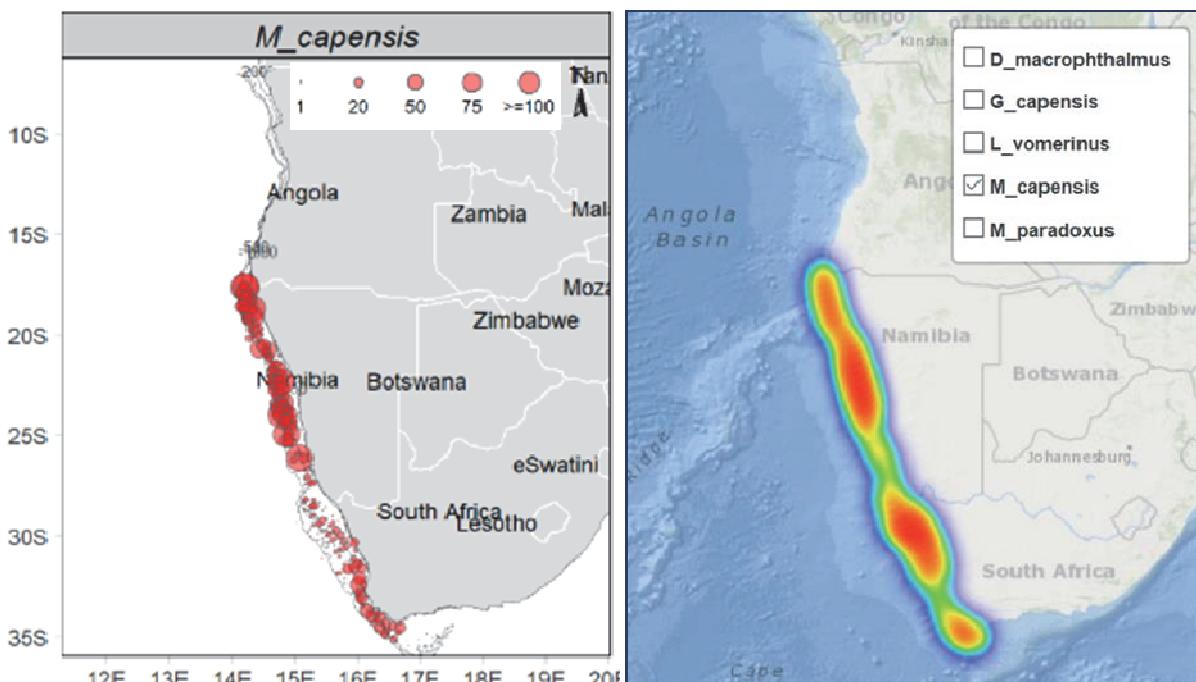

Figure 50. Distribution map for *Merluccius capensis* showing trawl catch rates (CPUE) in tonnes/NM² (left panel) and as a density heat-map (right panel)

Presenting these data in 10 cm length-classes (Figure 51) seems to support the pattern of three separate stocks. The smallest fish, in the <10 cm length-class (upper left panel), were found in small areas at the core of these three distributional areas (central Namibia, the Orange River basin and off Cape Point). As the fish grow/age these areas expand, until by the time the fish are in the 31-40 cm length-class the distribution is widespread throughout the area from Cape Point to the Cunene River (top right and middle panels). However, even at this stage there still seems to be a separation between the areas, although it would seem entirely possible that there is a transfer of fish between areas. The older fish, >41 cm (two lower panels), then seem to return to the core of these three areas, although these larger fish were less common off Cape Point.

Note that a single trawl in Angolan waters, offshore of Baia dos Tigres, contained a small quantity of *M. capensis* (5 kg/NM²) in the size range 21-55 cm. Hence, based on these data, while technically this may qualify this species as shared with Angola, for management purposes this would not normally be considered, especially if such low densities in Angolan waters are recorded in other surveys.

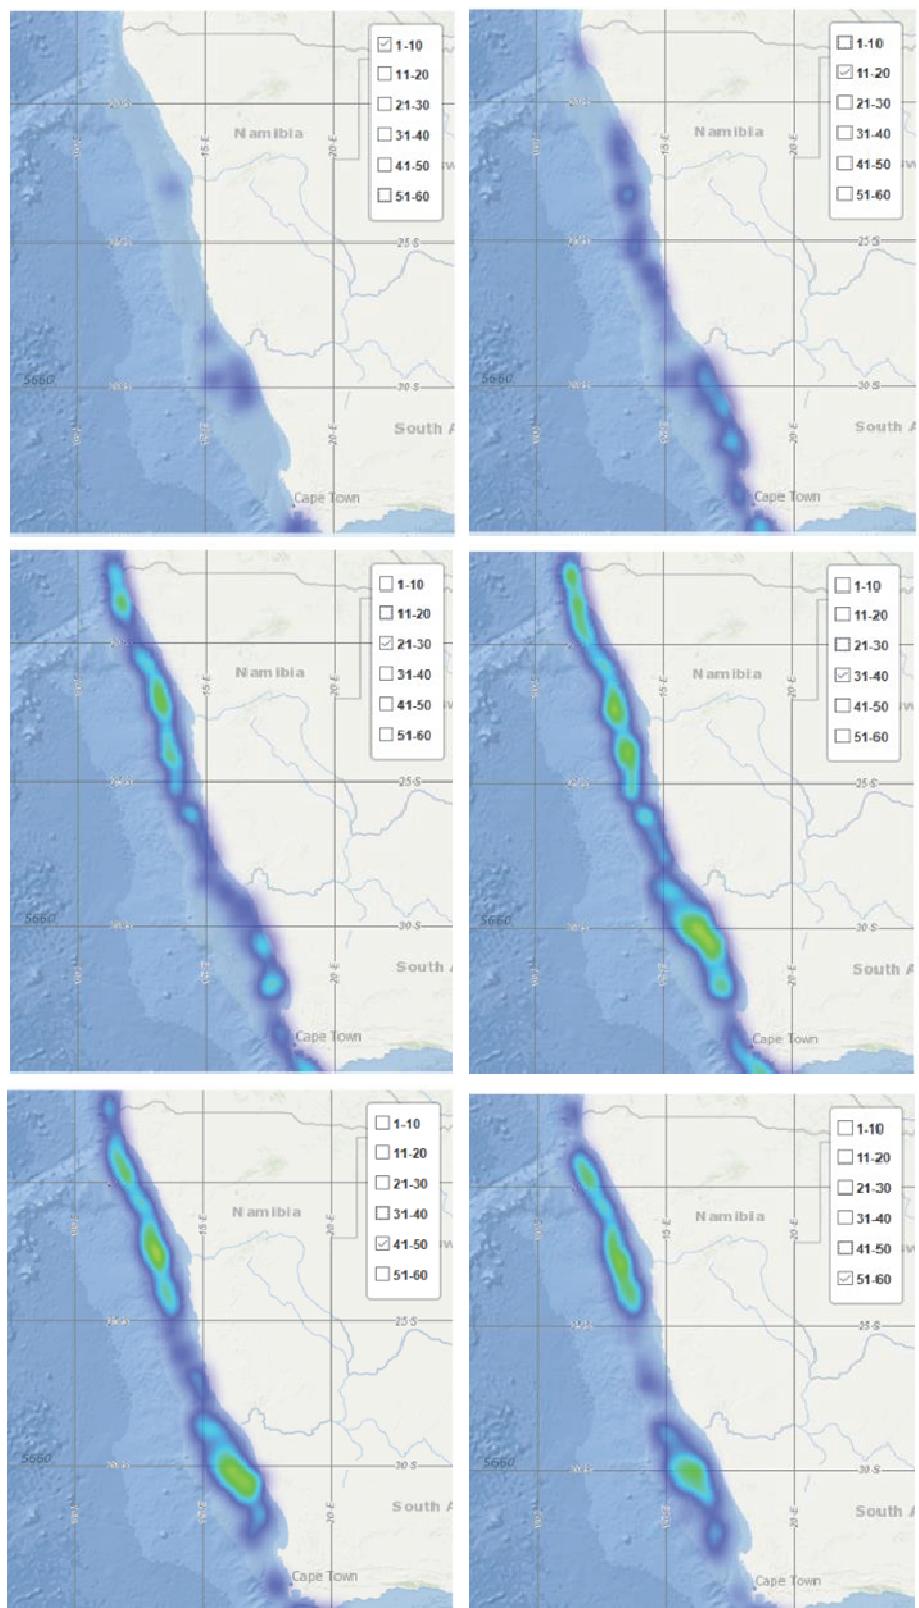

Figure 51. *Merluccius capensis* distribution in 10 cm length classes. Base map data sources: GEBCO, NOAA, CHS, OSU, CSUMB, National Geographic, DeLorme, NAVTEQ and Esri

In summary, the data collected during the March-May 2019 surveys would seem to lend some support the hypothesis that Cape hake occur as three stocks. The two southernmost areas seem to be essentially within the South African EEZ while the northern area is entirely within the Namibian zone, hence any issues of managing shared stocks may not be a concern of this species. However, more data are needed to properly assess the stock structure and migration of this species.

6.2 *Merluccius paradoxus*

Deepwater hake occurred from Cape Town to northern Namibia. The trawl data, presented with all size classes aggregated, suggest that this constitutes a single stock (Figure 52).

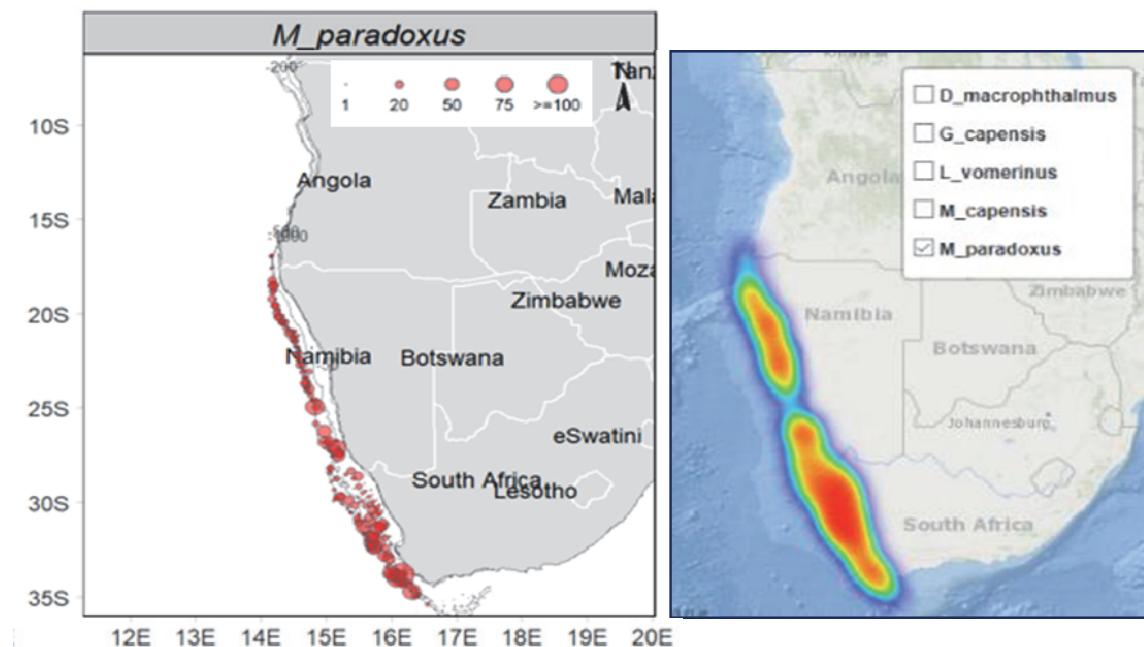

Figure 52. Distribution map for *Merluccius paradoxus* showing trawl catch rates (CPUE) in tonnes/NM² (left panel) and as a density heat-map (right panel)

When the data are analysed in more depth, by length-classes (Figure 53), a clear migration pattern emerges. All small fish, less than 11 cm, were found in South African waters, widespread between the Orange River and Cape Columbine. As the fish grew they dispersed both northwards and southwards, although few fish in the size class 11-20 cm occurred north of the Orange River border. Fish larger than this were widely spread throughout Namibia and the South African West coast.

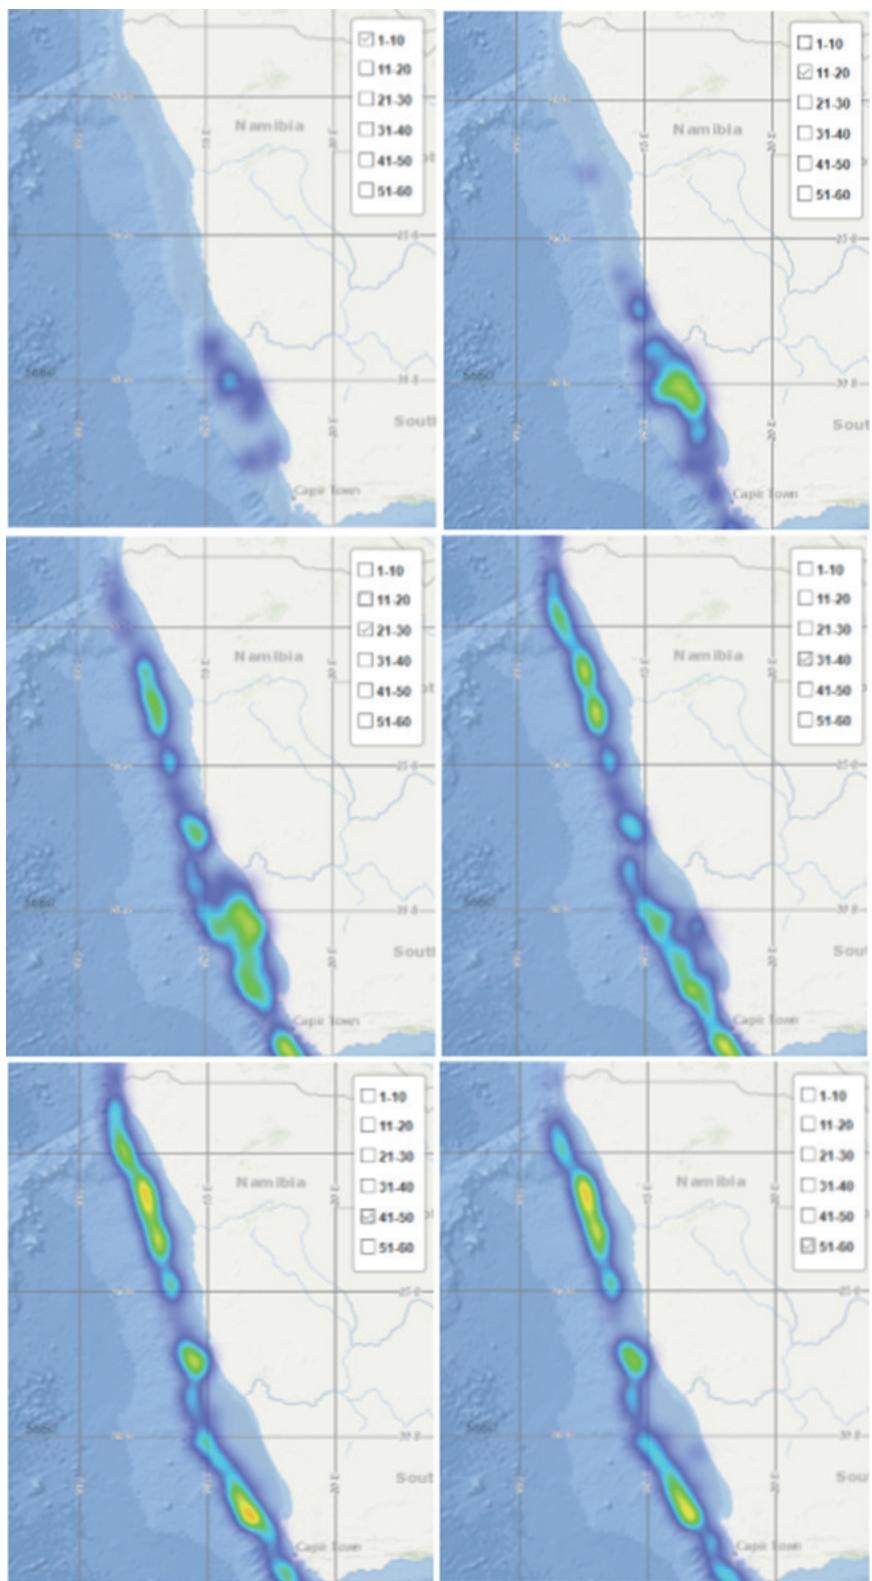

Figure 53. *Merluccius paradoxus* distribution in 10 cm length classes. Base map data sources: GEBCO, NOAA, CHS, OSU, CSUMB, National Geographic, DeLorme, NAVTEQ and Esri

This is consistent with the theory that *M. paradoxus* spawns in South Africa and then disperses into Namibia as the fish grow. However, the theory also predicts that larger fish migrate to the spawning grounds in South Africa. These data show no evidence of this.

Note that three trawls in Angolan waters, all offshore of Baía dos Tigres, contained small quantities of *M. paradoxus* (between 2 and 5 kg/NM²) in the size range 31-55 cm. While technically this may qualify this stock as shared with Angola, for management purposes such low rates of movement across the border would not normally make shared management protocols necessary. However, more data need to be analysed to ascertain whether these densities in Angolan waters are typical.

In summary, the data strongly support the hypothesis that deepwater hake occur as a single stock in the Benguela region, shared between Namibia and South Africa. It would therefore seem important for the long-term sustainability of the stock that current initiatives for collaborative approaches to research and management are further strengthened. However, further research is required to determine the full migration cycle of this species, notably whether Namibian fish return to South African waters to spawn.

6.3 Kingklip

Kingklip occurred from Cape Town to central Namibia. The trawl data, with all size classes aggregated show no clear patterns within this area of distribution beyond a dense region around 30°S to 33°S and decreasing densities to the north and south of this (Figure 54).

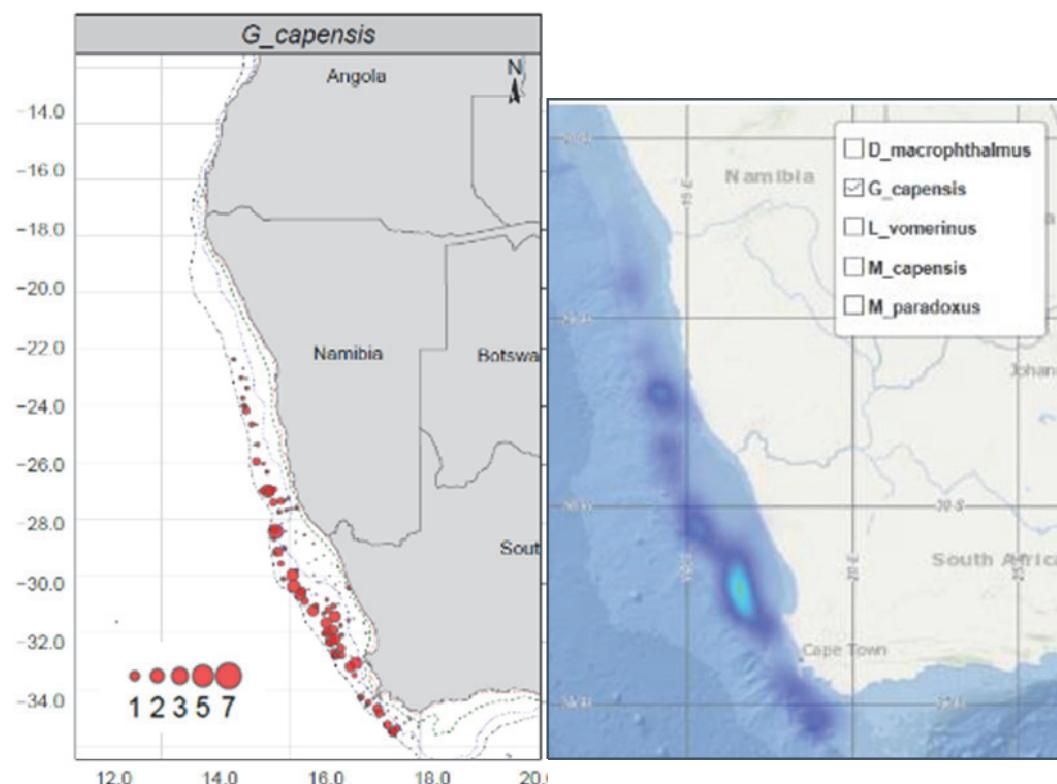

Figure 54. Distribution map for *Genypterus capensis* showing trawl catch rates (CPUE) in tonnes/NM² (left panel) and as a density heat-map (right panel)

When the data are presented in 10 cm length-classes (Figure 55) several possible patterns emerge. The smallest fish captured, in the 11-20 cm length-class, were found off the Orange River. By the time the fish had grown to 21-30 cm and 31-40 cm a second area, off Cape Point, was evident, suggestive of that the Orange River may be a spawning and/or recruitment area, some of these fish then recruiting to Cape Point. By the time the fish reached 41 cm and larger the population had expanded into the central West Coast region and also northwards into central Namibia. This species, based on the limited evidence presented here, appears to be a shared stock, albeit mostly occurring in South African waters.

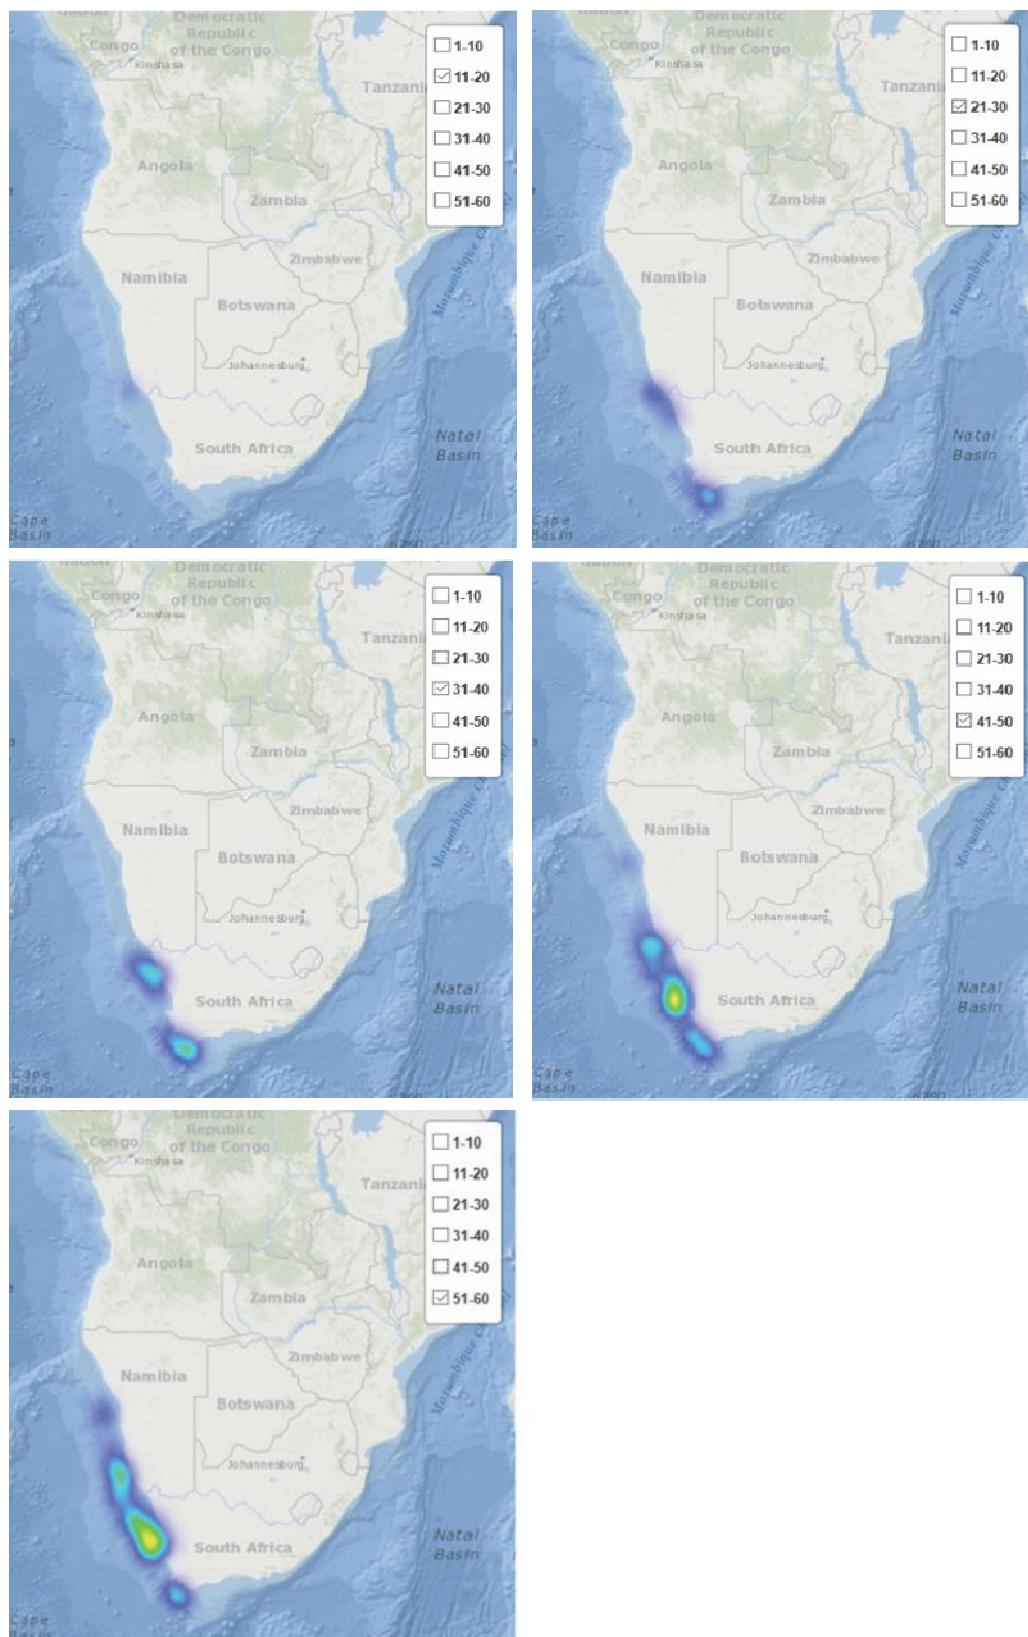

Figure 55. *Genypterus capensis* distribution in 10 cm length classes. Base map data sources: GEBCO, NOAA, CHS, OSU, CSUMB, National Geographic, DeLorme, NAVTEQ and Esri

6.4 Monk

Monk seems to have a continuous distribution from Cape Town to northern Namibia, although a lower density around the Lüderitz upwelling cell could indicate some stock separation (Figure 56).

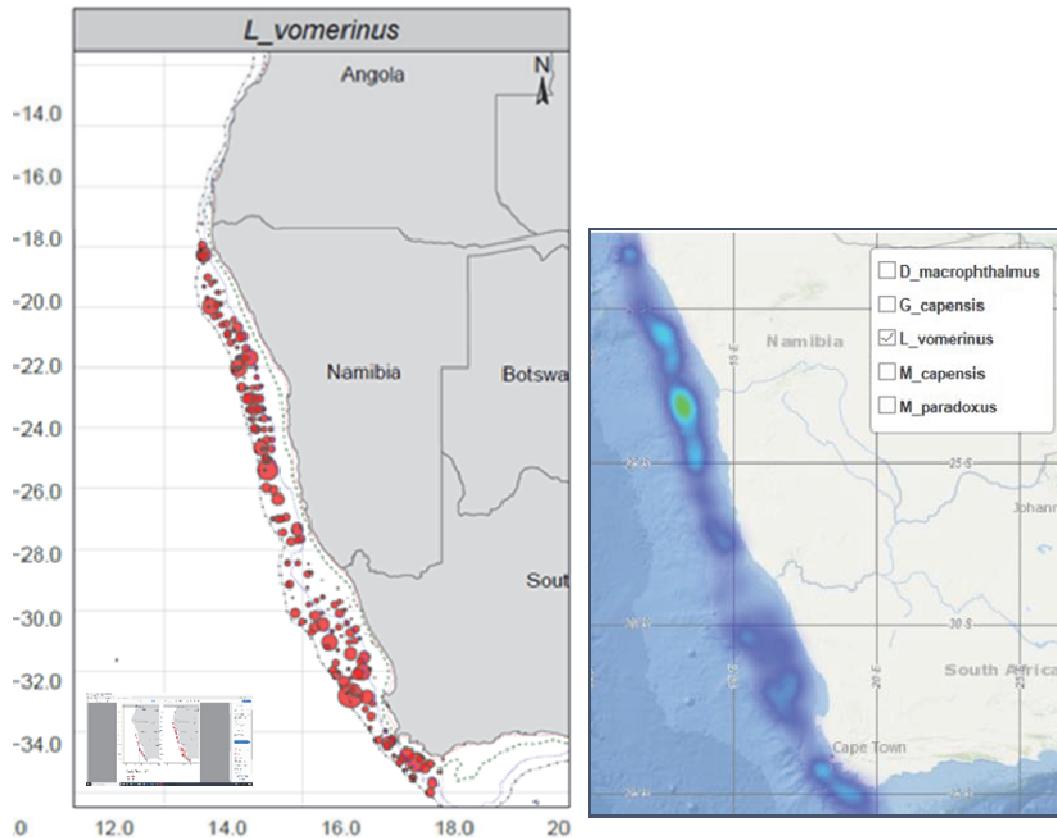

Figure 56. Distribution map for *Lophius vomerinus* showing trawl catch rates (CPUE) in tonnes/NM² (left panel) and as a density heat-map (right panel)

When the data are presented in 10 cm length-classes (Figure 57) two possible zones of recruitment seem to be present; one in central Namibia and a second off the South African West coast (upper two panels). These expand as the fish mature, with monk greater than 31 cm found throughout the Namibian and South African coasts. Whether this expansion of range results in a mixing of fish from these two recruitment areas, and hence this represents a single stock, is of course unknown. As this has consequences for management of this species further investigation should be undertaken.

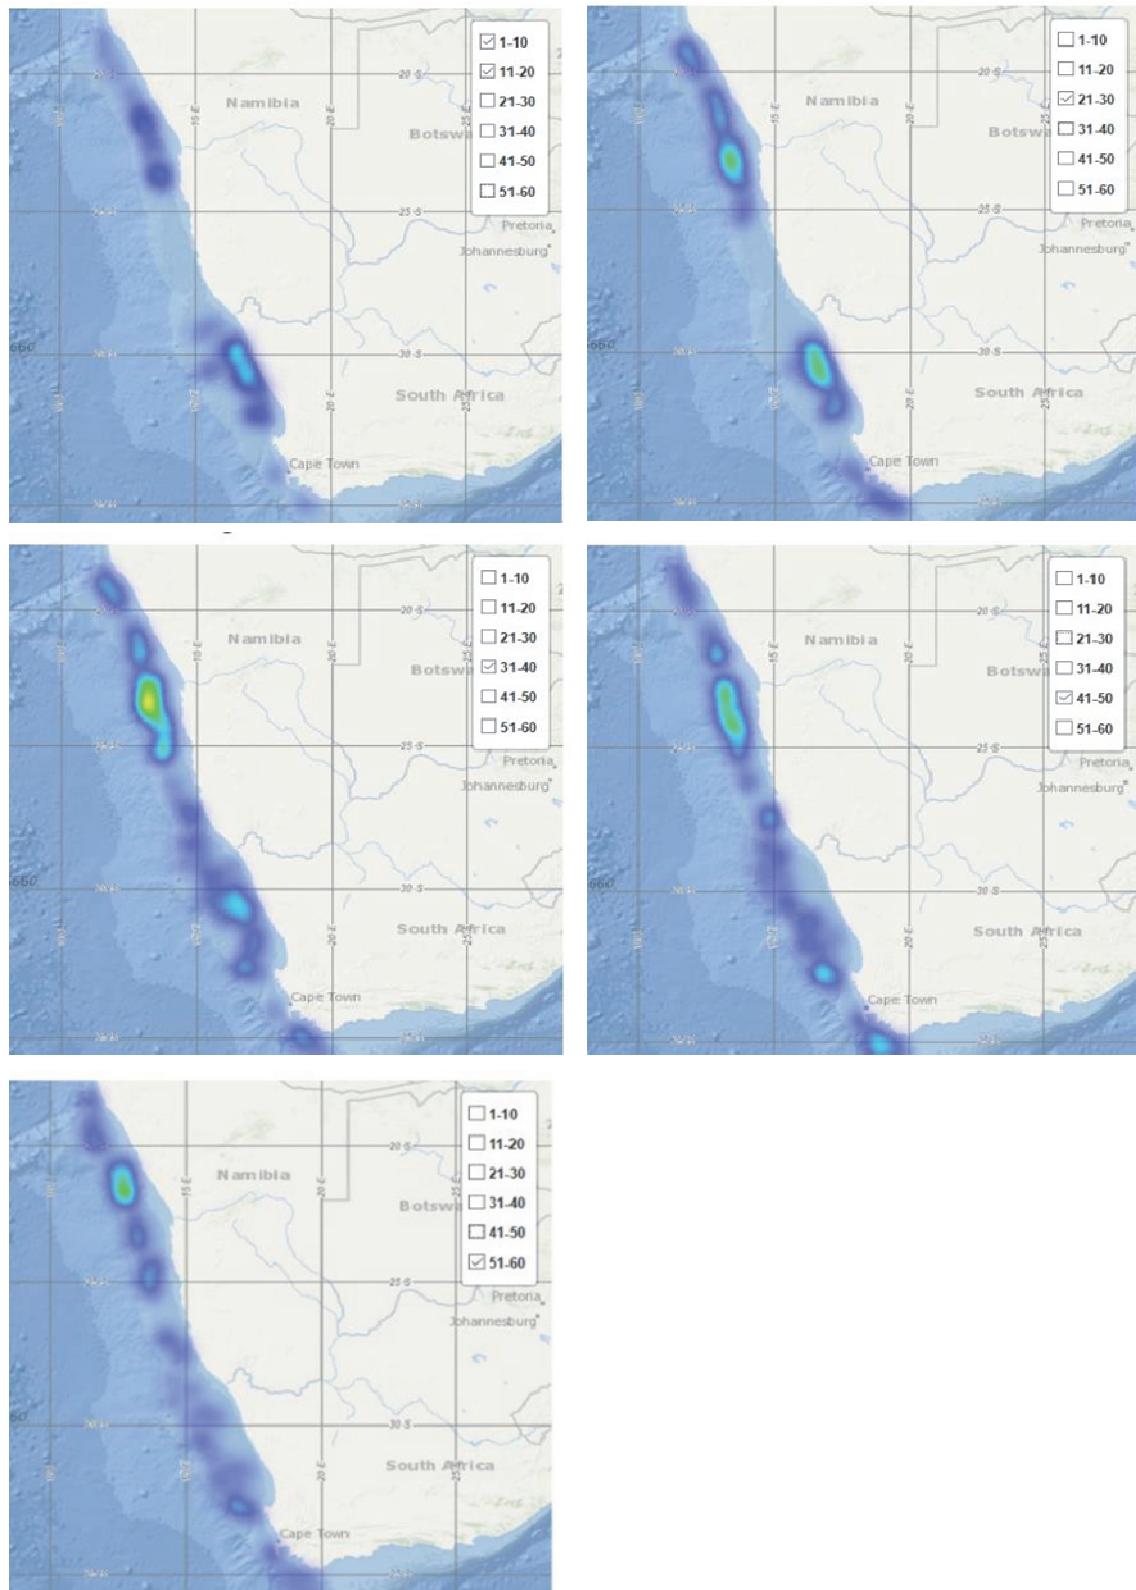

Figure 57. *Lophius vomerinus* distribution in 10 cm length classes. Base map data sources: GEBCO, NOAA, CHS, OSU, CSUMB, National Geographic, DeLorme, NAVTEQ and Esri

6.5 Dentex

The large-eye dentex (*Dentex macrophthalmus*) occurred from the coastline up to 300 m along the Angolan coast as far north as Luanda. The highest concentration was observed in the southernmost part of Angola and northern Namibia, indicating that the species is not only typical of the Benguela System, but clearly has a transboundary distribution (Figure 58).

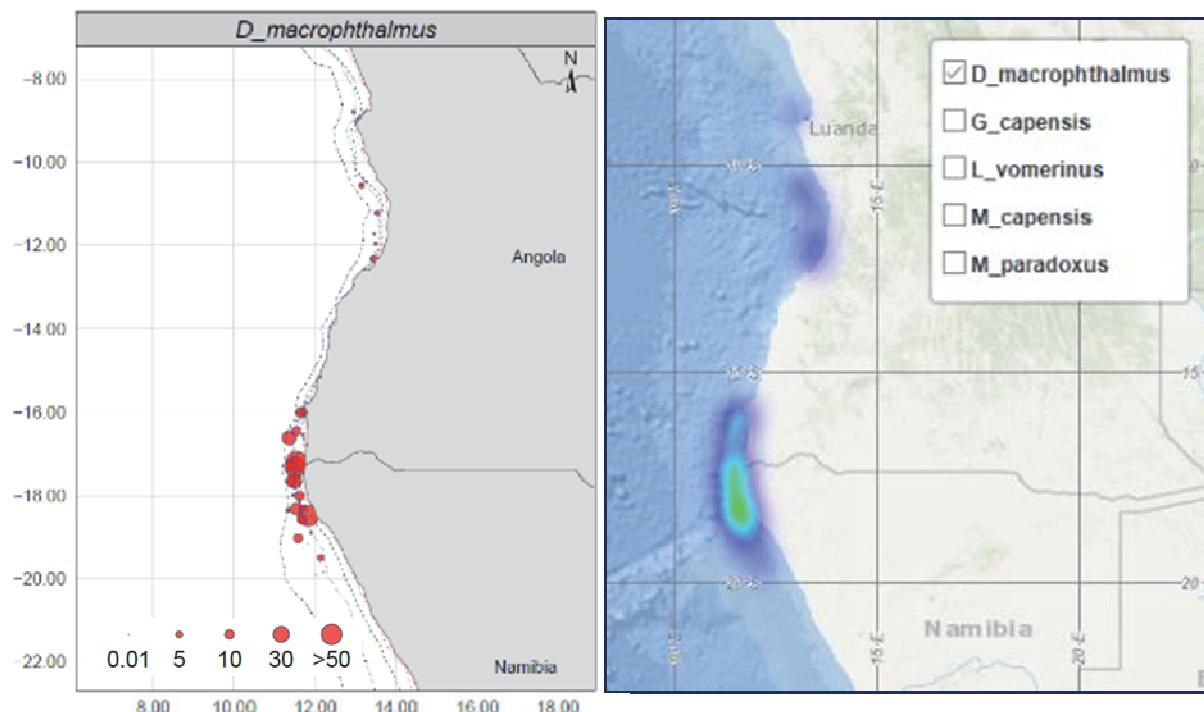

Figure 58. Distribution map for *Dentex macrophthalmus* showing trawl catch rates (CPUE) in tonnes/NM² (left panel) and as a density heat-map (right panel)

The CPUE data are presented in 5 cm length-classes (Figure 59, note that other species are presented in 10 cm length-classes). The smallest fish, less than 15 cm (upper left and central panels) were only observed in northern Namibia and the southern part of Angola. As the fish became larger greater and greater densities occurred in central Angola, and less in southern Angola and northern Namibia (top right panel and left and central panels in middle row). Virtually all the fish occurred off central Angola by the time they had reached 31 cm, although at a low density.

This pattern could indicate that the northern part of the Namibian coast and southern Angola is a nursery area for Dentex, with larger fish migrating northwards as they grow. These data do not suggest that large fish return southwards to spawn in the nursery area. Further analysis of these and other data are needed to investigate how the young fish arrive at the nursery area.

Large-eyed dentex is an important target fish species for the artisanal and industrial fisheries of Angola. If Namibia were to start encouraging harvesting of dentex, this could have an important impact on the sustainability of this transboundary stock. Hence understanding the dynamics of any possible cross-border movements is important.

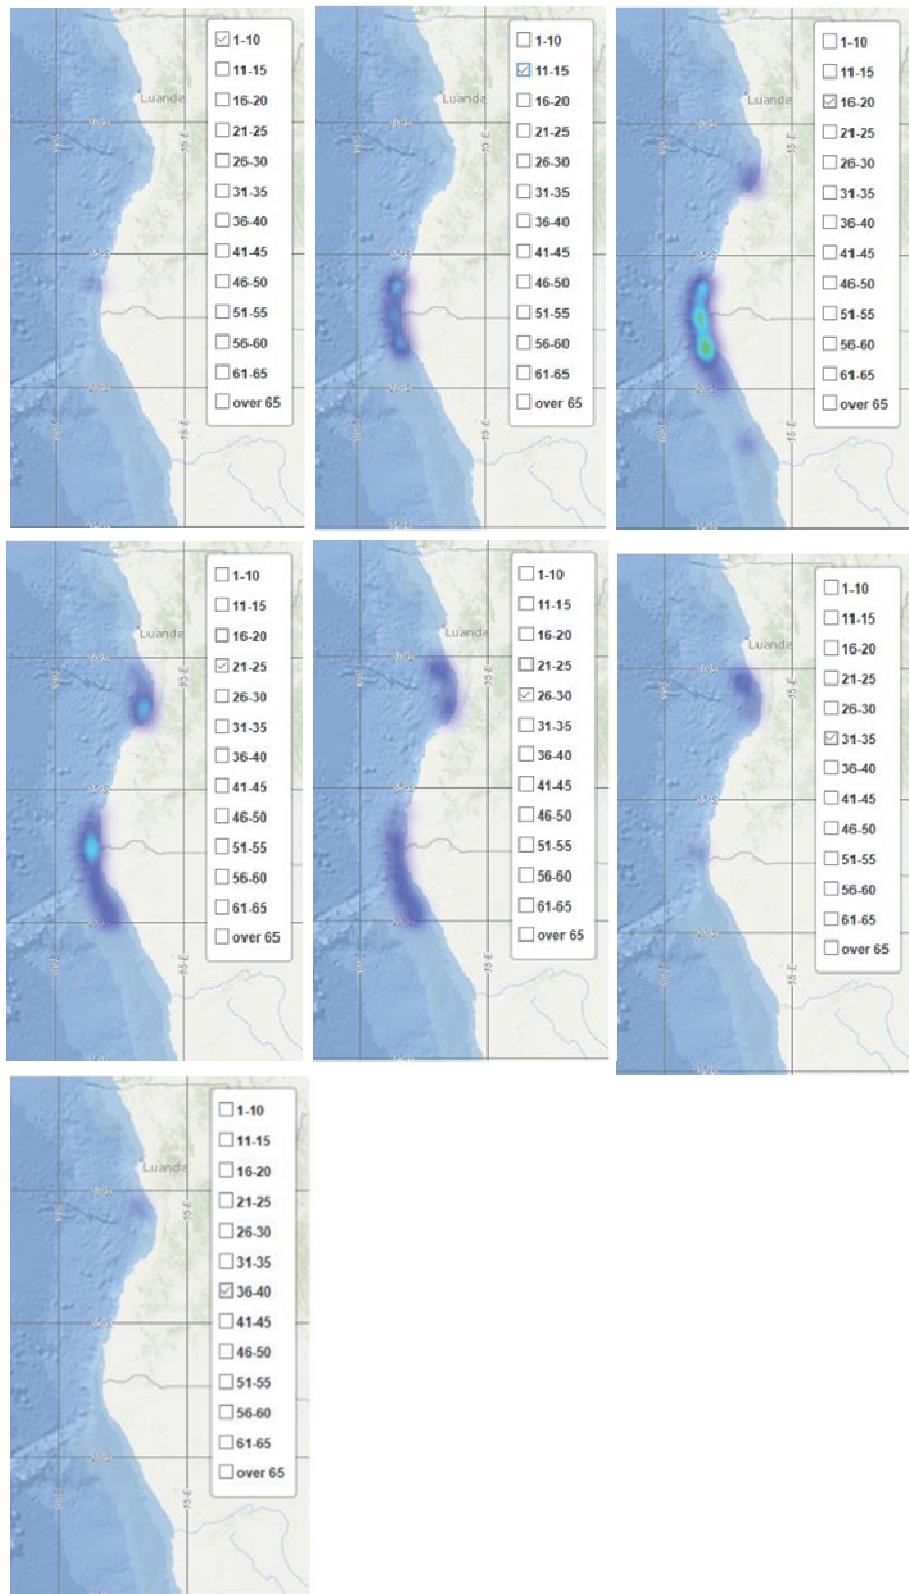

Figure 59. *Dentex macrophthalmus* distribution in 5 cm length classes. Base map data sources: GEBCO, NOAA, CHS, OSU, CSUMB, National Geographic, DeLorme, NAVTEQ and Esri

ANNEX III. HYDROGRAPHY SENSORS AND WATER CHEMISTRY QUALITY ASSURANCE

pH, chlorophyll- α and phaeopigment samples were measured in duplicates (or greater if a value appeared suspect). Total alkalinity samples were measured in triplicates.

Parameter	Sample count	Average Coefficient of Variation
pH	122	
Total alkalinity	122	
chlorophyll- α	196	
Phaeopigments	196	

CTD dissolved oxygen and salinity value validity statistics

Parameter	Sample Count	Average Coefficient of Variation
Dissolved Oxygen	28	
Salinity	0

ANNEX IV. OVERVIEW OF SAMPLING PROCEDURES IN THE PLANKTON LAB

All manta samples should be sorted on board
 Sorting of manta samples can be done even after preservation

Processing of MANTA samples (335 µm net)

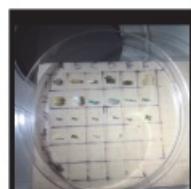

Microplastics

1. Put the sorted items in a small petri dish with **fresh water**

2. Put a **lid (labelled with station number)** and keep it safe until processing (you may do it the day after)

3. Place the items on a gridded petri dish

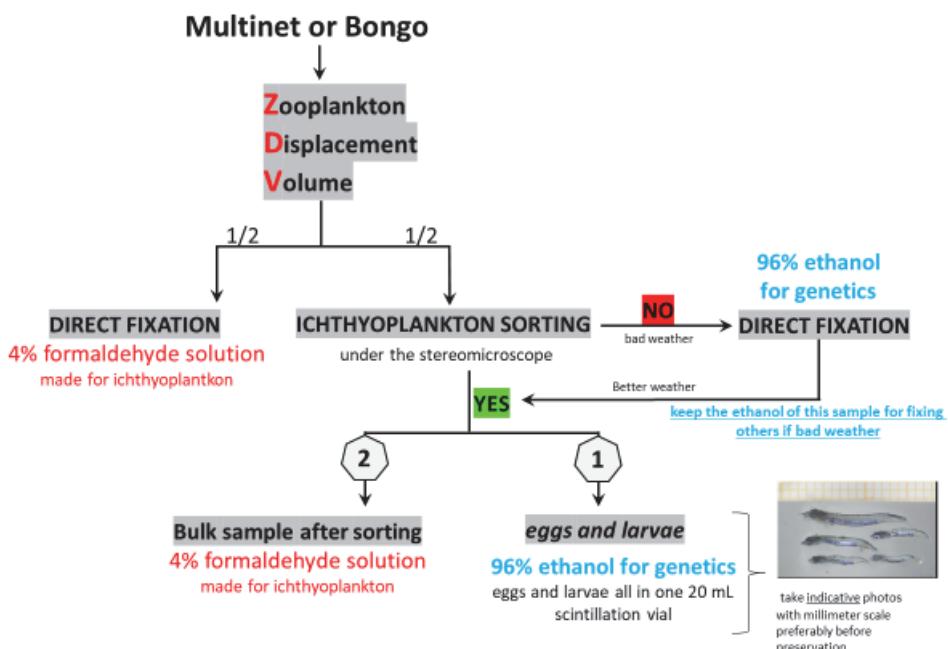

4. Take a photo of the entire dish with the **millimeter paper** below

5. Measure the dimensions of each item and fill the logsheet

Processing of ichthyoplankton samples (405 µm net)

Zooplankton Displacement Volume (ZDV)

- Pour the sample into a 250 or 500 ml graduated cylinder (depending on the volume of plankton present)
- Fill up the cylinder with sea water up to max (250 or 500 mL)
- Pour the sample through a 180 um sieve, and collect the sea water in a second cylinder to measure its volume

*Allow the sample to drain well before measuring the volume of water!
Do not add extra water to rinse plankon any remainings in the cylinder!*

- The difference between the two volume measurements is the Zooplankton Displacement Volume. Note it down in the comments of the sampling logsheet
- **Collect all the zooplankton**, both from the sieve and the remainings in the first cylinder and continue with the SAMPLE PROCESSING

ANNEX V. DESCRIPTION OF ACOUSTIC INSTRUMENTS AND FISHING GEAR

Acoustic instruments

The Simrad EK80/18, 38, 70,120, 200 and 333 kHz scientific sounder was run during the survey. Scrutinizing was done in LSSS using the data from the 38-kHz transducer. Last standard sphere calibrations were checked on the 23.01.2017 in Sandviksflaket, Bergen, Norway using Cu64 for the 18 kHz, Cu60 for the 38 kHz, WC38.1 for the 70, 120 and 200 kHz, and the WC22 for the 333 kHz. The details of the settings for the 38-kHz echo sounder were as follows:

Transceiver2 menu (38 kHz)

Transducer depth 5 8 m

Absorption coeff. 8.3 dB/km

Pulse duration medium (1,024ms)

Bandwidth 2.43 kHz

Max power 2000 Watt

2way beam angle 20,6dB

Gain 26,95 dB

SA correction 0.03 dB

Angle sensitivity 21.9

3 dB beamwidth 6.22° along ship

6.28 athwart ship

Alongship offset 0.10°

Athwardship offset 0.06°

Bottom detection menu Minimum level 50 dB

Fishing gear

The vessel has one small four-panel Åkrahamn pelagic trawl, one MultPelt 624 trawl (Figure V.1, new in 2017) and one 'Gisund super bottom trawl'. The Gisund trawl was the only gear used during the survey.

The bottom trawl has a 31-m headline and a 47-m footrope fitted with a 12" rubber bobbins gear. The codend has 20 mm meshes, and has an inner net with 10 mm mesh size. The vertical opening is about 5.5 m. The distance between the wing tips is about 18 m during towing. The sweeps are 40 m long. The trawl doors are 'Thyborøen' combi, 8 m² and weigh 2 000 kg. The door spreading is about 45 m when using restraining rope. Trawling was conducted for species identification only and no restraining rope was therefore used during the survey.

The SCANMAR system was used during all trawl hauls. This equipment consists of sensors, a hydrophone, a receiver, a display unit and a battery charger. Communication between sensors and ship is based on acoustic transmission. The doors are fitted with sensors to provide information on their interdistance and angle, while a height sensor is fitted on the bottom trawl to measure the trawl opening and provide information on clearance and bottom contact.

The all trawls are equipped with a trawl eye that provides information about the trawl opening and the distance of the footrope to the bottom. A pressure sensor is used to show the depth on the headline.

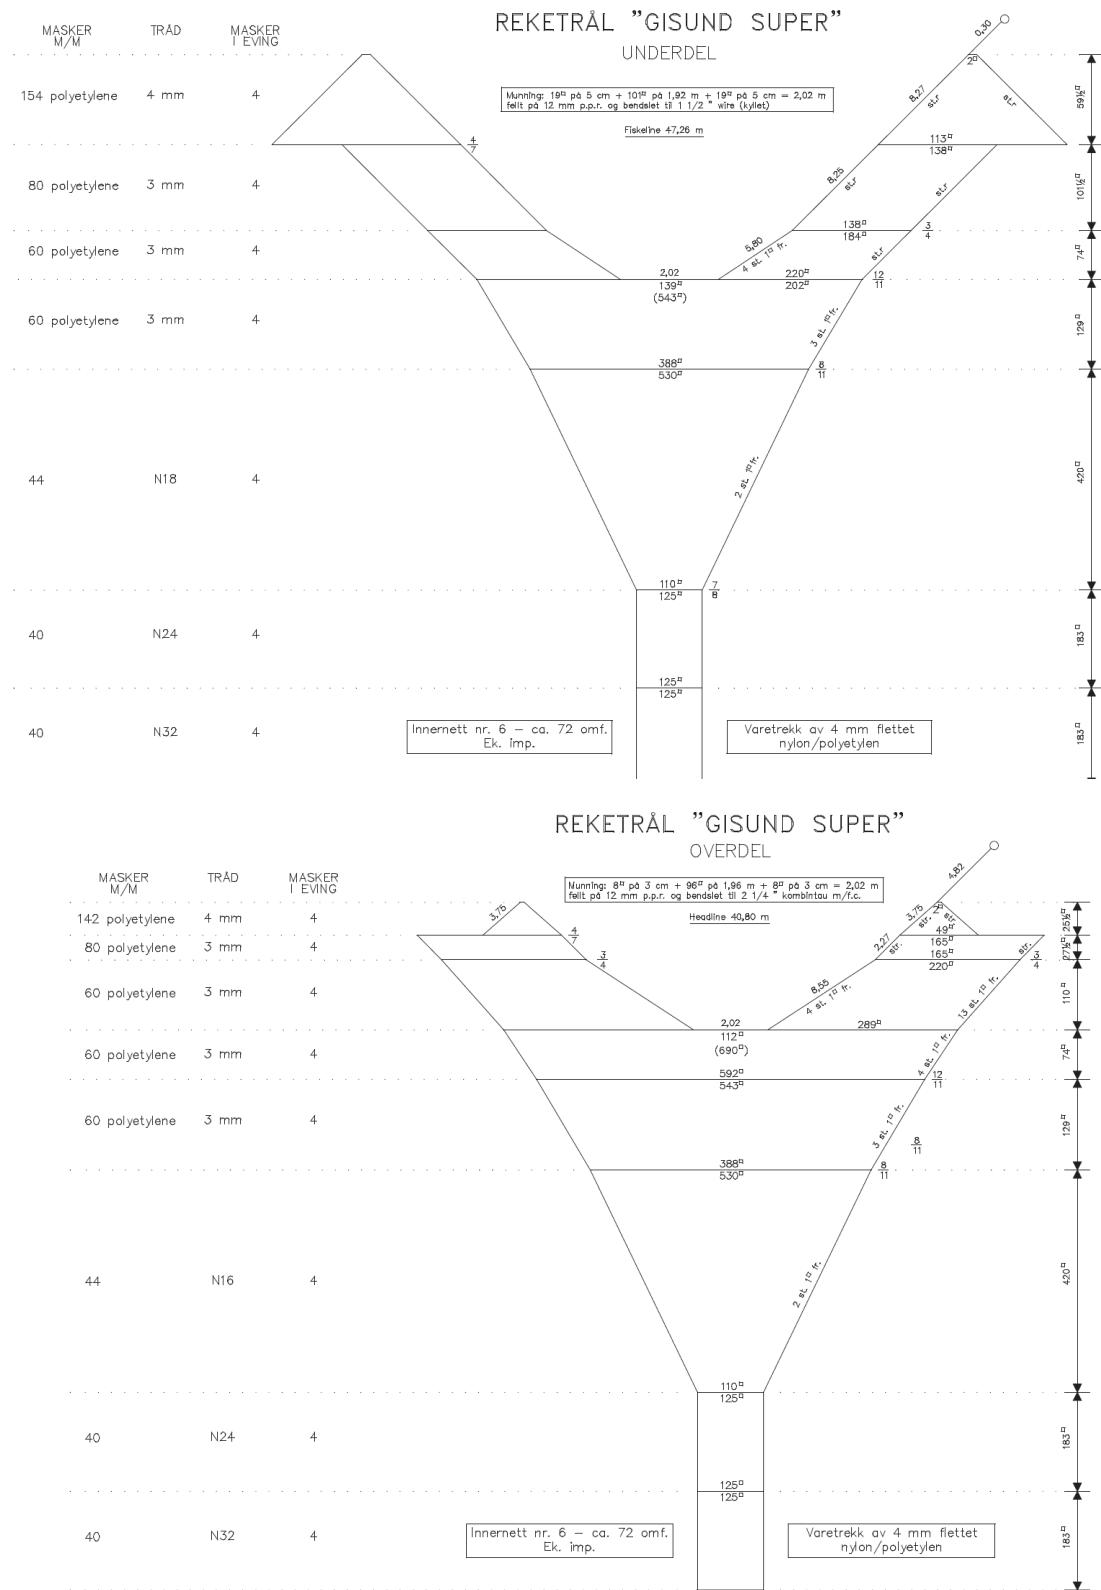

Figure V.1. Schematic drawing of the Super Gisund bottom trawl

ANNEX VI. SUMMARY OF TRAWL STATIONS, CATCHES AND OCCURRENCE OF FISH ABOVE THE TRAWL HEADROPE

Transect	Trawl No.	Start trawl				Total catch	Species composition of pelagic component	Acoustic marks above headrope	Comments
		Lat	Long	Depth	Date				
Orange River	1	28 40	16 12	99					Untrawlable ground - not attempted
	11	28 51	15 53	165	10.04.2019	05:15	447 kg	74% hake, 3% Pel 1, 19% mycto, 4% other	No fish

ANNEX VII. BIOLOGY SCALES

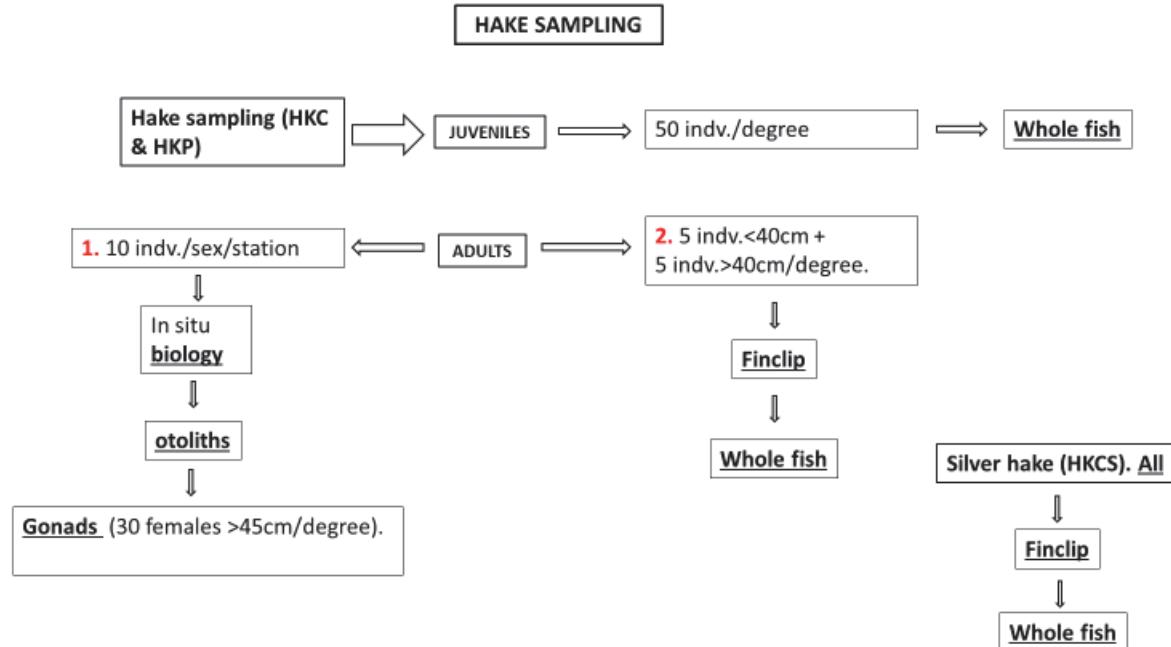

Sexual maturity

Stage	State	Description
I	Immature	Ovary and testis about 1/3rd length of body cavity. Ovaries pinkish, translucent, testis whitish. Ova not visible to naked eye.
II	Maturing virgin and recovering spent	Ovary and testis about ½ length of body cavity. Ovary pinkish, translucent, testis whitish, symmetrical. Ova not visible to naked eye.
III	Ripening	Ovary and testis is about 2/3rds length of body cavity. Ovary pinkish yellow colour with granular appearance, testis whitish to creamy. No transparent or translucent ova visible.
IV	Ripe	Ovary and testis from 2/3rds to full length of body cavity. Ovary orange-pink in colour with conspicuous superficial blood vessels. Large transparent, ripe ova visible. Testis whitish-creamy, soft.
V	Spent	Ovary and testis shrunken to about ½ length of body cavity. Walls loose. Ovary may contain remnants of disintegrating opaque and ripe Ova, darkened or translucent. Testis bloodshot and flabby

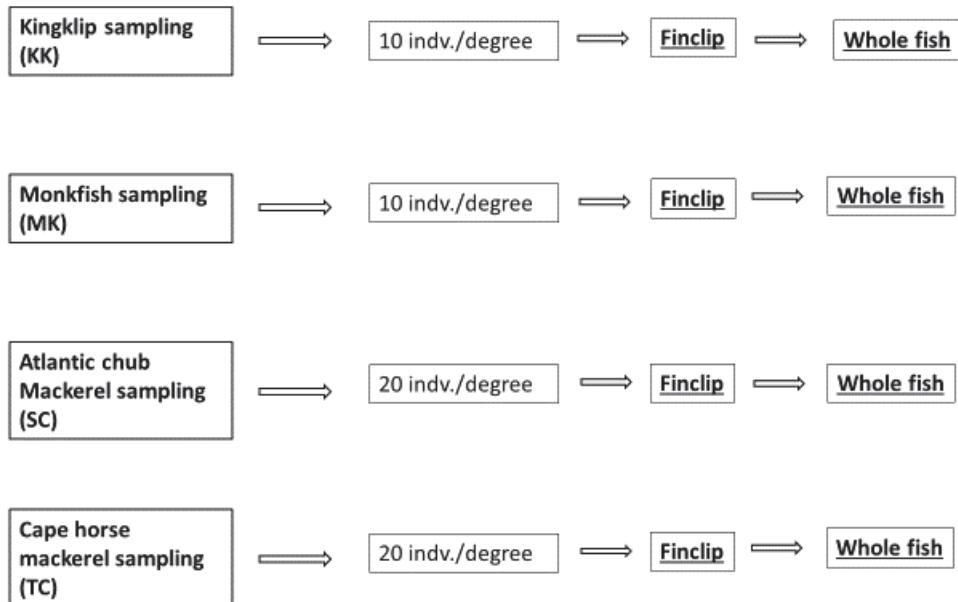

Stomach contents

Scale	Designation	Description
0	Empty	Stomach empty except for water.
1	Very little content	Stomach is almost empty. Only traces of small organisms can be found.
2	Some content	Stomach not completely full and not dilated.
3	Stomach full	Stomach full, but not bloated/dilated.
4	Bloated/dilated	The stomach is visibly expanded and tight. Content can be observed from the outside.

ANNEX VIII. OVERVIEW OF SAMPLING PROCEDURES IN THE FISH LAB
